The fineſt horſes known in Europe are the Arabian: they are larger and fuller than the Barbs, and not inferior to them in ſhape. But as few of them are imported into France, the riding maſters have not made any circumſtantial obſervations on their perfections and defects. The Barbs are more common, their cheſt is long and ſlender, riſes beautifully from the withers, have little manes, the head well ſhaped, ſmall and lean; the ears handſome and well placed; the ſhoulders flat and ſlender; the withers narrow and plump; the back ſtrait and ſhort; the flank and ſides round, and not bellying out; the haunches firm, and well ſhaped; the croup or breech generally ſomewhat long, and the tail pretty high placed; the thigh well ſhaped, and ſeldom flat; the legs handſome, well ſhaped, and without hair at the paſtern joint; the foot well made; but the paſtern often long. They are of all colours, but generally brown. The Barbs are ſomething negligent in their goings; but, properly encouraged, ſhew an amazing ſwiftneſs and vigour: they are very light, and fit for running; and ſeem, of all others, the fitteſt to breed from. It were, however, to be wiſhed that they were of a taller ſize, the very largeſt being only fourteen hands; and one of fourteen hands and an inch is very extraordinary. Experience has ſhewn that in France, England, &c. they get colts larger than themſelves. Among the Barbs, thoſe of the kingdom of Morocco are accounted the beſt, except the mountain Barbs. Thoſe of the reſt of Mauritania are inferior to them, as are alſo thoſe of Turky, Perſia, and Armenia. All horſes from a hot climate have a ſmoother coat than others. The Turkiſh horſes are not ſo well proportioned as the Barbs; the neck ſlim, a long body, and the feet too ſlender; but are very laborious and long winded. Nor will this appear ſtrange, if it be conſidered, that in hot countries the bones of animals are harder than in the cold; and for this reaſon it is, that though their ſhank bones are ſmaller than the horſes of this country, yet their legs are ſtronger.

The Spaniſh horſes, which are placed next to the Barb in rank, have a long thick neck, with a large mane; the head full large, and ſometimes the fore-top large; the ears long,

long, but well placed; the eyes full of fire, and the air noble and ſpirited; the ſhoulders thick, and the cheſt broad; the back often ſomething low; the ribs round, but the belly often too large; the croup generally round and large, though in ſome longiſh; the legs beautiful and without hair; the ſinew well detached; the paſtern ſometimes longiſh like the Barbs; the foot a little lengthened like that of a mule; and the heel often too high. The fine bred Spaniſh horſes are plump, well-ſet, and place the legs well on the ground; they have alſo a great deal of motion in their paces; great agility, fire, and ſtatelineſs. Their coat is generally black, or a light cheſnut; though there are ſome of all the uſual colours. But it is very ſeldom that any are ſeen with white legs or muzzles; the Spaniards having ſuch a diſlike to theſe marks, that they never breed from horſes which have them. A ſtar in the forehead is all they require; but they value horſes of one intire dark colour as much as we deſpiſe them: both theſe prejudices, though oppoſite, are perhaps equally ill founded, there being very good horſes with all kinds of marks; and ſome excellent among thoſe which are all of one colour. This minute difference in the coat does not proceed from the nature or conſtitution of the horſe; but from an external, and at the ſame time ſo ſuperficial a quality, that a ſlight wound in the ſkin is ſufficient to produce a white ſpot: further, the Spaniſh horſes, whether intirely of one colour, or not, are all marked on the off-thigh with the mark of the ſtud where they were bred. They are not uſually large ſized; though ſome riſe to fourteen hands and one or two inches. Thoſe of Upper Andaluſia are eſteemed the beſt of all, though they are apt to have the head too long; but this blemiſh is overlooked in conſideration of their excellent qualities; as courage, gracefulneſs, obedience, ambition; and in activity, they even exceed the Barbs. Theſe advantages recommend them above all other horſes in the world, whether for war, ſtate, or the manage.

The fineſt Engliſh horſes greatly reſemble the Arabians and Barbs in ſhape; indeed they owe their origin to them; but the head is much larger, though well made, and has a fine fore-top; the ears longer, but properly placed. By the ears alone an Engliſh horſe may be diſtinguiſhed from the Barb: but the greater difference is in the ſize; the Engliſh horſes are much larger and well-ſet. Their common height is fourteen hands two inches, and even fifteen hands is not very extraordinary. They are all colours, and all marks; are generally ſtrong, mettleſome, bold, bearing great fatigue, excellent for hunting and racing, but want air and agility; they are ſtiff, and have little freedom in their ſhoulders.

The Italian horſes were formerly much finer than at preſent, the ſtuds having been neglected there for ſome time paſt: the kingdom of Naples, however, ſtill affords fine horſes, eſpecially for carriages; but they have, in general, large heads and thick necks: they are alſo untractable, conſequently are difficult to be trained. Theſe defects are, however, in ſome meaſure, compenſated by the largeneſs of their ſize, their ſpirit, and the beauty of their motions. They are excellent for parade, and very much affect ſtatelineſs.

The Daniſh horſes are of ſuch a large ſize, and ſo well ſet, that they are preferred to all others for coach horſes: ſome are perfectly well moulded, though in general their formation is not very regular; moſt of them having a thick neck, broad ſhoulders, the back a little too long and low; and the croup too contracted for the breadth of the cheſt; but they all move well, and are in general excellent for war and ſtate. They are of all colours, even the moſt uncommon; the pye and ſpotted being ſeldom ſeen but in Daniſh horſes.

Germany affords ſome fine horſes, but the generality are heavy and thick winded; though moſt of them come from Turkiſh and Barbary horſes, of which there are many ſtuds; as alſo of Spaniſh and Italian horſes: thus they make no figure in hunting and racing; whereas the horſes of Hungary, Tranſylvania, &c. are very light and fleet: the Huſſars and Hungarians ſlit their noſtrils, with a view, it is ſaid, to mend their wind, and, at the ſame time, to prevent their neighing in the field; it being affirmed that horſes, whoſe noſtrils have been ſlit, cannot neigh. It has not indeed been in my power to examine this particular; but it ſeems natural to think, that the operation can only weaken their neighing. The Hungarian, Croatian, and Poliſh horſes are noted for having what is called the mark in all their fore teeth, which continues to old age.

The Dutch horſes are very good for coaches, and are moſt commonly uſed in France. The beſt come from Friezland. The countries of Bergue and Juliers alſo breed very good ones. The Flemiſh horſes are far inferior to thoſe of Hôlland; they have generally large heads, broad feet, and their legs ſubject to dropſical ſwellings. The two latter are capital faults in coach horſes.

France produces horſes of all kinds, but not many which may be called fine. The beſt ſaddle horſes come from the Limoſin, being ſomething like the Barb, and excellent hunters, but of a ſlow growth. They muſt not be broke young, nor put to any ſervice till they are eight years old. Auvergne, Poitou, and the territory of Morvant, in Burgundy, alſo produces very good ponies. But Normandy, next to Limoſin, affords the fineſt horſes; and if not ſuch excellent hunters, they are preferable to the reſt for war, are better ſet, and ſooner trained. Lower Normandy and Cotentin, are famous for very fine coach horſes; they are lighter, and more ſprightly than the Dutch horſes: Franche-compté, and the Boulonnois furniſh very good draught horſes; but a general fault in the French horſes, is the width of their ſhoulders; whereas thoſe of the Barbs are too much contracted. *Buffon.*

Though the moſt experienced horſemen are not always agreed in ſome points relating to the ſhape, make, and goings of a horſe, yet they almoſt always accord in this, that there ought to be a juſt proportion in all his parts. That even when he is taken to pieces, and examined ſingly in his particular members, though ſome defects may appear, yet when they all bear a juſt correſpondence one to another, and concur in ſuch a manner as to render his action eaſy, juſt, and regular; ſuch a horſe cannot be greatly diſagreeable, but will, for the moſt part, move well, and with a tolerable good grace. On the other hand, ſuppoſe a horſe has ſome parts exquiſitely fine, and others indifferent, which frequently happens, it will mar his beauty, and cauſe him to look diſagreeable, and for the moſt part affect his gait and action.

In order to have a horſe beautiful and finely made, it has been agreed, on all hands, that his head ſhould not be long nor too large, rather lean than fleſhy; his ears thin and narrow, and of a becoming length, well ſet on, pointing inwards; his brow or forehead not too broad and flat; his noſe ſomewhat riſing, and of a good turn; his noſtrils wide and thin; his muzzle ſmall; his mouth neither deep nor too ſhallow, with a ſtar or ſnip down his

forehead, or a blaze, which is no way unbecoming, unleſs it be too large and diſproportioned.

Horſes that are thus marked have generally one or more of their feet white, which is alſo very beautiful, and looks lively. His jaws ſhould be thin and ſufficiently wide, not approaching too near together, nor two high upwards towards the onſet, that he may have ſufficient room to carry his head eaſy, and in good place. His eyes well formed, ſprightly, and of a middle ſize. His neck ſhould be arched towards the middle, ariſing by a beautiful gradation out of his breaſt and ſhoulders, the muſcles thereof diſtinct, but no where overcharged with fleſh, growing ſmaller and thinner, as it approaches towards his head. His ſhoulders ſhould be thin from the withers, with a grudual enlargement downwards, that his boſom or breaſt be not too narrow nor too groſs. His fore-legs ſtraight and well placed; his joints lean and bony; his knees not bending, and his paſterns not too long; his feet round and ſmooth, and his ſinews firm and well braced; his carcaſe rather round than flat; his back not too low, and for ſtrength and durableneſs pretty even and ſtraight. His ribs rather home than open, as they approach towards his haunches; his buttocks round, and the muſcles not too fleſhy but diſtinct; his hocks or gambrels neither ſtanding too wide, nor too near together; his hocks ſhould be lean and no ways puffed or fleſhy; his paſterns ſhort, his legs flat and thin, and his tail ſet in a good place, rather high than low, riſing upon every motion of his body. The more theſe properties concur in any horſe, the more beautiful he muſt be, eſpecially when they correſpond and agree in due proportion, one to another; and the more a horſe is wanting in theſe, the more plain and ordinary he will appear.

HORSE-HOE, *ſee the article* CULTIVATOR *and* HOE.

HORSE-HOEING, the operation of cultivating plants according to the principles of the New Huſbandry; viz. by hoeing the intervals or alleys between the rows of corn, and by that means ſupplying the plants with freſh nouriſhment.

"I have tried, ſays M. de Valliers, to hoe my alleys after M. de Chateauvieux's method, which I look upon as the beſt and moſt expeditious; notwithſtanding that ſeveral difficulties which I have met with in the practice of it, have obliged me to give it up. For example, the great furrow in the middle of the alley is, according to his directions, to be filled up by two turns of the plough, one on the right-hand, and the other on the left, after which it is to be opened again by one turn of the cultivator with two mould-boards, or two or three turns of the common plough.

"When I ſet about this work, the firſt turn of the plough, if the ſhare went to any depth worth ſpeaking of, always filled up the furrow in ſuch manner, that to prevent its being poached by the horſes, I tried to make them walk on one ſide, upon the upper-ground, and conſequently very near to the rows of corn: but then, in the firſt place, I could not avoid the deſtruction of a great number of plants, without giving ſuch attention as was not only exceſſively troubleſome, but almoſt impracticable: and ſecondly, I could plough only the ſurface; becauſe, as the furrow was filled, the plough could turn up but very little earth, without being choaked, and becoming extremely heavy.

"If, to ſave the plants, I made the horſes tread partly upon the mould turned over into the furrow, the plough choaked equally, and for the ſame reaſon, whenever the furrow was cut deep. All I could do in this caſe, was to give only a ſuperficial ploughing: and with that it was impoſſible to uſe the cultivator with two mould-boards, to form the furrow, becauſe that inſtrument cannot work in any but a looſe well-tilled ground.

"All theſe inconveniencies may not happen in a ſoil different from mine. I am the more inclined to think this, as M. de Chateauvieux certainly does not experience them: but at the ſame time I muſt likewiſe obſerve, that this juſtly celebrated gentleman has inſtruments ſo perfect, and directs his ſervants with ſuch ſuperior judgment, that few can expect eaſily to equal him in the practice of the New Huſbandry.

"Not being able, for the above reaſons, to do with one turn of the cultivator with two mould-boards, what, as M. de Chateauvieux himſelf obſerves, can frequently not be done with leſs than three or four turns of the common plough, which, added to the two turns that are given to fill up the furrow, make in all five or ſix bouts, I purſued, and with great advantage, nearly the method before deſcribed. I ſay nearly that method, becauſe I have made ſome few alterations, by which I think it is rendered both eaſier and better.

"1. I make the mould-board twelve or thirteen inches deep, inſtead of nine or ten that it was before. The furrows are by this means made wider, and the plough is more eaſily drawn, becauſe it finds more room to diſcharge its load of earth in, and ſuffers leſs preſſure.

"2. To give the ſecond hoeing with the plough, inſtead of continuing to turn the earth over towards that ſide of the alley where only one furrow was turned up at the ending of the firſt ploughing, I, on the contrary begin this ſecond at that furrow, approaching, if poſſible, to within two or three inches of the row of corn, and then I make a furrow in the contrary direction, which turns the earth up againſt that row.

"My reaſon for ploughing ſo near the rows, when I give this ſecond hoeing, is, that I have obſerved that the rains which fall pretty frequently in the ſpring, between the firſt ploughing and the ſecond, harden the earth greatly, and that drought afterwards hardens it ſtill more, ſo that the roots of plants can no longer pierce or ſpread in it with eaſe; and yet nothing is more neceſſary, in order to their being benefited by every culture of the earth, than that they ſhould find an eaſy paſſage into the mould which lies next to the rows. It is therefore highly proper to ſtir that mould, when the ſecond hoeing with the plough is given, which, with me, is when the corn has begun to ſpindle; that being the time when the plants ſhoot with the greateſt vigour, and when their roots ought conſequently to begin to extend to ſome diſtance.

"I have not perceived that the plants have been at all damaged by the plough's coming ſo near them. They ought to be ſo much the leſs hurt thereby, as the rows are placed over a furrow which has been cut deep; a ſituation which, alone, is capable of making the corn tiller, and puſh ſtrongly: though the aſſiſtance of culture is likewiſe neceſſary, to ſupply the ſtalks and ears with plentiful nouriſhment.

"I am the better pleaſed with this method of bringing the hoe-plough almoſt cloſe to the rows, as it facilitates a very

very important operation ſtrongly recommended by M. Duhamel, and which I never before thought practicable: I mean, the raiſing up of the earth about the bottom of the plants; as well to give them greater nouriſhment, as to prevent their being lodged. The following is my method on this occaſion.

"When I fill up the furrow which I have cut as cloſe as poſſible to the row, I hold the plough ſloping, in ſuch manner that the earth is forced away from it, and is raiſed up about the plants. If this ſlope is not ſufficient, which may ſometimes depend on the condition of the ground, or the dexterity of the ploughman, I, in that caſe, make the mould-board two or three inches wider, when I uſed to fill the furrow, than it was when I made that furrow: and to this end I ſcrew on to the extremity of the mould-board, a thin plate of iron about four or five inches wide. Thoſe who practiſe the New Huſbandry in ſo extenſive a manner as to employ ſeveral ploughs, will find no inconvenience in having one, larger than the reſt, purpoſely for this important operation. As I do not give this ſecond hoeing with the plough, till after the corn has begun to ſpindle, it is eaſy for me to avoid burying the plants, eſpecially if there are no great clods in the ground: but, at all events, I always earth the plants up as much as poſſible, when there is no other danger than that of burying here and there a few of them, becauſe that accident is eaſily remedied afterwards, if it be worth while.

"When I am to give the third hoeing with the plough, I conſider the condition of the ground. If it is in good tilth, well looſened, and free from weeds, I uſe only the cultivator: otherwiſe I uſe the plough, three or four turns of which are ſufficient to perform this operation in the following manner:

"The firſt cut turns the earth over into the middle furrow: the ſecond and third are in a contrary direction; and the fourth takes up what was looſened by the third, whereby the furrow is replaced in the middle of the alley. Some time after this, and eſpecially if a ſhower of rain has fallen, I cut that furrow ſtill deeper, by one turn of the ſingle or double cultivator, as M. de Chateauvieux directs.

"But as, even after all theſe ploughings, the great furrow may chance to be neither deep enough, nor ſufficiently cleared of mould, owing either to the imperfection of the inſtrument made uſe of, or to the inaptitude of the ploughman, that defect may eaſily be remedied after harveſt, by giving one ploughing more, which is to be begun by throwing up the earth to the right and left towards the ſummit of the beds; that is to ſay, over the ſtubble. This practice is alſo confirmed by M. de Chateauvieux's inſtructions.

"The one ploughing extraordinary which this operation requires, ought not to be thought much of; becauſe the moſt important point in the New Huſbandry certainly is, the providing of a good depth of well ſtirred mould, for the plants to extend their roots in."

HOT-BEDS, beds of earth enriched with manure, in order to forward vegetation, when the ſeaſon or climate is not warm enough for the purpoſe.

By means of hot-beds, ſkilfully managed, the ſeeds of plants, brought from any country between the tropics, may be made to flouriſh even under the poles.

Heat and humidity being the great inſtruments of vegetation, to promote the growth of any plants, theſe muſt be duly proportioned, ſo as neither to exceed nor come ſhort of the bounds nature has allotted for it.

The uſual way of making hot-beds, is of horſe litter and graſs mixed together, and left on a heap for eight or ten days to putrify, and then removed into a bed, and covered up with glaſſes.

For raiſing cauliflowers, cucumbers, melons, radiſhes, and other tender plants and flowers in January or February, Mortimer directs to provide a warm place, defended from all the winds, by being incloſed with a pale or hedge of reeds or ſtraw, about ſix or ſeven feet high. Within this raiſe a bed two or three feet high, and three feet over, of freſh horſe dung, about ſeven or eight days old; then tread it down very hard, make it level, and, if you will, edge it round with boards or brick, laying fine rich mould about three or four inches thick on it. When you find by your finger, that the extreme heat of the bed is over, plant your ſeeds at pleaſure, and ſet your forks four or five inches above the bed, to ſupport the frame, and cover with ſtraw or mat, to ſecure the ſeeds and plants from cold and wet; only uncover them in a warm day, an hour before noon, and cover them again an hour after. Obſerve to earth up your plants, as they ſhoot up, and, when able to bear the cold, tranſplant them.

In Holland they uſe hot-beds made of ſand; and likewiſe of tanners bark, which, when once rightly prepared, will maintain an equable heat for ſix months.

Bradley propoſes very juſtly a thermometer to be uſed to regulate the heat of the hot-beds. Thus, a hot-bed for cucumbers muſt be kept ſo hot as to raiſe the ſpirit in a glaſs to the ſame height as the natural temperature of the weather will raiſe it about the end of May and June, when cucumbers will grow without artificial heat or ſhelter.

HOVEL, a ſhed open on the ſides, and covered overhead.

HOVEN, a diſeaſe common to cattle, on eating too greedily of green clover. It conſiſts in the paunch of the creature being ſwelled to a very great degree, which often, if not prevented, puts an end to the creature's life. The ſureſt method of curing this terrible diſeaſe, is that of making an inciſion into the paunch of the beaſt, and by that means the wind, which cauſed the ſwelling, will eſcape through the orifice, and the creature recover.

A correſpondent of the editors of the Muſeum Ruſticum has given the following account of his performing this operation.

"I took, ſays he, a ſharp-pointed pen-knife, and fixing my eye on the moſt prominent part of his belly, thruſt the blade through the integuments quite into the abdomen: there iſſued out a great guſt of wind very fetid, with ſome water of a rediſh colour; the bullock ſeemed eaſier, but far from well; for the wound preſently cloſed up, and admitted no more air to eſcape; ſo that I was under the neceſſity of ſtabbing him twice more in different parts of the belly before he was thoroughly relieved, which, by the help of a clyſter after the laſt ſtab, was preſently brought about: and here give me leave, gentlemen, before I leave this ſubject, to give a few cautions to thoſe who may be under the neceſſity, one time or other, of performing this very uſeful operation: reflection and experience warrant me in them, therefore I ſhall freely proceed.

"Firſt then, if it be performed with a pen-knife, not to be fearful in puſhing in the blade a proper length, till you find wind iſſue out; for if the wind be in the cavity of the belly, you cannot poſſibly hurt the gut, the whole body,

body of the wind being between you and it, which no reaſonable bladed pen-knife can touch; and if the wind ſhould be pent up in the inteſtine, you muſt penetrate it before the beaſt can be relieved. To this laſt, perhaps, it may be objected, that we run the hazard of killing the beaſt by wounding the gut; but I am far from thinking ſo, as I have ſeen many wounds of the inteſtine, both in man and beaſt, very happily cured: yet granting there might be ſome danger in it, ſtill we are certain, if the poor beaſt can get no relief, it muſt die; and ſo circumſtanced, ſurely, gentlemen, a doubtful remedy is better than none at all.

"Another caution is, that where theſe wounds are made in the belly with a proper pen-knife, it is not adviſeable to have them ſown up; for where there is a continual motion or action, as there is in the muſcles of the belly and parts adjacent, ſuch a practice is not only unwarrantable, but cruel; and why ſhould we not behave with humanity to the brute ſpecies, as well as any other?

"My laſt caution and advice is, that upon all theſe occaſions, when the beaſt is relieved of his wind, a proper clyſter ſhould be thrown up immediately, as hot as he can bear it: theſe clyſters ſtrangely relieve them, by acting as a warm, comforting bath to their diſtempered bowels, and emptying the ſame of the load of muck within them."

HOVER-GROUND, light ground.

HOUSE-BOTE, an allowance of timber out of the lord's woods, for the repairs of a houſe.

HULLS, the chaff, or huſks of corn.

HURDLES, are certain frames made either of ſplit timber, or of hazel-rods, wattled together, to ſerve for gates in incloſures, or to make ſheep-folds, &c.

HURDS, or *Hords* of flax or hemp, the coarſer parts ſeparated in the dreſſings from the tear or fine ſtuff.

HURLE-BONE, in a horſe, a bone near the middle of the buttock, very apt to go out of its ſockets with a hurt or ſtrain.

HUSBANDRY, the buſineſs or employment of a farmer, or perſon who cultivates land, &c.

Huſbandry is divided into two kinds, and diſtinguiſhed by the epithets old and new. The former is that which has been practiſed in all countries from the moſt early times; and the latter that introduced by the ingenious Mr. Tull, and often called the horſe-hoeing huſbandry.

Experience ſhews, that land, though ever ſo well tilled in the autumn, when wheat, for example, is ſown, hardens and ſoddens in the winter; its particles, beaten down by heavy rains, and ſunk by their own weight, approach each other daily more and more; the roots of the plants cultivated have conſequently leſs and leſs room to extend themſelves in queſt of their neceſſary food; and their interſtices in the earth become of courſe ſo few and cloſe, that they are not able to pierce through them, whilſt weeds ſpring up, and rob them of their nouriſhment. By this means the earth, reduced to nearly the ſame condition as if it had not been ploughed at all, is unable to aſſiſt the plants ſown in it in the ſpring, when they ought to ſhoot with the greateſt vigour. They conſequently then ſtand moſt of all in need of the plough to deſtroy the weeds, to lay freſh earth to their roots in the room of that earth which they have exhauſted, to break the particles of the ground anew, ſo as to enable their roots to ſpread, in order to their gathering an ample proviſion of food, which then does them the greateſt ſervice.

In the common huſbandry, the whole attention is to provide a great ſtore of nouriſhment for the wheat, at a time when it ſcarcely conſumes any, as it then produces only a few blades, after which it is left to itſelf, at a ſeaſon when it might, and ſhould be moſt aſſiſted by proper culture; a management as prepoſterous as it would be to give a child a great deal of food, and diminiſh it gradually as he grows bigger; or, to uſe Mr. Tull's compariſon, to give ſilk-worms, before they are hatched, treble the full ſtock of leaves neceſſary to maintain them, till they have finiſhed their ſpinning, and not to allow them any when they really want being fed.

The great advantage of having land in fine tilth before it is ſowed, is univerſally acknowledged: but we muſt not ſtop at thoſe firſt preparations. Plants require a continuation of culture while they grow, and muſt not be forſaken till they have attained their full maturity.

Thoſe who are againſt the frequent ploughings uſed in the New Huſbandry, are afraid of drying the earth too much; becauſe, ſay they, the moiſture eſcapes more eaſily from a well looſened ſoil, than from a hard and cloſe earth.

In anſwer to this it will appear from many of the following experiments, that, even in the drieſt weather, land cultivated according to the new method, continues conſtantly moiſter than that which is managed in the old way. Inſtead of a ſtagnant wet, more hurtful, perhaps, than beneficial, to plants; each made fine to a good depth, is prepared, as the reverend Dr. Elliot expreſſes it, "with open mouth, to drink and retain the dew, which, when it falls upon the land that is untilled, or but poorly tilled, does not ſink far, but is carried off by the next ſun's heat." That dew is one of the greateſt fertilizers of the earth, has been repeatedly proved; and that it will penetrate ſo deep in a fine looſe ſoil, as to keep that moiſt, while the ground badly tilled is parched up, appears, among many demonſtrations, from Mr. Evelyn's experiment of digging a hole, and filling it up with its former mould well pulverized: or, as Mr. Tull obſerves, till a field in lands; make one land very fine by frequent deep ploughings, and let another be rough, by inſufficient tillage, alternately: then plough the whole field croſs-wiſe in the drieſt weather, which has continued long; and you will perceive, by the colour of the earth, that every fine land will be turned up moiſt; but every rough land will be as dry as powder, from top to bottom.

Another proof of the benefits which ariſe from ſtirring the ground well and often between plants, while they grow, and conſequently a confirmation of the fundamental principle of the horſe-hoing huſbandry, is thus drawn by Dr. Elliot, from the common manner of raiſing Indian corn.

"The land, ſays he, being previouſly prepared, planted, and the corn come up, we plough a furrow off from the corn on each ſide, then hoe it, and the next time plough up to the corn; ſo that this tillage is nearly the ſame as is now propoſed for wheat, or whatever we would plant: only by the way, I would obſerve, that the ploughings between the rows, for Indian corn, is ſo ſhallow, that one would be apt to think it intended for nothing more than merely to kill the graſs and weeds; whereas it is found by experience, that, though there be neither graſs nor weeds, the ploughing and hoeing will make the corn grow, and that the more the land is ploughed and hoed, the better

and

and longer it will reſiſt drought, and yield the better crop: nay, what is ſtill more remarkable, if the Indian corn be well tilled, the next crop, whether it be oats or flax, will be proportionably greater and better; ſo that the land muſt have gained ſtrength and richneſs. If it were not ſo, why did not the Indian crop exhauſt and ſpend the ſtrength of the land, eſpecially when we conſider how large that corn is made to grow by good tillage? But we find the contrary; the better the crop of Indian corn, the better the crop will be of oats. There is no ſort of huſbandry, wherein the ſuperior force and virtue of tillage doth ſo evidently appear, as in the raiſing of Indian corn: for if you ſhould plough and harrow the beſt of land, and ſow or plant the corn, and never do any thing more to it, there will be leſs corn than if you ſhould plant poor land, and tend it well: the poor land well ploughed and hoed, ſhall bring a greater crop than the rich land. We hereby ſee the efficacy and advantage of this repeated tillage, which falls in ſucceſſively, according to the exigency and want of the plant in its ſeveral degrees of growth, and keeps the land in a proper ſtate. Why ſhould it not have the ſame effect upon wheat, and every other plant that is ſuſceptible of the like culture?"

If ſeveral rows of wheat are ſown in a poor but well ploughed land, the blades of the corn will turn yellow in the ſpring, eſpecially in dry weather. Let the earth bordering upon theſe rows be ploughed deep, in ſome places near, and in others farther from the rows, and the plants will reſume their proper colour; firſt in the places neareſt to the new ploughed ground, and afterwards gradually in the others, according to their diſtance; which proves that they recover their verdure, in proportion as their roots reach the looſe mould. This holds equally true in all plants; for Mr. Tull declares, that he does not remember ever to have ſeen a poor one contiguous to a well-hoed interval, unleſs overpowered by a too great multitude of other plants, an exception which muſt be equally made if it were a plant that required more or leſs heat or moiſture than the ſoil or climate afforded; and that, on the contrary, he has ſeen plants grow to an amazing ſize, when the earth around them has been frequently tilled. He mentions, among others, a plant of ray-graſs, which chanced to ſtand in a turnip field, where, being hoed as the turnips were, it acquired a bulk at leaſt equal to a thouſand plants of the ſame ſpecies; and a plant of muſtard, which grew higher than he could reach, ſo as to be more like a tree than an herb.

The ſtirring of the earth about the plants whilſt they grow, is productive of ſuch excellent effects, that, in ſome parts of Berkſhire, and in many places in France, they hand-hoe their corn, particularly wheat, and find that the crops amply repay all the charge and trouble of this expenſive operation; which, however, cannot be performed but in well-peopled countries. Every huſbandman will immediately ſee, how much a hoe-plough is preferable for this work, and that, to uſe it rightly, the corn muſt neceſſarily be planted in regular rows, as it is in the New Huſbandry.

Our reaſon tells us, that the longeſt lived plants ſtand moſt in need of this culture. Perennials require it more than annuals, and wheat which is ſown in autumn, and does not ripen till nine months after, want it more than ſpring-corn, which occupies the ground only for a few months. The former has to conquer a ſoil rendered hard during the courſe of the winter; but the other has not that difficulty to ſurmount, though both of them, and indeed all ſorts of plants, are greatly invigorated by the repeated laying of fine freſh earth to their roots. Every one knows the vaſt efficacy of wood land, before its native ſtrength and vigour are exhauſted; and ſuch, in ſome degree, is that which this tillage furniſhes; beſides being conſtantly attended with the advantage of deſtroying weeds. How far this laſt important part of agriculture was well executed by the ſarcling, or farriſon, as Mr. Tull calls it, of the ancients, we ſhall not pretend to ſay, becauſe we have no clear account of the manner in which it was performed; but it does not ſeem to have been in any way equal to the horſe-hoeing huſbandry, which likewiſe, among its many other excellencies, keeps the land from going out of tilth.

We ſhall here add Mr. Duhamel's obſervations on the uſe of dung, as given by that gentleman in his Elements of Agriculture.

"It is often, ſays he, more advantageous to increaſe the fertility of land by ploughing, than by dung: 1. Becauſe, in general, only a certain quantity of dung can be had, the product of twenty acres being ſcarcely ſufficient to produce enough for four or five; whereas the particles of the earth may be divided and ſubdivided almoſt to infinity. The help derived from dung is therefore limited; whilſt no bounds can be ſet to the benefits that may accrue from ploughing.

"2. Few plants raiſed in dung ever have the fine flavour of thoſe which grow in a good ſoil moderately dunged. Our kitchen gardens and our other grounds afford daily inſtances of this truth. Pulſe, pot-herbs, and fruit, are ſeldom ſo good in the neighbourhood of great cities, where dung abounds, as in country gardens, where but little of it is uſed. The corn raiſed in thoſe exceſſively dunged lands, yields a great deal of bran, and not much fine flour, and is difficult to keep. Nice horſes will not eat oats of the growth of fields manured with human ordure. But nothing is ſo ſtriking as the difference between the wine of an undunged vineyard, and that of vines which have been greatly dunged.

"3. Dung, which is ſuppoſed to act by fermentation, cauſes indeed an inward diviſion of the particles of the earth, which muſt be very uſeful, as well as the food which it furniſhes to plants: but the plough, beſides dividing thoſe particles, changes their ſituation, and turns the ground upſide down, ſo that the part which was expoſed to the influences of the air and dews, takes the place of another part which is brought from within the earth, up to its ſurface. The conſequence of this is, that well ploughed land is not exhauſted by weeds, and that it admits the moiſture of rains and dews, together with the rays of the ſun, all of which contribute greatly to render it fertile, as has been proved by very many experiments.

"4. Dung attracts inſects, and thoſe inſects gnaw plants. It is well known that the roots of trees planted in dunged ground, are very liable to be damaged by inſects: and this is one of the chief reaſons why floriſts baniſh dung from their gardens. Worms, grubs, and other ſuch like vermin, make dreadful havock in their beds of flowers; and I have ſeen meadows where the graſs has been entirely deſtroyed, by their eating its roots.

"I muſt add, that moſt ſorts of dung contain a great many ſeeds which fill the land with ſeeds.

"5. It

"5. It is true that dung is equally ſerviceable to light lands, and to ſtrong; but the ſame may be ſaid of ploughing.

"Land is too ſtrong when its particles lie ſo cloſe together, that the roots of plants cannot extend between them, without great difficulty in queſt of their neceſſary food; for want of which they will remain poor and ſickly: but when the ground has been well looſened by repeated ploughings, and its plants are ſet at greater diſtances from each other, thoſe roots will be able to ſpread freely on all ſides, to pervade every minute chaſm, and to collect ſuch quantities of food as will make the plants grow ſtrong and vigorous. The friendly influences of the atmoſphere will then penetrate to them. What plainly proves the good effects of looſening ſuch ſoils, is, that their fertility is ſometimes increaſed by a mixture of ſand, inſtead of dung. Now ſand does not afford any nutritive ſubſtance; but only hinders the particles of the earth from re-uniting too cloſely.

"Ploughing is equally beneficial to light lands, for the very contrary reaſon; though theſe do not require ſo much of it as the other. There is no danger of their being exhauſted by any expoſure to the ſun; but, on the contrary, they acquire an additional degree of fertility by the ſtirring and grinding of their particles, and are thereby the better fitted to receive the moiſture of rains and dews, and the ſalutary influences of the air and ſun; whilſt their inward pores are at the ſame time better adapted to the proper extenſions of the roots of plants, by their being leſſened.

"But let the benefits ariſing from dung be ever ſo great, let the means of obtaining enough of it be ever ſo eaſy, and let even its defects be corrected as much as can be, ſtill it will not be the leſs true, that frequent ploughing is of infinite ſervice to land.

"For this reaſon it is, that land entended for wheat is ploughed three or four times before the grain is ſowed. Some farmers, who could not dung all their lands, ploughed part of them double the uſual number of times, and reaped greater crops from theſe, than from thoſe which were dunged. The expence of the ploughings extraordinary will be much leſs than the price of the dung neceſſary for the land, if the farmer is obliged to purchaſe it.

"In 1759, M. Delu gave three ploughings to ſome of his fields intended for oats; and though that year was very dry and unfavourale to ſpring corn, his oats kept up well till they were perfectly ripe, and yielded a full crop of excellent grain.

"He gave five ploughings to a piece of wheat-land which had not being dunged, and at harveſt, had taller and finer corn there, than in the neighbouring grounds which had been dunged and cultivated in the uſual way. In ſhort the advantage of thorough tillage, while the plants are growing, is ſo great, that, in many places, it has been found amply to repay even the expence of digging between the rows of corn.

"The farmer muſt not think of practiſing the New Huſbandry in land which cannot be brought to a fine tilth: for as no remedies are proper for all diſeaſes, ſo no one culture can ſuit every kind of ſoil.

"I have met with very zealous huſbandmen, who have been in a great hurry to procure all the inſtruments proper for the horſe-hoeing huſbandry, before they had examined whether their ground was fit for uſing them. In walking over the fields, I have found them in ſo bad order as to be full of clods, ſtones, and all ſorts of weeds: only the bare ſurface of the land had been ſcratched, by what they called ploughing; and indeed their common inſtruments of tillage were ſo imperfect, that it was hardly poſſible for them to do more. I adviſed them to deſtroy thoſe weeds by good and frequent ploughing, to procure good inſtruments, to looſen the ground to a proper depth, to collect good manures, to drain their land well by trenches and ditches, and, in ſhort, to practice the Old Huſbandry completely, before they attempted the new; for, in fact, all the requiſites in the former muſt be the foundation of the latter.

"To anſwer the ends of this huſbandry, the ſeeds muſt be diſtributed ſo ſparingly, that each plant may have room to extend its roots in ſuch manner, that they may be able to collect an abundant quantity of food; each plant muſt be enabled to tiller greatly, ſo as to produce a conſiderable number of ſtalks; and each ſtalk muſt be enabled to bear a fine long ear, well filled with grains to its very point.

"To effect the firſt of theſe qualities, the field, after being thoroughly ploughed and well harrowed, muſt be divided by furrows, the ſpaces between which may be of ſuch breadth as ſhall be judged moſt proper; for neither their preciſe width, nor the diſtance between the rows of corn, is yet fully determined. In the middle of theſe ſpaces, which will be diſtinguiſhed by the name of beds; the wheat, or other grain, is to be ſown in one, two, or more rows. An inch will be ſufficient for the diſtance between the grains, lengthwiſe of the row; though that may be ſomewhat leſs, if the ground be not very good for wheat; or, on the contrary, ſomewhat more, if it be excellent for that grain. By this diſtribution, each plant will find, in the intermediate ſpaces between the beds, and in the beds themſelves, a ſufficient extent of earth wherein to collect its neceſſary food; for thoſe intermediate ſpaces, which I ſhall call alleys, muſt be wide enough to admit of ſtirring the ground in them while the plants grow: but to anſwer the ſecond and third intentions, it is of conſequence that theſe ſtirrings be performed at proper ſeaſons, becauſe each of them is to produce its particular effect.

"It is eſſentially neceſſary that the rows of corn be ſown very ſtraight; a circumſtance which, though it be attended with ſome trouble, ought not to diſcourage the huſbandman, becauſe the great difficulty will be only the firſt time. After the ground has been once rightly ſown, it will be eaſy to continue in the ſame regular tract every following year, without taking the precautions I am now going to obſerve.

"If the field be not very large, a furrow traced with a ſpade or pickax, directed by a line ſtretched acroſs the ground, will enable the ploughman to guide the horſe that draws the drill; and he will take care to leave a proper interval between one furrow and another, if three rows are to be ſown.

"If the extent of ground be too great for the above method, poles or ſtakes may be ſtuck, five feet aſunder, at each end of the field, to guide the ploughman, who, with a common plough, will trace ſmall furrows, by the help of which the horſe and drill may be properly directed.

"It will be right, if poſſible, to ſuit the direction of the furrows to the declivity of the land, that the water

may

may drain down to the loweſt part of the field, where a ditch ſhould be dug to carry it off: and it will alſo be neceſſary, to make them lengthwiſe of the field, if convenient, that the leſs ground may be loſt by the ſpace which muſt be left for the plough to turn in.

" After the ſeed is put into the hoppers of the drill, the horſe which draws this inſtrument muſt be made to walk ſlowly in the furrow before traced by way of guide: and in order to drop as nearly as poſſible the intended quantity of ſeed, the outlet of the hopper muſt be proportioned to the ſize of the grain.

" As it will be ſomewhat difficult to manage the drill rightly at firſt, till the huſbandman becomes uſed to it, he ſhould look over his field as ſoon as the corn has ſprouted, and then drop by hand a few grains in the places where it may have failed.

" The land ſhould be ſown about the middle of September, or, at fartheſt, by the end of that month: and it will be right always to try the goodneſs of the ſeed beforehand, by ſowing fifty or an hundred grains of it in a fine mould, or moiſt ground, where it will ſoon appear whether they all riſe.

" Land which retains water ſhould be ploughed once in October, when the weather is fine. In doing this, a furrow ſhould be firſt cut in the middle of the alleys, and then it ſhould be filled with the earth on each ſide, even ſo far as to arch it up, and leave only a ſmall furrow on either ſide, cloſe to the beds, to drain off the wet, which would prove very prejudicial to the plants if it were to remain long near their roots. This looſening of the earth will alſo fit it for being mellowed by the winter's froſts; to which, however, care muſt be taken not to expoſe the roots of the corn, by leaving them too bare of mould. The moſt proper time for this ſtirring of the ground is when the plants have ſhot out ſome blades.

" The ſecond horſe-hoeing, which ſhould be given as ſoon as the hard froſts are paſt, that is to ſay, by the end of March, is intended to make the plants tiller; and will have this effect, if, after the earth near the rows has been ſtirred a little, that which was before laid up in the middle of the alleys be returned back to the furrows at their ſides. This earth, having been mellowed during the winter, will afford excellent nouriſhment to the plants now beginning to vegetate apace, and they will ſoon put forth their multiplied ſtalks.

" The third hoeing, which is the ſecond after winter, and is intended to ſtrengthen the ſtalks, ſhould be performed when the ears of the corn begin to appear. This culture, which is looked upon as the leaſt important of all, and is ſometimes even omitted without any great inconvenience, need not be any thing more than a ſlight ſtirring of the earth, in which it will however be right to begin to hollow the alleys.

" The laſt ſtirring of the earth between the rows of corn is one of the moſt important, being that which makes the grains ſwell, and grow full bodied to the very point of the ear. The moſt proper time for this is, when the ears begin to bloom: but as the corn is then high, only one furrow can be cut in the middle of the alleys, the earth of which ſhould be laid up to the ſtem of the plants on each ſide. The plough will hardly be able to paſs more than twice in this furrow, which ſhould, however, be made as deep as poſſible, in order to bank up the greater quantity of earth. By this operation, the now fallow alleys are prepared for the next ſowing; for it is in the middle of them that the corn is to be planted the following year; and the now eared wheat is earthed up, to preveut its being lodged; though in general corn thus cultivated is leſs apt to be beaten down, than that which is raiſed in the common way, becauſe the ſtraw of this being more expoſed to the air, becomes harder and acquires a firmer texture, eſpecially toward its bottom. It is for this reaſon that a tuft of corn, which ſtands quite ſingle, is ſcarcely ever beaten down by the weather.

" Theſe repeated hoeings of the earth will certainly be rewarded with a very plentiful crop, unleſs the ſeaſons prove extremely bad.

" When the corn is reaped, all poſſible care ſhould be taken not to trample upon the adjoining ploughed ground.

" It is well known, that vigorous plants do not ripen their ſeeds ſo ſoon as thoſe which have been ſtinted in their growth: for this reaſon the corn cultivated according to the principles of the New Huſbandry, ripens later than in the common way, and ſhould therefore be ſown ſomewhat earlier.

" We will now ſuppoſe that the crop is reaped, and that the ſame field is to be ſown again with wheat the next year, and every year after, as it may be, becauſe the rows of corn are placed each time in the middle of the former alleys, which have been ploughed during the whole year, without producing any thing. Thus, the only difference between this new method and the old huſbandry is, that inſtead of reſting, or fallowing, a whole field, whilſt another whole field is under corn, and each of them is ſeparate from the other; the fallow here is in the ſame field as the corn, being interpoſed by means of alleys, which are the part reſted between the beds, which are the part cultivated: but there is this great advantage here, that the ſtirring of the earth in the alleys, which are not planted, not only prepares the ſoil admirably for being ſown the next year, but invigorates the plants actually growing in the beds.

" If it be thought proper to dung the alleys, in order to prepare them for the reception of the ſeed, the dung, which ſhould be thoroughly rotten, muſt be laid in the bottom of the deep furrow before made in the middle of them, and there covered with the earth which was thrown up towards the rows of wheat. If the land does not want dunging, this deep furrow is filled up without it; and this ſhould be done immediately after harveſt, that there may be time to give the ground another ſtirring, which need only be a ſlight one, before the ſowing of the rows, which are now to be in the middle of the former alleys; and the alleys of this year will be in the place of the laſt year's ſtubble.

" Though land, cultivated according to the principles of the New Huſbandry, does not require ſo much dunging as that which is managed in the old way, yet this manure will always help to enrich the ſoil, eſpecially if it be uſed in the manner here directed. By being thoroughly rotten when it is laid in the furrow, and there covered over immediately after harveſt, it will have time to mellow and diffuſe its influence, and not be apt afterwards to choak up the ſhares of the drill; an inconvenience which does not happen with pigeons dung, which therefore need not be ſtrewed till the ground is ploughed for ſowing.

" It is farther obſerved:

" 1. That if dung be uſed for the ſecond year's crop, very little of it will ſuffice, becauſe it need only be laid in the bottom of the furrows.

" 2. That there can hardly be any occaſion for dung this ſecond year, becauſe, if the earth of the beds in which the wheat grew was good, that of the alleys, of the ſame ſoil, muſt be ſtill better, by reaſon of its having been fallowed and well tilled.

" 3. That the ſecond year's wheat is placed in a moſt advantageous ſituation, its roots having a depth of twelve or fifteen inches to extend themſelves in, by means of the furrow which was in the middle of the alley. For this reaſon, corn ought to thrive beſt in thoſe lands which have been longeſt cultivated according to the New Huſbandry.

" The earth in the alleys is to be horſe-hoed during the ſecond year, in the ſame manner, and at the ſame ſeaſons, as in the firſt.

" This frequency of hoeing ought not to be objected to; for the labour of the firſt hoeing, to make the furrows on each ſide of the rows, and lay the earth up in the middle of the alleys, cannot be great; and the ſecond only returns that earth into thoſe furrows: the third is only to ſtir the ſurface of the ſoil: the fourth and laſt is to make the deep furrow in the middle of the alleys, and bank up the rows of corn on each ſide, with the earth taken out of it; ſo that neither of theſe operations ever extends to above a third part of the ground, at any one time.

" The whole field might indeed be ploughed up after harveſt: but I would adviſe the huſbandman not to touch the ſtubble then, becauſe the rows of that will help him to guide the drill in ſtraight lines, and the yet unrotten ſtraw might be apt to clog the ſhares of the drill, ſo as to prevent their working properly. However, if the ſtubble be very ſhort, this caution becomes the leſs material, and the whole field may then be ploughed; though ſtill it will be neceſſary to plough it again in October, in order to make drains to carry off the wet.

" It is almoſt needleſs to obſerve, that all the operations of which I have been ſpeaking, muſt often be performed either a little earlier, or ſomewhat later, according as the year is more or leſs forward; and that it will always be neceſſary to wait till the ground is dry enough to be ploughed without danger of its clodding; a circumſtance which varies greatly, according to the nature of the ſoil."

The editors of the laſt edition of Mr. Tull's Horſe-hoeing Huſbandry, give, in their preface to that work, the following comparative calculation of the expence and profit of the old method of culture and the new, drawn up by a gentleman who has practiſed both for ſome years, and who has no attachment to the New Huſbandry, farther than he has found it anſwer in his trials. They candidly appeal to experience, " whether every article in this calculation is not eſtimated in favour of the common huſbandry; whether the expence be not rated lower than moſt farmers find it; and whether the crop be not ſuch as they would rejoice to ſee, but ſeldom do.

" In the New Huſbandry, every article is put at its full value, and the crop of each year is computed four buſhes ſhort of the other, though, in ſeveral years experience, it has equalled, and generally exceeded, thoſe of the neighbourhood in the old way."

An Eſtimate of the Expence and Profit of Ten Acres of Land, in Twenty Years.

I. In the Old Way.

	l.	s.	d.	l.	s.	d.
First year for wheat coſts 33l. 5s. viz.						
First ploughing at 6s. per acre ——	3	0	0			
Second and third ditto, at 8s. per acre	4	0	0			
Manure, 30s. per acre —— ——	15	0	0			
				22	0	0
Two harrowings and ſowings, at 2s. 6d. per acre —— ——	1	5	0			
Seed, three buſhels per acre, at 4s. per buſhel —— ——	6	0	0			
Weeding, at 2s. per acre ——	1	0	0			
Reaping, binding, and carrying in, at 6s. per acre ——	3	0	0			
				11	5	0
Second year for barley coſts 11l. 6s. 8d.						
Once ploughing, at 6s. per acre ---	3	0	0			
Harrowing and ſowing, at 1s. 6d. per acre —— ——	0	15	0			
Seed, four buſhels per acre, at 2s. -	4	0	0			
Weeding, at 1s. per acre ——	0	10	0			
Cutting, raking, and carrying, at 3s. 2d. per acre ——	1	11	8			
Graſs-ſeeds, at 3s. per acre ——	1	10	0			
				11	6	8
Third and fourth years lying in graſs coſt nothing.				44	11	8
So that the expence of ten acres in four years comes to 44l. 11s. 8d. and in twenty years to				222	18	4
First year's produce is half a load of wheat per acre, at 7l. per acre —— ——				35	0	0
Second year's produce is two quarters of barley per acre, at 1l. per acre ——				20	0	0
Third and fourth year's graſs is valued at 1l. 10s. per acre —— ——				15	0	0
So that the produce of ten acres in four years is				70	0	0
And in twenty years it will be ——				350	0	0
Deduct the expences —— ——				222	18	4
And there remains clear profit on ten acres in twenty years by the old way ——				127	1	8

II. In the New Way

First year's extraordinary expence is						
For ploughing and manuring the land, the ſame as in the old way ——				22	0	0
Ploughing once more, at 4s. per acre	2	0	0			
Seed, nine gallons per acre, at 4s. per buſhel ——	2	5	0			
Drilling, at 7d. per acre ——	0	5	10			
Hand-hoeing and weeding, at 2s. 6d. per acre ——	1	5	0			
Horſe-hoeing ſix times at 10s. per acre	5	0	0			
Reaping, binding, and carrying in, at 6s. per acre ——	3	0	0			
The ſtanding annual charge on ten acres is ——	13	15	10			
Therefore the expence on ten acres in twenty years is ——				275	16	8

Add

	l.	s.	d.
Add the extraordinaries of the firſt year, and the ſum is —— ——	297	16	8
The yearly produce is at leaſt two quarters of wheat per acre, at 1s. 8d. per quarter, which on ten acres in twenty years amounts to —— ——	560	0	0
Therefore, all things paid, there remains clear profit on ten acres in twenty years, by the new way —— ——	262	3	4

"So that the profit on ten acres of land in twenty years, in the new way, exceeds that in the old by one hundred and thirty-five pounds one ſhilling and eight-pence, and conſequently is conſiderably more than double thereof; an ample encouragement to practice a method whereby ſo great advantage will ariſe from ſo ſmall a quantity of land, in the compaſs of twenty-one years leaſe; one year being allowed, both in the old and new way, of preparing the ground.

"It ought withal to be obſerved, that Mr. Tull's huſbandry requires no manure at all, though we have here, to prevent objections, allowed the charge thereof for the firſt year; and moreover, that though the crop of wheat from the drill-plough is here put only at two quarters on an acre, yet Mr. Tull himſelf, by actual experiment and meaſure, found the produce of his drilled wheat crop amount to almoſt four quarters on an acre: and, as he has delivered this fact upon his own knowledge, ſo there is no reaſon to doubt of his veracity, which has never yet been called in queſtion. But that we might not be ſuppoſed to have any prejudice in favour of his ſcheme, we have choſen to take the calculations of others rather than his, having no other view in what we have ſaid, than to promote the cauſe of truth, and the public welfare."

A comparative Calculation of Expence and Profit between the Drill and the Common Huſbandry, taken from Mr. Baker's Report to the Dublin Society of his Experiments in Agriculture, for the Year 1765. *Publiſhed by Order of that Society.*

An Eſtimate of the Expence upon a Plantation * Acre of Wheat, in the Common Huſbandry.

	l.	s.	d.
To the firſt ploughing, commonly called breaking for fallow, 8 horſes, 8s. 2 ploughmen, 1 s. 4 d. 2 drivers, 1 s. ——	0	10	4
To the firſt harrowing, 4 horſes, 4 s. a driver, 6 d. —— ——	0	4	6
To the ſecond ploughing, commonly called gaurowing —— ——	0	10	4
To the ſecond harrowing —— ——	0	4	6
To the third ploughing, commonly called ſtretching —— ——	0	10	4
To ſowing the ſeed, 8 horſes, 8 s. 2 ploughmen, 1 s. 4 d. 2 drivers, 1 s. the ſeed-man, 8 d. —— ——	0	11	0
To ſeed wheat, one barrel ——	1	0	0
To rent for the year of fallow ——	0	18	0
To ditto, the year the crop is growing —	0	18	0
	5	7	0

In this account 40 s. are charged for 40 horſes, imployed in the culture of one acre for wheat, in the common huſbandry; a charge which ought to be conſidered by the farmer; for he actually buys and maintains his horſes for this buſineſs.

The crop which follows wheat is generally oats; but ſometimes peas are ſown inſtead of oats; with ſome, the practice is to let the peas follow oats; in which caſe they fallow only every fourth year; but where land receives no other aſſiſtance than what ariſes from fallow, it is a bad practice not to fallow every third year. It is the general practice to plough but once for oats; and therefore it ſhall be ſtated ſo; but it is a much better practice to plough the wheat ſtubble once before winter, and again in the ſpring.

An eſtimate of expence upon an acre of oats.

	l.	s.	d.
To ploughing once —— ——	0	10	4
To ſeed oats, 2 barrels —— ——	0	12	0
To harrowing, 4 s. 6 d. ſeed-man, 4 d. —	0	4	10
To one year's rent —— ——	0	18	0
	2	5	2

Theſe two crops conſume three years; after which the farmer is to begin again, and to incur every article of expence ſtated in the above accounts, in order to obtain two crops more.

* An Iriſh acre contains 7840 ſquare yards.

An Eſtimate of Expence upon a Plantation Acre of Wheat in the Drill Huſbandry, the firſt Year.

	l.	s.	d.	
To ploughing 4 times, to prepare the fallow -	2	1	4	This is the ſame charge as in preparing for the common huſbandry.
To harrowing twice for ditto ——	0	9	0	This is the ſame alſo.
To rent for the year of follow ——	0	18	0	This charge is ſaved after the firſt year.
To harrowing with the drill harrows ——	0	0	6½	Four acres a day may be harrowed with one horſe.
To ſowing with the drill plough ——	0	1	1	From three to five acres may be ſown in a day.
To ſeed wheat generally 5 ſtone, but ſuppoſe 6	0	6	0	
To the firſt, or winter hoeing ——	0	1	7	Two acres may be hoed in a day, two horſes, plough-man and driver: the deſign of this hoeing is to leave the plants dry, and to meliorate the earth.
To the ſpring hoeing with the cultivator —	0	1	1	To deepen the ſoil, one horſe, plough-man, and driver.
	3	18	7½	

	l.	s.	d.	
Brought over —	3	18	7½	
To the third hoeing, i. e. to return the meliorated earth to the corn ——	0	1	7	To make the corn tiller, i. e. to increaſe its branches.
To the fourth and final hoeing ——	0	1	1	To fill the grain, and render it large.
To rent, the year the corn is growing —	0	18	0	
	4	19	3½	

☞ Although the drill culture for the firſt year is very near as expenſive as the common; yet after taking the crop, the expence and labour of fallow, and the loſs of time, is not to be incurred again, as is unavoidable in the common huſbandry.

An Eſtimate of Expence upon an Acre of Drilled-Wheat after the firſt Crop.

	l.	s.	d.	
To ploughing the land once ——	0	10	4	One ploughing is all that is neceſſary,
To harrowing with the drill harrow ——	0	0	6½	
To ſowing with the drill-plough ——	0	1	1	
To ſeed-wheat —— ——	0	6	0	Be it remembered, five ſtone is enough.
	2	17	11½	Thus the land is ſown again with wheat every year,
To four times horſe-hoeing, as before ſtated	0	5	4	and inſtead of 4 l. 9 s. which is the farmer's expence in
To one year's rent —— ——	0	18	0	the common huſbandry, excluſive of one year's rent of
	2	1	3½	the land: in the drill method it is no more than 17 s. 11½d. and the total expence, inſtead of 5 l. 7 s. is no more than 2 l. 1 s. 3½d. rent included; whereby there is a ſaving of 3 l. 5 s. 8½d. an acre.

Before the account of profit and loſs upon theſe different methods of culture be ſtated, it will be neceſſary to take notice of an objection, which may perhaps be made to the above charge of ploughing in the common huſbandry.

It is pretended, that three quarters of an acre may be ploughed in a day, with one plough: but can it be done effectually? The land may, indeed, be ſcratched, but cannot really be ploughed as it ought to be.

The farmer ought to be cautioned againſt a trick too frequently practiſed in ploughing.

When a ploughman enters his plough and paſſes acroſs the field, he turns a ſod about a foot broad; when he is to return, he enters his plough about four feet diſtant from the outſide of the former furrow, and ſo turns another ſod of the ſame breadth, which, when turned, juſt meets the former ſod; thus four feet of the land appear to be ploughed, whereas the fact is, that the two feet lying under the ſods is not touched with the plough at all.

This deception, added to the practice of juſt ſkimming the ground, enables hirelings to undertake ploughing at ſix and ſeven ſhillings an acre.

But if a plantation acre of land be well and effectually ploughed, ten ſhillings and four-pence as charged above, will not appear too much; and it is, in fact, ſupported by the common courſe of buſineſs.

When wheat is to be ſown, it is the general cuſtom to ſend a barrel of ſeed into the field with two ploughs, which is to ſow an acre of land, and that is the uſual day's work for two ploughs in the general courſe of buſineſs.

Let us ſee then, what the expence will amount to: eight cattle will be eight ſhillings, two ploughmen one ſhilling and four-pence; two drivers one ſhilling, and the ſeed-man eight-pence, which in all makes eleven ſhillings, and correſponds with the above charge.

One Acre of Wheat and Oats in the Common Huſbandry, for fifteen Years.

To clear profit arising upon an acre of land in fifteen years in the Drill-Husbandry	——	52	3 11
To clear profit arising upon an acre of land in fifteen years in the common husbandry	——	27	19 2
Greater profit on the drilled acre in fifteen years	—— —— ——	24	4 9

Which amounts to 1l. 12s. 3¾d. *per annum*, for fifteen years on the acre, more than by the common husbandry.

In the drill-husbandry the crops are stated at three barrels of wheat less upon an acre than in the common husbandry, that it may not be supposed to be over-rated; but in the common husbandry, the crops are rated at the highest; fourteen barrels of oats an acre, are also allowed in the common husbandry, which every farmer must admit to be great allowance upon the general produce.

That the drill culture will produce six barrels an acre, is fully proved in Mr. Baker's report at large, which will shortly be published, where it will be shewn, that much more has been produced.

Doubtless it will be observed, that in fifteen years fourteen wheat crops are obtained in the drill-husbandy; in the common husbandry only five wheat and five oat crops; the other five years are not only lost, but are an heavy expence to the farmer.

A farmer having forty acres of tillage, supposing him to direct his attention to bringing it to the drill culture, would make in fifteen years 969 l. 10 s. more than he can in the common husbandry: which is such an advantage, that the greater profit in the drilled acre in fifteen years will purchase the fee simple of that in the common husbandry, at twenty-seven years purchase, valuing the land eighteen shillings an acre.

Thus it appears, that in every fifteen years the fee simple of all the tillage lands of the kingdom, is lost to the community by the common course of tillage

In stating these accounts, no mention is made of fences, water cutting the land, weeding and reaping, as these articles of expence depend upon a variety of circumstances: but will, in general, be more upon the common husbandry than the drill.

M. de Chateauvieux's *Account of the Crops produced during Sixteen successive Years, by Fields cultivated and sown in the common Way, and of which Part was constantly dunged; compared with a Crop of the same Fields cultivated without Dung, according to the New Husbandry.*

"The result of all our experiments in agriculture would be of little use, if it extended no further than our private instruction. To render it of more general service, we shall here give a comparison of the produce of lands cultivated according to the Old Husbandry, and according to the New, that every one may judge which of the two is most likely to answer best.

"This parrallel will shew how much the New Husbandry is superior in point of advantage to the Old. We are to suppose all the circumstances of the seasons to be like those of the years of which we have compared the products. But as the expence of culture is an object well worth considering, and as that expence may not be equal in both ways, I beg leave to lay down here as a fact, "That the charge of the new culture is less than that of the old." I have tried it, and find it so; as I shall, hereafter, prove beyond dispute.

"By the old culture, in the farm which I now cultivate in the new way, I should have had but two fields sown in 1752; to be reaped in 1753. These two fields contain together eighteen acres, two roods, and twenty-eight poles. I have calculated their produce during sixteen years, viz. from 1730, to 1745, inclusively. They have yielded, in that time, eight crops, the total produce of which has been 146863 pounds of wheat: deducting from which, 42130, pounds for the seed sown in the eight years, the neat produce will be reduced to 104733 pounds.

It is proper to observe that this wheat was measured every year in the barn, as soon as it was threshed, and before it was sifted: an operation which always occasions a considerable dimunition, though we do not make any allowance for it here.

"Let us now see what crops the preceding experiments

ments give us room reaſonably to expect from the ſame two fields in ſixteen ſucceſſive years of the New Huſbandry; to judge only by that of this firſt year, 1753, unfavourable as it is.

"The firſt field was ſowed, half in beds, and half in equally diſtant rows. I am obliged to ſuppoſe it to have been ſowed entirely in beds; for it cannot be doubted but that the part which was ſowed in rows, would have produced as much as the other: conſequently the whole crop of the two halves, at 3370 pounds each, would have been 6740 pounds.

"Beſides the advantage of reaping a much greater quantity of corn, there are others which highly merit our attention. This corn is not mixed with any ſeeds of weeds, and its quality is greatly improved by the abundance of nouriſhment which the plants are ſupplied with by the frequent ſtirrings of the earth in this huſbandry, more than in the old.

"But how fine a proſpect does the following propoſition afford us beyond all this! viz. "That the crops of the ſecond and following years, would be ſtill more plentiful than the firſt." What ſome might then think only an object of hope and ſpeculation, is already realized, and proved by experience. All this deſerves the moſt ſerious attention. The New Huſbandry will certainly, in time, acquire a ſuperiority over the Old, greater than we can now imagine.

Proofs that the beſt Field in the Country, though the greateſt Part of it was dunged, yielded leſs Wheat than thoſe in which no dung was uſed. By M. de Chateauvieux.

"The proofs of the advantages of the New Huſbandry cannot be too greatly multiplied; and all thoſe which are the reſult of experience, deſerve to be communicated to the public.

"The field we are going to ſpeak of, is generally, and juſtly, reckoned the beſt in the country. Its ſoil is excellent, very deep and extremely fertile. This field is dunged very often. Its nearneſs to the farm-yards renders the carriage of manure extremely eaſy, and is the cauſe of its getting perhaps more of it than may be neceſſary. Its ſituation too is excellent, riſing on all ſides above the neighbouring grounds, and the highways which ſurround it; by which means it is leſs expoſed to be hurt by wet, the water finding an eaſy drain from off it.

"The extent of this field 6087 fathoms (four acres and eight poles.) It was ſowed in 1752, for the harveſt of 1753, and the greateſt part of it was well dunged.

"It is not the cuſtom of the place I am ſpeaking of, to deſcribe the extent of a field by the number of acres contained in it, but by the number of meaſures of wheat with which is is ſowed. Eight meaſures uſed generally to be employed to ſow this: but the quantity of ſeed was leſſened this laſt time, and only ſeven meaſures were ſown. We have hitherto ſuppoſed the ſurface of this field to be equal to that of the other fields of the ſame country, in which eight meaſures of ſeed are ſown.

"But as I was deſirous to be more preciſely exact, in order to form the compariſon I purpoſed making, I had recourſe to the geometrical plans of the lands, and found the contents of this field to be, as I ſaid before, 6087 fathoms: now, the cuſtom of the village to which it belongs is always to ſow at leaſt eleven meaſures in a ſpace like this. One field, among others, very near to this, and which is but twenty-four fathoms and thirty-two feet larger, has always been ſown with twelve meaſures.

"A new cauſe of the fruitfulneſs of this field, unknown before my obſervations, is, that the farmer wiſely took care to ſow it with a leſs quantity of ſeed. The plants throve better, when the land was not over ſtocked with them. This field will therefore help to prove the truth of one of the firſt principles of the New Huſbandry, viz. that the quantity of ſeed generally uſed ought to be diminiſhed: a propoſition which deſerves our entire confidence, becauſe the ſeed here has, from time immemorial, been reduced to eight meaſures, and they have been ſufficient to produce very plentiful crops. The farther reduction made in 1752, to ſeven meaſures, muſt alſo be approved of, ſince the crop which theſe yielded was very fine.

"Theſe preliminary obſervations ſeemed neceſſary, before we proceeded in our detail. This field was ſowed with about 850 pounds of wheat. It was finer during the whole ſummer than any wheat in the common way. It was reaped at a proper time, and yielded about 6646 pounds, from which muſt be deducted, firſt, the 850 pounds of ſeed; and, ſecondly, the value of the dung, which is equal at leaſt to 1260 pounds of wheat, together with 2110 pounds; which deducted from 6646 pounds, the total produce, leave for the neat produce 4536 pounds.

"The crop of 1753 was diminiſhed by the hail on the third of June. The value of this loſs is not known; but we may fairly compare it with the experiment Numb. II. which likewiſe ſuffered by the ſame hail. We confeſs that this compariſon is not abſolutely exact, with reſpect to this accident; but it muſt alſo be granted, that this circumſtace cannot occaſion any very great error. We muſt likewiſe premiſe, that we ſhall not reckon the produce of a ſmall ſpot which is pretty commonly ſowed in March in the year of fallow, becauſe it hardly equals the expence of dung and ploughing.

"The neat produce on a field ſown in equally diſtant rows, was 2857 pounds eight ounces. But the extent of that field being only one acre, three roods, ſeven poles, and two yards, we muſt calculate what the crop would have been in proportion, if that extent had been four acres and eight poles (6087 fathoms) ſuppoſing it of the ſame quality. We ſhall find, that the field on which our experiment was made, would have produced neat 8006 pounds of wheat; deducting from which 4536 pounds, for the neat produce of the field cultivated in the old way. The difference in favour of the New Huſbandry, without dung, will be 3470 pounds of wheat.

"This field laid out in beds, yielded neat 1540 pounds of wheat. Its extent is but one acre, one rood, and eighteen poles; ſo that we are to ſee what crop it would have yielded if its extent had been four acres and eight poles, ſuppoſing the quality of the ſoil to be the ſame. The rule of three ſhews us again, that its neat produce would have been 5681 pounds of wheat, which we are to double for the amount of the next year's crop, every year yielding a crop in the New Huſbandry; whereas the field it is compared with would lie fallow this year. Thus two years will yield 11362 pounds of weat; from which deducting 4536 pounds for the neat produce of the ſame field, cultivated in the old way, during the ſame ſpace of time, the difference will be 6826 pounds of wheat in favour of the New Huſbandry.

Reflections

Reflections and Obſervations on the Practice of the New Huſbandry, by M. de Chateauvieux.

" The chief object of our reflection laſt year was, the effect which ploughing and culture have upon plants. They ſeem to us to be confirmed by the following obſervations.

" 1. The productions were greateſt in thoſe places where the earth had been moſt looſened, and brought to the fineſt tilth.

" 2. We have ſeen plainly, that, in order to improve our tillage, it is neceſſary to make the great furrow in the middle of the alleys very deep, becauſe that furrow being afterwards filled up, and a new bed made over it, there is a greater depth of light well looſened mould immediately under the roots of the plants.

" 3. We can affirm, that we have this year, without much trouble, ploughed our beds from fifteen to eighteen inches deep, which is very conſiderable; but we muſt not flatter ourſelves, that this depth can always be attained the firſt year; it is by continuing this ſame culture that we ſhall inſenſibly reach it.

" 4. To have great ſucceſs, requires proper care and judgment in performing every part of the New Huſbandry. The culture which is well executed, will be of very great uſe; but that, on the contrary, which is badly done, will be of no ſervice to the plants, and may even prove very detrimental to the next year's crop.

" 5. To perform this culture with advantage, it is therefore neceſſary to obſerve this important maxim of tillage, ſo little attended to by many farmers, " never to ſet the plough to work, when the earth is too moiſt." I have adhered to it ſtrictly, and have never ſuffered my lands to be touched till they were dry. We have tilled when the weather has been very dry and very hot, and then it was that our culture had the beſt effect; the ſtiffeſt land having been broken by the preceding ploughings, was provided with the moiſture neceſſary for plants, from its ſurface to the bottom of the furrows; and the plants were ſenſibly benefited by all our frequent ſtirrings.

" 6. I was ſo ſtruck with this, that I marked ſeveral ſtalks, to ſee how much they grew each day. From the time that the ears began to appear, till they had done bloſſoming, I found that they grew an inch in four and twenty hours. The hotteſt days were thoſe in which the ſtalks grew moſt, whilſt all vegetation ſeemed almoſt ſuſpended in the wheat in the common way.

" 7. This obſervation led me to another. I was greatly ſurpriſed one day to find my ſtalks juſt as I had left them the day before. The next day, and the day after, I found them ſtill the ſame. In ſhort, they grew no longer from that time.

" So ſudden a change raiſed my curioſity greatly, and I reſolved to find out the cauſe of it. The time when they ceaſed to grow, was immediately after they had done bloſſoming. I judged that from that time all the ſap was conveyed to the ear, to form the grains, and that the reſt of the plant had only what was neceſſary to prevent its drying too ſoon. This diſpenſation of the nutritive juices ſeemed to me very remarkable: all their forces ſeem then to unite, in order to form, fill, and ripen the grain, which is the moſt uſeful part. I was afterwards confirmed in this, by obſerving, that it was from that very time that the ſtalks and blades began inſenſibly to loſe their deep green colour, and that this green grew lighter and lighter every day; a ſure ſign of a diminution of ſap in thoſe parts.

" 8. It is likewiſe of very great importance to know, which is the moſt proper time for ſowing; for the growth of plants depends greatly on this circumſtance. Late ſowings have not anſwered; but the early ones have produced plants, whoſe vigour has enabled them the better to reſiſt the winter's cold, and to branch out the more abundantly. By attending to this circumſtance, the farmer will enjoy the deſirable advantage of having his corn ripen early, and of its being leſs expoſed to the dangers of the ſummer ſeaſon; for we have ſeen that the wheat which was ſowed firſt in the new method, ripened thoroughly as ſoon as that which was ſowed in the old way. It is proper to know this, in order to be ſenſible of the neceſſity of beginning to plough early, that the ſeed may be ſowed in due time.

" 9. I muſt beg leave again to make a few reflections relative to the quantity of ſeed moſt proper to be ſown. It is of the utmoſt importance to know how to proportion the quantity of the ſeed to the ſtrength and richneſs of the ſoil, ſo that each may have its due proportion. The experiments already made, help to direct us; but I think others ſtill neceſſary, before we can truſt abſolutely to our knowledge in this point.

" At preſent I ſhall only adviſe ſowing the ſame quantity of ſeed as I did in 1752. I fancy that proportion will not differ greatly from what a longer practice will ſhew to be beſt. However, the ſame quantity of ſeed will not do for every ſoil. It muſt be varied with judgement, and regulated according to the circumſtances of the ſeaſon, and the better or worſe condition of the land. I think, too, that in the firſt, and even the ſecond year of the trials which may be made, it will be proper to ſow a little thicker than I did in 1752. The farmer will eaſily perceive, that when his lands are well looſened and brought to a good tilth, they will require leſs ſeed; but till then, he will do well not to be over ſparing of it.

" 10. We cannot yet determine ſo exactly as we could wiſh, what breadth the beds, including the alleys, ſhould be of, to make the ground produce the greateſt quantity of corn; nor whether it would be beſt to ſow more or leſs than three rows. We confeſs, that we ſhould be glad to ſee a longer ſeries of accurate experiments, and to have a greater knowledge of this matter, before we pretend to fix it. Our beds have always been about ſix feet wide.

" M. Duhamel, who firſt introduced this New Huſbandry in France, intends to make experiments by ſowing only two rows. If they ſhould yield more grain, the breadth of the beds may certainly be diminiſhed: and as it is of conſequence to multiply and vary experiments, in order to determine this point, we now have ſeveral beds ſown, ſome in two, and ſome in three rows. I have likewiſe tried what multiplying the number of rows in ſome fields would do; and the reſult of this experiment promiſes an advantage in that way of ſowing. The ſucceſs of this firſt trial was as follows.

" When the field was ſowed, I obſerved, among the reſt, ten beds which the ploughman had made wider than the others. I was ſorry at firſt, that any part of the ground ſhould be loſt; but, upon ſecond thoughts, I determined to ſow thoſe beds with two turns of the drill-plough; and conſequently to plant them with ſix rows of wheat. I did ſo; and when the firſt ploughing after winter was given,

given, little regard was paid to the two outſide rows, which were torn up by the plough in ſeveral parts; ſo that there remained but four or five rows in thoſe places.

"The wheat of theſe beds, not excepting even the middle rows, grew as high, and branched as much as that of the others, in which there were but three rows. I examined them frequently with great care, and was aſſiſted therein by ſeveral perſons, very capable of judging and making good obſervations. The only difference we could diſtinguiſh, and that was ſcarcely perceptible, was in the ears, which we thought rather ſhorter in the middle rows than in the others; but as there was a greater quantity of them, we judged that theſe beds would yield the moſt grain.

"We were not miſtaken; for their produce was as follows: the ten beds, ſown with ſix rows each, yielded ninety-one pounds of wheat more than ten beds ſown with three rows each. But as this reſult does not ſet the matter in a ſufficiently clear light, we muſt have recourſe to the following calculation. The ſix rowed beds took up more ground than thoſe which had but three rows: two beds more might have been made out of the ſurplus of their breadth; ſo that there would, in that caſe, have been twelve beds inſtead of ten. The queſtion therefore is, whether this ground, made into ten beds, produced more than it would have done if it had been made into twelve beds of three rows each. To which I anſwer, that it did produce thirty-eight pounds more; and that there was likewiſe a ſeventh part more ſtraw.

"As this experiment deſerved to be repeated, I have tried it in a larger way. I have laid ſeveral acres out in beds of about ſeven feet wide: they are ſown with ſix rows: the plants are very fine, and I impatiently wait the event.

"Though I have continued not to dung my fields, the plants ſtill grow very tall, and produce fine long ears, well filled with plump grain.

"I am indebted to the New Huſbandry for the recovery and improvement of worn-out meadows. They have already yielded me plenty of fodder, the value of which ought to be added to the produce of the fields, becauſe the New Huſbandry is the immediate cauſe that manure can be ſpared to enrich thoſe meadows.

General Diſpoſition of the Lands for the Crop of 1754.

"The more I have ſtudied the principles of the New Huſbandry, the more I have been convinced of the advantages attending it. My experiments have not only confirmed me in this opinion; but they have likewiſe ſhewed me, that my practice has been conſiſtent with thoſe principles. This made me determine to lay the whole of one of my farms out in the new way, as ſoon as I poſſibly could; its extent being no more than I can direct almoſt the whole culture of myſelf.

"I have compleated it this year. All the fields, of which only half uſed to be ſowed every year in our old way, are now laid out in beds. I have ſowed them all, with a deſign to continue doing ſo for the future every year. They look exceeding well hitherto: the plants are extremely fine, and promiſe a greater crop next year, than that of the experiments of the foregoing years.

"Theſe experiments have likewiſe made a ſtrong impreſſion on ſeveral perſons in this country, each of whom judged of the New Huſbandry, as his inclination, or proſpect of advantage, directed. It is true, our farmers are more generally inclined to ſow their lands in equally diſtant rows, with the drill-plough, than to lay them out in beds; the proper management of which, ſay they, is attended with much more care and trouble. My drill-plough is preferred on account of its ſimplicity. It began to be uſed laſt year, and numbers of fields near this city (Geneva) have been ſowed with it this year.

"Several of our peaſants have likewiſe tried the drill-plough, and their example will be of conſequence hereafter. Their unwillingneſs to come into any new practice is well known: but this ſeems to get the better of their prejudices; and the proſpect they now have of greater crops than uſual, makes them regret their not having ſowed a larger extent of ground in this manner.

"We have about an hundred and fifty acres ſowed in beds, and alſo near a thouſand ſowed in equally diſtant rows. Such large experiments, and made on different ſoils, cannot but afford new inſtruction: the facts will be better aſcertained, and people will be more thoroughly convinced that the greater product of the crops is owing to the New Huſbandry, and not to favourable circumſtances, to which they are too apt to impute it. Theſe experiments, ſay they, have been made on the very beſt ſoils; it is much eaſier to prepare two or three roods of ground, than an extent of ſeveral acres; theſe little ſpots have been cultivated with vaſt care; it is almoſt impoſſible to beſtow the ſame attention upon large tracts of land.—Luckily, ſeveral lovers of agriculture are making large experiments, which already prove, that the New Huſbandry may eaſily be practiſed in any extent of ground whatever."

CONCLUSION.

"Any one may now judge, by the experiments which have been made theſe laſt four years, and by the ſucceſs which has attended them, how far the principles of the New Huſbandry are juſtly founded, and how far we are in the right road to give ſtill farther demonſtrations of its excellence.

"The lands on which it has been already practiſed, leave no room to doubt that all its operations may be performed with eaſe: and at the ſame time they prove to thoſe who ſhall be inclined to cultivate any part of their farms in the ſame way, that they may do it with equal advantage.

"Convenient inſtruments for executing this culture are already invented and made. The uſe which has been, and ſtill is, made of them, ought to increaſe our confidence in them. It is by their means that the two moſt eſſential articles towards ſecuring ſucceſs, are obtained: the firſt is, the means of forming, ploughing, and cultivating the beds, with great eaſe and little expence: the ſecond, that of ſowing land more regularly, and of giving it the exact quantity of ſeed that may be thought moſt proper, by means of the drill-plough, which buries the ſeed at its proper depth in the furrows, covers it over, and, in ſhort, performs the whole buſineſs of ſowing, with great diſpatch, and a conſiderable ſaving of ſeed.

EXPERIMENTS *made near* Guignes, *in the Province of* Brie, *under the Direction of* M. Rouſſel, *and communicated to* M. Duhamel *in* 1755.

"M. Rouſſel prudently began, as we would adviſe every one to do, with ſmall experiments. His firſt trial of the New Huſbandry was upon a little ſpot: but being prevented from attending to it in perſon, many faults were committed during his abſence. On his return, which

which was towards the end of November 1754, he inquired after his crop, and learnt with pleaſure, that ſome grains had produced upwards of ſixty ears a-piece, and that many of theſe ears contained ſixty-four grains. This was ſufficient to ſhew him the excellence of the new culture, which he immediately determined to extend to larger objects.

He had no time to loſe. Two contiguous pieces of ground, containing twenty-four acres, had been folded, and were juſt going to be ploughed for the laſt time, in order to be ſown according to the uſual practice of the country. Theſe were choſen for the farther trial of the New Huſbandry, and were accordingly ſown with the drill-plough, between the ninth and twenty-firſt of October, with 571 pounds of wheat, including ten pounds and an half, which were uſed to fill up ſome ſpaces where the ſeed had miſſed. This is after the rate of about twenty-four pounds to an acre.

At the ſame time, an adjacent piece of ground, which had been folded like the former, and of which the ſoil was equal to the beſt part of the field ſown in rows, was ſowed in the common way. This laſt contained four acres and a half, and took up 486 pounds of ſeed, which is 108 pounds to an acre.

The corn came up finely in both fields: but that which was ſown in rows happened to be near a wood, from which numbers of rabbits came, and entirely deſtroyed the plants of near five acres: the roots which they left, were eaten up by worms: and the dung of the ſheep-folds produced a great quantity of weeds. This was not all: as the furrows did not run in the direction of the declivity of the ground, the water lodged in them, ſo that the firſt ploughing, which ought to have been given in March, could not be performed till April, when it left a great many clods.

Theſe clods were grown hard by the time of the ſecond ploughing, which was performed with a plough with two mould-boards, which inſtead of breaking and looſening the ground, and laying freſh earth to the roots, only turned thoſe hard clods over upon the rows.

The third ploughing, which was given with a plough with two ſhares, and in more favourable weather, had a better effect.

Notwithſtanding the accidents which had reduced this piece of wheat to ſo wretched a condition, that the huſbandmen ſaid they were ſure it never would produce a crop worth reaping, and that all the labour beſtowed upon it was thrown away; yet, reckoning upon the ſame footing of twenty-four acres, though it would be but juſt to deduct the five which were abſolutely deſtroyed by the rabbits; and ſuppoſing too the crops of 1756 and 1757 to be no greater than that of 1755; M. Rouſſel's calculation proves, that even theſe three crops will ſtill be better than what the ſame field would produce in the common way.

But, ſays M. Rouſſel, if we do the New Huſbandry part of the juſtice it deſerves; and inſtead of including the five acres which the rabbits deſtroyed, we reckon only the produce of nineteen acres prepared in a hurry, and badly ploughed; and even ſuppoſe them to be no better managed in the following years, and the whole extent of the 24 acres, to be only of the ſame quality as the four acres and a half with which it was intended to be compared; the produce of both, in three years, will be as follows.

The nineteen acres produced 11592 pounds of wheat, which was preferred to any other for ſeed, not only becauſe it was finer, but likewiſe becauſe it was quite free from all ſeeds of weeds. This is after the rate of 610 pounds for every acre.

From this, we are to deduct the ſeed, which is, for each acre, twenty-four pounds.

The neat produce of each acre will then be 586 pounds of wheat, free from all ſeeds of weeds.

Suppoſing the crops to be no greater in the following years, though what we ſhall ſay hereafter will ſhew that they certainly will, each acre will have produced neat at the end of three years, 1758 pounds of wheat.

The other piece of ground, which was cultivated in the old way, in order to make the compariſon, produced 1260 pounds an acre, from which we are to deduct 154 pounds for the ſeed.

The remaining neat produce is 1106 pounds.

The ſecond year's produce of this ſame acre, ſowed with ſpring corn, can be reckoned at only half the value of the firſt year's crop of wheat; and the third year produces nothing, being the year of fallow.

Thus the total neat produce of the acre cultivated in the common way will be, at the end of three years, only 1659 pounds; whilſt that in the new way, will be 1758 pounds.

M. Rouſſel *gives the following Account of his Experiments in* 1756, *in a Letter to* M. Duhamel.

"In October 1755, I choſe, in the middle of a fallow field which had been well ploughed, and was not expoſed to any of the accidents I met with laſt year, a piece of ground, which, to make a fair compariſon between the new method and the old, I divided into two equal parts, each containing twelve acres. One of theſe ſpots was ſet apart for the New Huſbandry; and the other, exactly of the ſame quality, and quite contiguous, to be ſowed broadcaſt in the old way.

"This laſt ground had been extremely well dunged by the folding of the ſheep. With regard to the other, which was to be cultivated in the new way, and which compoſed ninety-three beds five feet wide, including the alleys; only eight of theſe beds were dunged by ſheep, and that at the ſame time, and to the ſame degree as the ground by which the compariſon was intended to be made: of the other beds, ſeventy-ſix had no ſort of dung or amendment whatever; and nine were dunged more or leſs, in the manner and proportion hereafter mentioned.

"Moſt of thoſe who practiſe the New Huſbandry uſe no dung at all. I ſuppoſed that their reaſon for rejecting this manure was, the difficulty of finding a proper time to apply it; for whilſt the alleys receive their ſeveral ſtirrings, no wheel-carriage can be admitted with dung without hurting the beds which are ſown, and hardening the looſe mould of the alleys: to carry it on the backs of cattle, would be at beſt a very difficult, tedious, and expenſive way, where any conſiderable ſpace is to be dunged: to ſpread it upon the earth only the moment the ſeed is ſown, is a ſure way to clog up the drill-plough, and hinder its operation, if the dung be not thoroughly rotten; and to breed weeds, which by no means ſuit this culture. To remedy theſe inconveniencies, I contrived the following method. I opened in each of the alleys one of thoſe large furrows which muſt always be every year at the concluding of the ſummer hoeings, in the place where the

three rows of ſeed are afterwards to be ſown; and by drawing the plough with two mould-boards once through it, I made it fourteen or fifteen inches wide; which is the breadth that the three rows of ſeed require. The ſpace between two of theſe deep furrows is exactly the breadth of a cart, the wheels of which going in them, hurt no part that has been ploughed, and do not preſs down or harden the looſe mould; nor do the horſes do any damage, becauſe they neceſſarily tread upon the ſtubble of the late reaped beds, in the middle between theſe two furrows. This was the method I uſed to dung the nine beds, in queſtion. The dung was well rotted: it was ſpread at the bottom of the furrows, and immediately covered over by the ſame ploughing that made the beds which were ſown ſome days after. Perhaps this manure may be of more ſervice to my lands than to many others, becauſe the ſoil is naturally cold and backward. The grain is by this means ſown upon a kind of gentle hot-bed, the warmth of which promotes the branching and vegetation of the plants. The winter rains and froſts raiſe a fermentation. The firſt ſpring ploughing, by giving it a little air, revives that fermentation at the very time when the ſap is moſt active, and the plant begins to branch. As the dung rots, a kind of motion is cauſed in the earth, which in ſome meaſure anſwers the end of a ſlight ploughing, and brings freſh nouriſhment to the roots. The ſame heat as conſumes the ſtraw, likewiſe conſumes the little ſeeds that are in the dung, which might otherwiſe produce numbers of weeds. When this dung is brought up again to the ſurface of the earth, by the next year's ploughings, it will no longer have thoſe hurtful ſeeds. It will indeed have loſt its heat; but it will ſtill have retained all its fatneſs, which will mix with the earth; and land thus conſtantly dunged, will in time become a perfectly fine mould. But if theſe layers of dung ſhould be ſpread too thick, or the dung itſelf be of too hot a nature, the roots of the corn might perhaps be endangered thereby. It was to determine this, that I tried the following experiments, to know the effects of different dungs, and what quantity it is proper to employ.

"Three beds were dunged, in the above manner, with horſe-dung: the firſt, which was 1165 feet long, had three loads of dung; the ſecond, of 1171 feet, had but two and a half; and the third, 1183 feet, had but two. Three other beds were dunged with cow-dung: one of 868 feet, with two loads and a half; and the ſecond of the ſame length, with two loads; and the third, of 874 feet, with only one load and a half. The three remaining beds had ſheep's dung: the firſt, of 842 feet, two loads; the ſecond, of 838 feet, one load and a half; and the third, which was of the ſame length, one load.

"Theſe beds were diſtributed in ſuch manner, that each of them was in the middle of two other beds which were not dunged. The field, thus laid out, was ſown on the thirteenth, fourteenth, fifteenth, and ſixteenth of October, with the drill-plough, which plants three rows in each bed. I uſed 378 pounds of ſeed; and afterwards ten pounds to fill up the chaſms; which is after the rate of thirty-two pounds ſix ounces to an acre, and conſequently a little too much. Accordingly, when the corn came up, I ſaw it was too thick ſown. The reaſon was, that the grain was too ſmall, in proportion to the outlets of the drill-plough. At the end of ten days, this corn roſe well. On the eighteenth of December, I obſerved that moſt of theſe plants had branched into four ſtalks, whilſt thoſe in the common way had but three. I perceived no ſenſible difference then, between the dunged and the undunged beds. It was not till the twenty-fourth of January that I ſaw plainly that the plants of the dunged beds were of a deeper green, and had made longer and more vigorous ſhoots than thoſe of the undunged beds. By the twentieth of February, five ſmaller ſtalks iſſued out of the five great ones, which was not the caſe with the wheat in the common way. The alleys did not receive their firſt ploughing till the 10th of March. Eleven of the main ſtalks grew an inch and an half in five days; and I obſerved that the moles were rather more buſy in the dunged beds, than in the others. As the earth was yet ſomewhat too ſoft, I thought it needleſs to continue a ploughing which could not do any good, and therefore poſtponed it to the twenty-eighth of March, and following days. On the ninth of April, I found a plant with eighteen ſtalks in one of the dunged beds: the greateſt number of branches that any of the plants in the undunged beds had, was twelve: but, on the other hand, I likewiſe found ſome which had eighteen in the field of compariſon ſown in the common way.

"On the ninth of May, this ſame plant had twenty ſtalks; and from that time it branched no more. The ſecond ploughing was not given till three weeks after, viz. the twenty-eighth of May; which, I think, was ſomewhat too late after the corn had ceaſed to branch. By the twenty-third of June, there were three ſorts of wheat to all the beds: there were ears in bloſſom, others juſt going out of bloom, and others not yet out of their hoods. The fineſt ears were thoſe which came up and bloſſomed firſt. The moſt forward beds were thoſe which had been dunged under furrow with ſheep's dung: the next to them were the eight beds which had been folded, the plants of which were a little greener than thoſe of the undunged beds. The laſt ploughing was given on the tenth of July. The grain had then begun to fill: but that in the common way was the moſt forward, though it was ſowed three weeks later than the other. I know not for what reaſon, the wheat of the New Huſbandry began to be reaped on the fourth of Auguſt, and that in the old way was let ſtand till the thirteenth. The produce of both cultures was as follows.

In the twelve Acres cultivated in the new Way, the three Beds dunged with Horſe-Dung, yielded,

	Sheaves.
The firſt, 1165 feet long, dunged with three loads	19

1171 feet long, three 1177 feet, and three 1183, produced in all,	142
This is near 18 ſheaves a-piece.	
The 67 other beds, which had not been dunged, produced in all,	814
This is ſomewhat more than 12 ſheaves a-piece.	
Total produce of the 12 acres cultivated in the new way,	1208
The twelve acres ſown in the common broad caſt way, after having being well folded all over, produced	1820

" Theſe facts ſhew the advantage of dunging in this manner. It is plain that the beſt dung is that of ſheep, and that it is more profitable when laid under furrow, than when it is ſpread upon the ſurface of the ground by folding.

" In proportion to the produce of the bed 842 feet long, which was dunged with two loads of ſheep's dung, and produced ſeventeen ſheaves; the bed 1165 feet long, which was dunged with three loads of horſe-dung, and produced only nineteen ſheaves, would, if dunged with ſheep's dung, have produced $23 + \frac{69}{133}$; and the bed dunged with cow-dung, which yielded but ſixteen ſheaves, would have yielded $17 + \frac{68}{133}$.

" The eight folded beds, whoſe whole length was 9412 feet, would have yielded 190 ſheaves $+ \frac{43}{133}$ inſtead of only 142 ſheaves, which was the amount of their product.

" It is likewiſe plain, that if the whole of my twelve acres in the new way had been dunged with ſheep's dung, as the bed 842 feet long was; I ſhould, in the ſame proportion, have reaped 1700 ſheaves, which would be but 120 ſheaves leſs than the whole produce of the twelve acres folded all over, and ſown in the broad-caſt way. But even then, I ſay, that thoſe 120 ſheaves, would not be equivalent to the quantity of grain which I ſaved by ſowing according to the New Huſbandry. An hundred of our ſheaves yielded, in general, little more than 378 pounds of wheat. The 120 ſheaves which the twelve acres ſown in the broad-caſt way produced more than the twelve acres in beds, would therefore yield but 453 pounds. Deduct this from 871 pounds, which I ſaved in the ſeed of theſe laſt twelve acres ſown in the new way, and I ſhall ſtill be a gainer: for I ſowed only 388 pounds in this ground; whereas 1260 pounds were uſed to ſow the other twelve acres in the common way. This would have been the produce of this firſt year's crop, ſuppoſing that the whole of my twelve acres in beds had been dunged in the ſame manner as the bed 842 feet long. For want of that, I reaped but 1208 ſheaves. They have juſt been threſhed, and have yielded only 5040 pounds of grain."

M. Du Hamel makes the following remarks on this account of M. Rouſſel.

" The 1208 ſheaves yielded but 5040 pounds of grain, from which we are to deduct 388 pounds for the ſeed. The neat produce is therefore 4652 pounds, which would make in three years 13956 pounds. The other field in the common way produced 8757 pounds; from which we are to deduct 1260 pounds for the ſeed: the neat produce is conſequently 7497 pounds; the half of which is 3748 pounds and a half: for the value of the next year's crop. This is all that the twelve acres in the common way would produce in three years, and amounts to no more than 11245 pounds and a half: conſequently the balance in favour of the New Huſbandry in three years, is 2710 pounds and a half, or one fourth part of the whole: and that from a field which was ſown in rows for the firſt time and of which three fourths were not dunged at all: whilſt the other, with which it is compared, had been folded all over, and for the year, produced a very plentiful crop."

Extract of a Letter from a Gentleman in Poitou.

" Being convinced of the advantages of the new method of cultivating land, I reſolved to make a trial of it, by comparing the produce of a field cultivated in the common way, with that of another field cultivated according to the New Huſbandry: and M. Duhamel has deſired all lovers of agriculture to try by experiments made with care, whether it be moſt profitable to ſow beds with two, or with three rows of corn; or, which is the ſame thing, to find at what diſtance the rows ought to be ſown; I divided a ſpot of ground into ten equal parts, which I made into as many beds, each ſix feet wide.

" In the middle of five of theſe beds I ſowed three rows, ſeven inches aſunder; ſo that they took up fourteen inches of ground, and there remained four feet ten inches for the breadth of the alleys, which is very ſufficient for the horſe-hoeing huſbandry.

" I ſowed three other beds with only two rows, a foot diſtant from each other; conſequently the alleys were five feet wide.

" The two remaining beds were ſown with two rows each, three feet aſunder. The alleys were therefore but three feet wide: or rather the whole of this laſt ſpot may be looked upon as ſown in ſingle rows, with alleys three feet wide, which is too narrow a ſpace to admit of horſe-hoeing them conveniently.

" Before I ſpeak of the produce of theſe beds, it will be proper to obſerve:

" 1. That this trial was made with rye. My fear that birds might eat up the wheat, made me prefer rye, which I adviſe every one to do, when only ſmall experiments are made. This eſcaped without the leaſt damage; whereas I have obſerved, that when experiments have been made with wheat, the birds, preferring that to any other grain, have always deſtroyed a conſiderable part of the crop.

" 2. The beds ſown with three rows were near a hedge, which greatly damaged two of them, either by its roots exhauſting the ground, or by its ſhadow keeping that part harder frozen than the reſt.

" 3. The intervals were not hoed at all, between either the double or the triple rows; only the alleys were horſe-hoed; and conſequently none but the ſingle rows were hoed on both ſides.

" 4. On the 25th of February, the alleys were ploughed. I viſited them on the ſecond of March, and found, upon examining the plants, that, in theſe five days, they had ſhot out roots four inches long into the new ſtirred

mould. I repeated the hoeings at proper times, and the rye continued in good condition till it was reaped. The laſt hoeing was given after the bloſſoming was paſt.

" 5. I then examined the roots, and found they had extended eighteen inches into the looſe mould. This may ſeem ſtrange; but I am certain it is true; for I took every precaution not to be deceived.

" 6. The alleys between the ſingle rows were hoed but twice, being too narrow to admit the plough after the plants had begun to branch. However, I had not reaſon to complain of the produce of theſe ſingle rows.

" Having now given an account of my operations, it is time to ſpeak of the products.

" The ears in my rows were from four to ſeven inches long, and the ſtalks from four to ſix feet high, which was one third taller than in the neighbouring fields cultivated in the old way.

" This ſpot of ground, in the beſt years, never produced more than five buſhels, including the buſhel of ſeed corn; for that was the quantity generally uſed: in common years, it has not yielded above four buſhels, and frequently much leſs. We therefore cannot reckon its produce one year with another, at more than four buſhels, including all faulty grains and ſeeds of weeds, which fall through the ſieve, and remain mixed with the good grain. This year it has yielded me ſeven buſhels of fine clean rye, conſiderably larger than the common ſort. I make no account of the ſeed, the quantity was ſo ſmall. To prevent this grain's being mixed with any other, and at the ſame time to judge more exactly of the produce of my ground, I had the ſheaves threſhed out cloſe by the field; but it was in the middle of a road, where all the grains ſcattered by the flail could not be gathered up; by which I reckon I loſt more than the amount of the ſeed that was ſown in the rows. The produce of my little field was therefore this year, compared to other years, as ſeven is to four; to which muſt be added, that it is capable of bearing as great a crop every year, which is not the caſe in the common huſbandry.

" Let us now examine the produce of the rows, and compare them with one another, in order to judge whether it be moſt profitable to ſow in ſingle, double, or triple rows.

" Two beds, the moſt diſtant from the hedge, ſown with triple rows, yielded each three quarters of a buſhel.

Two beds with double rows, yielded each two thirds of a buſhel; conſequently the three beds with double rows yielded two buſhels, and the ſix rows ſown two and two, in three beds, yielded one quarter more than the ſix rows ſown three and three in two rows; but two beds of three rows a-piece yielded one ninth more than two beds of only two rows a-piece; whence we may conclude, that the diſtance of the rows increaſes the produce of an equal number of plants; or, which comes to the ſame, that an equal quantity of ſeed will produce more grain when the rows are more diſtant, than when they are ſown cloſer together. But this is not a real profit; becauſe the ſix double rows take up one third more ground than the ſix triple rows.

" Each of the ſingle rows yielded ſeven-eighths of a buſhel, which is one ſeventh more than the triple rows, though they took up no more ground; and their produce would probably have been greater, if they had been hoed two or three times more.

" It appears by this account, that the profit would probably have been on the ſide of the double rows, if the alleys had been made only four feet wide, inſtead of five; for by this means I ſhould have gained one fifth more ground; and four feet are a ſufficient breadth for the operations of the horſe-hoe. Where the ſingle rows are ſo near as in this experiment, the ſame ground would ſcarcely bear another crop the next year, for want of having been ſufficiently ſtirred. To clear up this point by a new experiment, I have ſown ſingle rows in the middle of four beds, two of which are four feet wide, and the two others only three. The winter hoeings have been given them with eaſe, and I hope the others will not be more difficult, at leaſt till all the corn is ſpindled. What I fear moſt is the earth's being carried off the narrow ſpace on which the rows ſtand, when a thaw comes on, or by the heavy rains which are frequent with us.

" The reſt of my field is ſowed in two rows, in beds four feet two inches wide. I have done this, becauſe, as it is the general cuſtom here to make our ridges about that breadth, I am in hopes that if I obtain a plentiful crop, I ſhall be able the more eaſily to prevail on the farmers of this country to adopt a method, the advantage of which I am ſenſible of, before I tried the above experiments."

As it will doubtleſs be expected by our readers, that the advantages reſulting from both the Old and New Huſbandry ſhould be ſet in the cleareſt and moſt conſpicuous point of light under this article; we ſhall add here two calculations, that lately appeared in the Muſeum Ruſticum, and appear to be made with great accuracy and candor.

The Profit attending Arable and Paſture Land compared, as found by Experience, near Bury, in Suffolk.

The following calculation of the different profit attending arable and paſture land in my neighbourhood, is drawn up not merely from fancy, but from the exact accounts I have kept of my own crops, and the information I have gained from ſeveral ſenſible farmers.

I take twenty acres, and ſuppoſe them an addition to a farm; but I ſhould premiſe ſuch an one as will require ſome additional cattle to be kept for it, perhaps two horſes; but a farm of fifty pounds per annum may be ſo circumſtanced as to require no material ſtanding expences extraordinary for ſuch an addition, in which caſe the ploughings, &c. will not coſt near what I have laid them at; but the faireſt way is the ſuppoſition I have made. We reckon nothing is either got or loſt by four ſhillings per acre for a clean earth.

Calculation of the Expences and Profit of farming a ploughed or paſture Field of twenty Acres for nine Years, on a Suppoſition that it is not a Farm by itſelf, but an Addition to another of fifty Pounds per Annum, the Soil wet, and a looſe Woodcock, Brick Earth, on the Surface, for eighteen Inches deep, and under that a very good ſtiff Clay, improved by Land-draining.

Total profit in nine years;

Which is fifteen pounds fourteen shillings and eight-pence per annum, or rather better than fifteen shillings per acre.

But I should observe, that as a crop of clover-seed is the most uncertain and various of any that is grown, I have reckoned less for it by far than multitudes produce, though, at the same time, many bring nothing at all.

I know a field of twenty acres, which I have been often told by several who knew the crop, once produced the farmer five bushels per acre. It was all down on a Friday, and the farmer suspecting a change of weather, by great rewards to his workmen, and bringing casks of ale into the field, and feeding them well, tempted them to work in an extraordinary manner all the Saturday, and cleared the whole into barn. It began raining in the night, and so much succeeding bad weather came, that the crops were, in general, greatly damaged. His produced, as I said, one hundred bushels, all which he sold at three pounds ten shillings per bushel, arising to three hundred and fifty pounds. And a few years ago I saw the same field with a crop of clover, which did not produce twenty pecks, and that so wretched as to fetch nothing.

I read

I read this calculation to a farmer, and he obſerved, that I ſhould reckon eighty buſhels for the crop; and as it is often grown, I will give you another total, with that alteration, that your readers may adopt either, according to their idea of the chance.

	l.	s.	d.
Profit	248	13	9
Loſs	56	16	0
	191	17	9

which is twenty-one pounds ſix-ſhillings and five-pence per annum, or better than a guinea per acre.

As I mention back-carriage in this calculation, I will explain my meaning. We generally carry our corn to Ipſwich, Manningtree, or Thetford, from which places we load home with coals for blackſmiths, or any perſons that want them, who pay us eighteen ſhillings for the carriage of a loading, twelve ſhillings per chaldron, and we generally bring one and a half. But as we may accidentally carry our corn where none is to be had, I make ſuch allowance as to bring it near the truth.

Calculation of nine Years Expences and Profit of twenty Acres of Graſs-Land, the Soil ſuppoſed to be the ſame as the above Arable-Land, with no other Difference than being Graſs or Ploughed.

Which

Which is twenty-three pounds eleven ſhillings and two-pence per annum, or one pound three ſhillings per acre profit.

The above account diſplays the vaſtly ſuperior advantages of graſs, with us, to arable land.

You will certainly remark, that nothing in the above account is reckoned for loſſes of ſtock; but in anſwer to that I ſhould obſerve, that nothing is calculated in the arable account for ſome bad years, when in ſuch land not a quarter of a crop is produced: and I do not mean this calculation as perfect (that is impoſſible) but only to diſcover the proportion between the one method and the other; and from what I have obſerved, and gathered from the information which the moſt intelligent farmers can give me, I am clear of opinion, that the chances, on the whole, are much in favour of the graſs-land, the crop of hay and ſeed being much more regular than thoſe of corn, clover, or turnips; and ſuppoſing the eighty buſhels of clover-ſeed, yet the graſs profit far exceeds the arable, even then; but, as I obſerved, the probability lies againſt the latter, ſuppoſing the profit to be only fifteen pounds fourteen ſhillings and eight-pence per annum.

I may remind you, that I ſuppoſed this twenty acres to be an addition to a farm, not one by itſelf, and ſo compared the reſpective profits; therefore I have not allowed any thing for the feed which the above-mentioned cattle may accidentally have on the arable land, or turnips which they may expend in the winter; and for this reaſon, becauſe, although it appears to me that graſs is the moſt profitable huſbandry, yet a certain quantity of ploughed land ſhould undoubtedly be a part of every graſs-farm, for the raiſing turnips, ſome artificial graſs, and ſtover enough for the winter's food.

I hope your readers will peruſe this calculation with candour, and believe me, when I aſſure them it is the neareſt truth of any I can make, either from my own experience, or beſt information. *Muſeum Ruſticum, vol.* III. *p.* 317.

State of the Expence of a hoed Crop of Wheat, and the Profit of it, compared with that of the common Huſbandry.

I propoſe here to ſtate the expence of a hoed wheat-crop. If this is done in any place where the price of labour is known, it will be eaſy from thence to calculate the expence of ſuch crops in any other places.

When wheat is to be horſe-hoed, it is planted upon three-bout ridges, about four feet and eight or nine inches broad. If the ſoil is poor, they may be made broader, but ſhould not be much narrower, otherwiſe there will not be room enough to plough the intervals. Two rows of wheat, about ten inches aſunder, are drilled upon the top of each ridge, and then the intervals or ſpaces between the double rows will be about three feet and ten inches wide.

For the firſt crop the land ſhould be well prepared, and very clean: it will therefore coſt more than the following crops; and if the land is not in good heart, the firſt crops will be the ſmalleſt, for hoeing greatly improves it. The following eſtimate is of the ſucceeding crops.

The neceſſary culture for theſe is, once ploughing in autumn, to form the new ridges for the next crop. This may be done with three horſes; for the intervals, by frequent hoeing, are kept in fine tilth, and are ploughed at one bout; and the middle of the ridges where the laſt crop ſtood, being only the breadth of two narrow furrows, are eaſily ploughed at another bout; ſo that theſe ridges, which in common ploughing required three bouts with four horſes, are now ploughed at two with three horſes.

The intervals, after the corn is planted, are hoe-ploughed at one bout, to or from the rows. They are uſually thus ploughed four times, once in the beginning of winter, and three times afterwards in the ſpring and ſummer.

The ten inch partitions, or ſpaces, between the rows of wheat, are hand-hoed about the end of March: once is generally ſufficient, becauſe the wheat ſoon afterwards ſpreads, covers the partitions, and keeps down the weeds. The rows are alſo to be weeded. This is all the ploughing and hoeing that is commonly neceſſary till harveſt. But as in ſome years it may be proper to plough the ridges in autumn at five or ſix furrows, or plough them twice, ſometimes to hoe-plough the intervals more than four times, or to give them a trench-ploughing, where the ſtaple is deep enough to admit of it, I ſhall make a full allowance for theſe, and charge two ploughings and ſix horſe-hoeings every year.

The hiring price in ſome parts of Middleſex for ploughing a ſtrong loam the firſt time, in the common way, is ſeven or eight ſhilling an acre; I ſhall ſay eight ſhillings. They work about eight hours, and plough about an acre a day with four horſes. The price of the labour may be thus diſtinguiſhed: to the ploughman twenty-pence, and boy eight-pence a day, including their beer; and then the horſes and harneſs, &c. will come to ſeventeen-pence a day each. Twice ploughing therefore in autumn, with three horſes, comes to eight ſhillings and nine-pence.

The tops of the ridges are to be rolled with a light roller, or harrowed once or twice with two very light harrows, to break the clods, and lay the tops of the ridges ſmooth for drilling. The harrows are faſtened together by a pole; and a horſe, walking in the furrow, draws the two harrows, one upon each ridge. A rolling in the ſame manner is alſo uſeful in the ſpring, when the earth is pretty dry, and before the partitions are hand-hoed. Theſe rollings and harrowings, of two ridges at once by one horſe, are done at a ſmall expence; and not being neceſſary every year, may coſt about four-pence: but to make the total an even ſum, I ſhall charge for them (and uncovering the plants, if any clods happen to fall upon them at the firſt hoe-ploughing) ſeven-pence half-penny per acre.

The uſual quantity of ſeed is three pecks, and if it coſts five ſhillings and ſix-pence per buſhel, is four ſhillings and three half-pence per acre. The drilling is performed by a man and a boy, and one horſe. They may drill ſix acres a day: I ſhall ſay but five, which is nine-pence per acre.

The intervals ſhould be kept in fine tilth: they are hoe-ploughed at one bout: three horſes are ſufficient for the firſt two hoeings, and two for the reſt. I ſhall reckon three for each hoeing, and then ſix hoeings come to thirteen ſhillings and two-pence.

The price for hand-hoeing of beans the firſt time is about five ſhillings per acre; I ſhall call it ſix; and as the ten inch partitions, and about two inches on each outſide of the rows, is the whole to be hand-hoed (for the hoe-plough does the reſt) theſe are about one fourth part of the ridge, and ſhould be done for eighteen-pence an acre:

but it is a good way to agree with the hoers to cleanſe the rows alſo of weeds; and as theſe ought to be well done, they expect ſomething more than for common work, and they will coſt near half a crown per acre.

For reaping the prices are various; from five or ſix, to ten ſhillings per acre; at a medium, eight ſhillings is a high price. The drilled wheat, having ſcarcely any weeds in it, and ſtanding upon only about a fourth part of the ridge, is eaſier and much quicker reaped than ſown wheat, and not really worth above half the common price; but, for the above reaſon, I ſhall allow, for reaping and carrying ſix ſhillings per acre.

Wheat-ſtraw is a valuable article in the neighbourhood of London; and the ſtraw, chaff, &c. might be reckoned here to pay for threſhing and carrying the corn to market: where it is otherwiſe, an allowance is to be made. And as the diſtance from the market is uncertain, I ſhall charge the carrying out, and at market, a ſhilling per quarter, beſides the value of the ſtraw.

Some eſtates are tythe-free; others pay in kind, or a modus. I ſhall reckon the tythe at four ſhillings per acre.

Suppoſe the rent is ſixteen ſhillings per acre, there remain to be added the taxes, or rates payable by the tenant, which, at two ſhillings in the pound-rent, come to nineteen-pence per acre.

I reckon nothing for dung or manure; for land that is proper for wheat, allowing ſufficient intervals and hoeing, requires none. If the wheat of the firſt crops is weak in the ſpring, a top-dreſſing of the rows will be of ſervice, or afterwards, if the proper hoeings have not been given the preceding year; but this ſeldom happens; for hoeing makes the plants ſtrong, and if then alſo top-dreſſed, they would be in danger of lodging.

The whole expence, at theſe prices, of horſe-hoed wheat, is, per acre, as follows:

	l.	s.	d.
Two ploughings in autumn, with three horſes	0	8	9
Harrowing, ſeed, and drilling - -	0	5	6
Six hoe-ploughings of the intervals, with three horſes - - - -	0	13	2
Hand-hoeing, weeding, and harveſting	0	8	6
Carrying out twenty buſhels, and at market, (beſides the value of the ſtraw and chaff) at one ſhilling per quarter - -	0	2	6
Tythe, rent, and taxes - - -	1	1	7
	3	0	0

This is the whole expence, ſuppoſing the ſoil to be a ſtrong loam, the wages high, and the horſes hired; but when done by the farmer's own horſes, or the ſoil lighter, and they work more hours in a day, the expence will be a great deal leſs, as we ſhall ſee below: in ſome places it will not much exceed half this ſum.

It has been already ſhewn, that one hundred acres of horſe-hoed wheat, much of it a light, poor ſoil, produced near twenty buſhels per acre; and that a ſtrong ſoil, by a medium of twenty hoed crops, produced about twenty-four buſhels per acre, both nine-gallon meaſure; and therefore we might reckon here a middling crop about twenty-four buſhels: but to avoid all ſuſpicion of partiality, I ſhall ſuppoſe, that a good loam may, one year with another, produce only the leaſt of theſe, or twenty buſhels per acre.

The mean price of wheat at Windſor market, for the laſt twenty years, ending at Michaelmas, 1762, is nearly four ſhillings and eight-pence three-farthings per buſhel, and twenty buſhels, at this rate, come to four pounds fourteen ſhillings and ſeven-pence: ſo the profit of the horſe-hoed wheat is one pound fourteen ſhillings and ſeven-pence per acre, or above two rents.

Your ingenious correſpondent has above ſtated the produce and expence of twenty acres of arable land for nine years, according to the courſe of huſbandry practiſed in his neighbourhood, I ſhall, by way of compariſon, calculate the profit of theſe twenty acres, ſuppoſing they had been under crops of hoed wheat during theſe nine years.

I reckon, from your corroſpondent's account, the wages of his ploughmen to be about fourteen-pence, and a boy four-pence a day (if not allowed beer) and the horſes a ſhilling a day each; in all, five ſhillings and ſix-pence, beſides repairs: and if they work more than eight hours, his land being lighter than the above, they may plough about an acre and a half a day, which brings the price for ploughing to near his reckoning of four ſhillings per acre. If this is not exact, he will rectify it. I ſhall ſtate the ploughings and horſe-hoeings, in this proportion, and allow three horſes, though fewer will do in this land. The rent-charges, I ſuppoſe, include the tenant's taxes; if not, they are to be added to the expence. As the tythe is not mentioned in his account, I do not charge it here. The other items are computed in proportion to his, and the above, ſtate of the expence; and as I abated four buſhels in the above crop per acre, I ſhall do the ſame here, and reckon a middling crop of hoed wheat at only eighteen buſhels; his producing, by a medium of three crops, twenty-two buſhels and two fifths per acre. The expence of a horſe-hoed acre of this land will be nearly as follows:

	l.	s.	d.
Twice ploughing in autumn, with three horſes, and harrowing - - - -	0	3	$0\frac{1}{2}$
Seed three pecks (fifteen ſhillings and four-pence per coomb at a medium) and drilling five acres a day - - - -	0	3	$4\frac{1}{2}$
Six hoe-ploughings, with three horſes	0	4	0
Hand-hoeing (at four ſhillings per acre, reckoned for turnips in the account) and weeding - - - - -	0	1	8
Harveſting, three ſhillings and nine-pence: thrething four coomb and a half, four ſhilings and ten-pence - -	0	8	7
Carrying out four coomb and a half, and at market - - - -	0	4	$1\frac{1}{2}$
Rent-charges - - -	0	15	0
Total expence per acre	1	19	$9\frac{1}{2}$
The three crops of wheat were ſold, at a medium, for fourteen ſhillings and five-pence and four ſevenths per coomb, which, for eighteen buſhels, comes to -	3	5	$0\frac{1}{2}$
Profit per acre	1	5	3

The

HUS

			l.	s.	d.
The twenty acres, in nine years, produced ſeven crops, valued at five hundred and three pounds; but in the ninth year, the crop of ſixty coomb is caſt by miſtake at eighty-ſeven pounds, which ſhould be but half that ſum deducting therefore forty-three pounds ten ſhillings, the produce amounts to			459	10	0
The expence of theſe twenty acres in nine years, as charged - - -	361	10 3	381	10	3
To which is to be added for four hundred loads of dung	20	0 0			
Remains the profit in nine years			77	19	9
Which is, per acre per annum, near			0	8	8

There were eight hundred loads of dung laid upon theſe twenty acres; but it is hardly to be ſuppoſed, that half that quantity could be made from the ſeven crops; ſo that at leaſt four hundred loads muſt be had elſewhere; and the dung is at a high price in that neighbourhood. I have charged but a ſhilling a load for it.

But if it ſhould be ſuppoſed, that more than four hundred loads could be made from theſe ſeven crops, it muſt alſo be admitted, that a quantity in proportion would be made from the nine crops of wheat, which not being neceſſary in the hoeing culture, is worth, to be ſold, more per load than I have reckoned above; and the value of it ſhould then be added to the profit of the hoed crops.

Let us next compare the whole profit of theſe twenty acres in nine years, in both theſe methods of huſbandry.

	l.	s.	d.
The profit, in nine years, of the hoed crops, amounts to - - -	227	5	9
The profit in that time by the common huſbandry - - - - -	77	19	9
Balance in favour of the New Huſbandry	149	5	3

Hence appears the great ſuperiority of the hoeing culture; and even allowing the clover had produced four buſhels of ſeed per acre, the New Huſbandry is ſtill by far the moſt profitable.

J.

JAU

JACK, an inſtrument for turning the ſpit; alſo a contrivance for ſupplying the place of a boy in pulling boots off. It alſo ſignifies a ſupport for ſawing wood upon.

JAMOCK, or *jannock*, oaten bread made into large loaves.

JARDON, a name given by farriers to a ſwelling on the out-ſide of the back of a horſe.

It generally proceeds from blows and kicks of other horſes; but frequently happens to managed horſes, by ſetting them on their haunches: it is ſeldom attended with much lameneſs, unleſs it has been neglected, or ſome little proceſs of the bone broken. It ſhould be firſt treated with coolers and repellents, ſuch as hot vinegar, verjuice, &c. but if any ſwelling continues hard and inſenſible, the beſt way is to bliſter or fire; but mild bliſters alone generally ſucceed. *Bartlet's Farriery, page* 263.

JAUNDICE, a diſtemper incident to horſes, and generally called, by farriers, the yellows.

Horſes are frequently ſubject to this diſtemper, which is known by a duſky yellowneſs of the eyes; the inſide of the mouth and lips, the tongue and bars of the roof of the mouth looking alſo yellow. The creature is dull, and refuſes all manner of food; the fever is ſlow, yet both that and the yellowneſs increaſe together. The dung is often hard and dry, of a pale yellow, or light pale green. His urine is commonly of a dark dirty brown colour; and, when it has ſettled ſome time on the pavement, it looks red like blood. He ſtales with ſome pain and difficulty, and if the diſtemper is not checked, ſoon grows delirious and frantic. The off-ſide of the belly is ſometimes hard and diſtended; and in old horſes, when the liver has been long diſeaſed, the cure is ſcarce practicable, and ends fatally with a waſting diarrhæa: but when the diſtemper is recent, and in young horſes, there is no fear of a recovery, if the following directions are obſerved.

Firſt of all, bleed plentifully; and give the laxative clyſter, as horſes are apt to be very coſtive in this diſtemper; and the next day give him this purge.

Take of Indian rhubarb, powdered, one ounce and a half; ſaffron two drams, ſuccotrine aloes ſix drams, ſyrup of buckthorn a ſufficient quantity.

If the rhubarb ſhould be found too expenſive, omit it, and add the ſame quantity of cream of tartar, and half an ounce of Caſtile ſoap, with four drams more of aloes. This may be repeated two or three times, giving intermediately the following balls and drink.

INC

Take of Æthiops mineral half an ounce; millepedes the ſame quantity, Caſtile ſoap one ounce; make into a ball, and give one every day, and waſh it down with a pint of this decoction.

Take madder root and turmerick, of each four ounces; burdock root ſliced, half a pound; Monk's rhubarb four ounces; liquorice ſliced two ounces: boil in a gallon of forge water to three quarts; ſtrain off, and ſweeten with honey.

Balls of Caſtile ſoap and turmerick may be given alſo for this purpoſe, to the quantity of three or four ounces a day, and will in moſt recent caſes ſucceed.

By theſe means the diſtemper generally abates in a week, which may be diſcovered by an alteration in the horſe's eyes and mouth; but the medicines muſt be continued till the yellowneſs is intirely removed. Should the diſtemper prove obſtinate, and not ſubmit to this treatment, you muſt try more potent remedies, viz. mercurial phyſic, repeated two or three times at proper intervals; and then the following balls:

Take ſalt of tartar two ounces, cinnabar of antimony four ounces, live millipedes and filings of ſteel, of each four ounces, Caſtile or Venice ſoap half a pound: make into balls of the ſize of pullets eggs, and give one night and morning, with a pint of the above drink.

It will be proper, on his recovery, to give him two or three mild purges, and, if a full fat horſe, to put in a rowel. *Bartlet's Farriery, page* 156.

ILES, or *oiles*, the beards or the ears of barley, wheat, &c.

INCLOSURE, the ſeparation of common grounds into diſtinct poſſeſſions.

The incloſing lands, and dividing them into different fields, paſtures, &c. is a moſt eſſential part of their real improvement, and attended with many very conſiderable advantages, of which we ſhall here mention only the following:

Incloſures aſcertain to every man his juſt and due property, and thereby prevent infinity of treſpaſſes, injuries, and other ſources of ruinous litigation. They keep the land warm, and add to its fertility, by ſcreening it from violent and nipping winds, which otherwiſe frequently deſtroy whole crops; and they alſo defend it from thoſe drying and ſcorching winds, which ſo often blaſt at once the huſbandman's, till then well grounded, expectations. They afford ſhade in the ſummer, and ſhelter in the winter, for cattle, which would otherwiſe deſtroy more with their feet than they eat with their mouths, and which

which, for want of theſe might, as Mr. Worlidge obſerves, loſe more of their fat or fleſh in one ſultry day, than they gain in three cold ones. Their cuttings afford fuel to the induſtrious huſbandman, and, if carefully planted and preſerved, they will here and there furniſh him with timber for his carts, ploughs, and other utenſils, beſides ſometimes uſeful fruits. They are an excellent encouragement to good huſbandry, and a great remedy againſt beggary, by employing many poor people in the labour which either the making, or the mending of them conſtantly requires, and which is amply repaid by the increaſe of crops: for it has been remarked, not only that well incloſed countries generally maintain treble the number of inhabitants, or more, than the champaign; but alſo, that thoſe inhabitants are much better fed and clad, than the common run of people in unincloſed lands. To be convinced of this, let any one but examine our vaſt downs, commons, heaths, waſtes, and unimproved foreſts, badges yet remaining, as Mr. Worlidge properly terms them, of poverty and idleneſs; but at the ſame time, thoroughly ſuſceptible of being converted, with proper care, into corn and paſture fields, meadows, gardens, orchards, and pleaſant groves, the marks of induſtry and good huſbandry. Let him but compare the naked parts of Wiltſhire, Glouceſterſhire, Hampſhire, Surry, &c. with the delightful parts of Kent, Hereſordſhire, and other counties, and he cannot but be ſtruck with a demonſtration of the immenſely valuable improvements which may yet be made in very many parts of this kingdom. The now unimproved, un-occupied crown-lands, might alone, or even only a part of them, be rendered an inexhauſtible ſource of unequalled wealth to the ſovereign, of a vaſt increaſe of his ſubjects, and of happineſs to all.

The common objection againſt incloſures have been ſo well refuted by many very able writers, and are daily invalidated by that moſt unerring teſt, experience, that it would be needleſs for us to recapitulate them here: we therefore ſhall only point out one farther eſſential advantage attending this great improvement, which is, that it enables the farmer to act as is moſt agreeable to him in ſowing when, and what, he pleaſes.

Every gentleman, whoſe eſtate is not yet incloſed, and who is conſequently at liberty to chooſe the manner and means of doing it, will rationally begin with having a map of it drawn, that he may thereby be enabled to divide and portion it out, with the greater propriety and preciſion, ſo as to render it moſt pleaſing to the eye, and moſt convenient to each farmer. If he has a place of reſidence upon it, he may make the whole become ornamental to that reſidence, by a judicious diſpoſition of his hedges and plantations, as has been nobly done at Boughton, in Northamptonſhire, by the late duke of Montague, who, with a moſt refined taſte, and truly benevolent mind, diſdaining all the little and confined ornaments of a park, executed his fine improvements there in ſuch a manner, as to render them pleaſingly beneficial to all his neighbours, as well as to every perſon ſettled upon his land. Gubbins, in Hertfordſhire, the ſeat of Sir Jeremy Sambrook, is another charming example of elegance, though leſs extenſive than the former.

Ha-ha walls, and pieces of water, with rails running acroſs them, are an eaſy means of preſerving a fenced level.

The farms ſhould be ſo divided, that the dwelling of each tenant may be as contiguous to his land as conveniency will admit of, to prevent length of carriage, and to facilitate his due attendance.

Small farms have always been obſerved to yield the greateſt proportional rent, and ſmall incloſures conſtantly produce the moſt plentiful crops.

Incloſures for arable lands ſhould be larger than for paſtures, that the ſoil may be kept dry, and the corn be well aired. For the manner of making incloſures, *ſee the article* FENCE.

ING, a common paſture or meadow.

INOCULATION, a very curious operation in gardening, otherwiſe called budding.

It is a kind of grafting practiſed in the ſummer months on ſeveral kinds of ſtone fruits, as peaches, nectarines, cherries, plums, apricots, &c. alſo upon oranges, jaſmines, and various other ſorts of plants, which ſucceed better by this practice, than by the common method of grafting. The operation is performed in the following manner:

Being provided with a ſharp knife, with a flat haft, made for this purpoſe, as alſo with the cuttings of the tree intended to be propagated, make choice of a ſmooth part of the ſtock intended to be inoculated; if deſigned to be dwarf, five or ſix inches from the ground: but if a ſtandard, it ſhould be budded at the height of five and a half, or ſix feet; then, with your knife, make an horizontal cut acroſs the rind of the ſtock, and from the middle of that cut make a ſlit downwards about two inches in length, being careful not to cut deeper than the thickneſs of the bark, leſt the ſtock is wounded; then having the cutting ready, cut off the leaf from the bud, leaving the foot-ſtalk remaining; cut the bud off lengthways, ſomewhat longer than the ſlit in the ſtock, with part of the wood to it; this done, with your knife ſlip the wood from the bark with a ſudden jerk, and obſerve whether the eye of the bud is left or not, for thoſe buds which loſe their eyes in ſtripping are uſeleſs; then with the handle of the knife gently raiſe the bark on each ſide of the ſlit in the ſtock, and inſert the bud therein, obſerving to place it ſmooth between the rind and wood of the ſtock, cutting off that part of the rind of the bud which may happen to be too long for the ſlit made in the ſtock; ſo having exactly fitted the bud to the ſtock, tie them cloſely round with wetted ſtrong baſs, taking care not to bind round the eye of the bud, which ſhould be left open. In about three weeks or a month, the buds will require to be looſened of the bandage, which, if not done in time, will be very injurious to them, but not to be entirely diveſted of the binding, as it is not amiſs to ſlightly tie them again, which will prevent the bark of the ſtock from flying open, as ſometimes happens, whereby the bud is much injured, if not entirely deſtroyed.

The March following, the ſtock ſhould be cut off about three inches above the place of inoculation, ſloping it the contrary way to the bud; this length is of uſe to faſten the ſhoot which proceeds from the bud, which otherwiſe might be blown out by ſtrong winds; but the autumn following, it ſhould be cut cloſe juſt above the bud, that the place of amputation may the more readily be barked over.

The time for inoculation, is from the middle of June to the latter end of Auguſt, according to the ſeaſon and the forwardneſs of the different ſorts of trees intended to be budded, which muſt be known by trying if the buds will

ſeparate

ſeparate from the wood eaſily. The firſt ſort of fruit commonly inoculated, is the apricot, and the laſt the orange; although the orange is commonly budded in Auguſt, it is very proper to try the operation in July, and thoſe ſtocks which miſcarry may be budded the ſucceeding month, or even in September; but let it be done when it will, it is proper to place them in a gentle heat, giving them plenty of water, by which means there will be no reaſon to doubt of their ſucceſs.

In performing this operation, it will be neceſſary to take the opportunity of moiſt cloudy weather, as the bud and ſtock will more readily unite, being more replete with juices than in hot dry weather, when the ſtock will perſpire ſo faſt, as to leave the buds deſtitute of moiſture.

INOM, or *Innum barley*, ſuch barley as is ſown the ſecond crop after the ground is fallowed.

INSECT, a general name for the ſmaller kinds of animals.

With regard to the generation of inſects, the world is now in general convinced, that they are not bred from corruption, but from eggs, though the contrary was believed by the ancients.

Malpighi, Swammerdam, and Redi, have abundantly confuted the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly, and have ſhewn, that all the members of the butterfly were incloſed under the nympha or ſkin of the caterpillar, as the parts of a plant are in the ſeed.

Inſects take particular care to depoſit their eggs or ſemen in ſuch places where they may have a ſufficient incubation, and where the young, when hatched, may have proper food till they can ſhift for themſelves. Thoſe whoſe food is in the water, lays their eggs there; thoſe to whom fleſh is a proper food, in fleſh; and thoſe to whom the fruits or leaves of vegetables are food, are accordingly depoſited there, but conſtantly the ſame kind in the ſame tree. As for others that require a greater degree of warmth, they are provided by the parent with ſome place in or about the body of other animals, as the feathers of birds, hair of beaſts, ſcales of fiſh, in the noſe, in the fleſh, nay ſome in the bowels of man, and other creatures. As for others, they make them neſts, by digging into the earth, wood, &c. carrying in and ſealing up proviſions that ſerve for the production of their young, and for their food when produced.

There is obſerved in flies, butterflies, &c. a kind of glue, by which the female faſtens her eggs to the bearing buds of trees, &c. ſo as not to be hurt by rain or froſt.

Mr. Andry, in his Treatiſe *De la Generation des vers dans le Corps de l'Homme*, takes notice, that the ancients were miſtaken in denying that inſects breathed, on account of their wanting lungs; for modern obſervations convince us, that inſects have a greater number of lungs than any other animals. They alſo thought that they had no blood, as many of them had no red liquor like ours; but it is not the colour, but the uſe of the liquor, that is to be regarded. They alſo believed that they had no hearts; whereas our microſcopes now diſcover that, when inſects have ſeveral lungs, they have alſo ſeveral hearts; and this in particular is obſervable in ſilk-worms, who have a continued chain of hearts from the head almoſt to the extremity of the tail; and, as is apparent from ſeveral inſects, who give ſigns of life, long after they are divided into ſeveral parts.

Inſects want no parts that are either neceſſary or convenient for their uſe, or to render them complete in their kind. Some affirm that earth-worms, and thoſe round-tailed worms, which are found in the inteſtines of men, horſes, &c. as alſo ſnails and horſe-leeches, are hermaphrodites; but that ſuch worms as become flies, and that ſilk-worms, are not ſo, being of no ſex, but neſts full of real animals, which in time come out with wings.

Several ſorts of inſects do irreparable injury to the huſbandman, tho' ſo very minute as hardly to be diſcovered.

Among others, a ſmall kind of worm gets into the roots, chiefly of oats, and, working upwards, deſtroys all the inſide of the plant, which periſhes ſoon after. M. Duhamel ſuſpects it to have been an inſect of this kind that deſtroyed vaſt quantities of wheat in the neighbourhood of Geneva, and of which M. de Chateauvieux ſent him the following account. "Our wheat, ſays that illuſtrious huſbandman, in the month of May 1755, ſuſtained a loſs which even that cultivated according to the New Huſbandry did not eſcape. We found in it many little white worms, which afterwards became of a cheſnut colour. They poſt themſelves between the blades, and eat the ſtems. They are uſually found between the firſt joint and the roots. Every ſtalk which they attacked, grew no more, but became yellow and withered. The ſame misfortune befel us in the year 1732. Theſe inſects appeared about the middle of May, and made ſuch havock that the crop was almoſt deſtroyed."

Mr. Liſle mentions, that on the 13th and 14th of June, in pulling up wheat in ear, and ſow-thiſtles, he obſerved among the upper part of the roots of moſt of theſe plants, knots or cluſters of graſs-lice, or green locuſts, as he calls them, which appeared whitiſh when they were but juſt come to their ſhape, and as yet under ground; and among moſt of theſe cluſters he obſerved a fly at her incubation, very turgid, of a whitiſh matter; ſhe being then blowing theſe inſects. Her wings were black, and he thought her plainly the ſame as the locuſt, excepting that it had wings. He did not find more than one fly at any one root.

We too often find, in our kitchen-gardens, a ſort of vermin called vine-fretters. They fix upon the roots of leguminous plants, which afterwards gradually turn yellow, and die. M. Tillet ſays he has obſerved the ſame inſect in the roots of wheat.

The cuckow-ſpit, or ſpring-forth, as it is commonly termed, lodges itſelf principally in the joints of plants, ſeldom appears before the latter end of May, and is moſt common when rain has fallen after a ſeries of dry weather. M. Poupart, in his account of this little creature, ſays, that as ſoon as it is out of its egg, it goes to a plant, which it touches with its fundament, and faſtens there a white drop of liquor full of air; that it drops a ſecond near the firſt, then a third, and ſo on till it covers itſelf all over with a ſcum or froth, which keeps it from the heat of the ſun, or ſpiders that would ſuck it. But Mr. Liſle takes this liquid to be nothing but the nightly dew, which falls on the fork or joint of the plant, where the little inſect works it into froth with its proboſcis, as with a bellows. *See the article* BUTTERFLY.

INSTEP, a name given to that part of a horſe's leg, which reaches from the ham to the paſtern-joint.

INUNDATION, a flood, or the overflowing of lands by a large collection of water. For the manner of guarding againſt the bad effects of inundations, *ſee the article* BANKS.

JUG, a large drinking veſſel, with a gibbous or ſwelling belly.

JUNET, earth-nut.

K.

KID

KEEVE, a fat in which beer is worked or fermented.

KELL, a web, or kind of bag, in which inſects are bred.

KID, a ſmall faggot of under or bruſh-wood.

KIDEROW, a place for keeping a ſucking calf.

KIDNEYS, two pretty large glandulous bodies ſituated in the cavity of a horſe's loins upon the two lowermoſt ribs.

Their uſe is to ſeparate the urine, which is of great importance to the health and preſervation of horſes, they being liable to many diſeaſes, which either take their origin from faulty kidneys, or have at leaſt ſuch ſymptoms, as plainly ſhew the kidneys to be more or leſs affected.

The ſigns of the kidneys being hurt or affected, are a weakneſs of the back and loins, difficulty of ſtaling, faintneſs, loſs of appetite, and deadneſs in the eyes; the urine is thick, foul, and ſometimes bloody, eſpecially after a violent ſtrain. A horſe diſeaſed in his kidneys can ſeldom back, that is, move ſtrait backwards, without pain, which is viſible as often as he is put to the trial: the ſame thing is obſervable indeed in horſes, whoſe backs have been wrang and wrenched, but with this difference, that in the latter there is ſeldom any defect or alteration in the urine, except that it is higher coloured.

Bleeding is the prime remedy, and that plentifully, in order to prevent inflammation; and the more ſo, if a fever attends a difficulty in ſtaling, for then we may ſuſpect the kidneys already inflamed. A rowel in the belly has been found uſeful, and the following balls may be given twice or thrice a day, with a pint of marſhmallow decoction, in which half an ounce of gum-arabic is diſſolved, with an ounce of honey.

Take lucatellus balſam one ounce, ſpermaceti ſix drams, ſal prunellæ half an ounce; mix into a ball with honey: if the urine is bloody, add half an ounce of Japan earth.

Should the fever continue, bleed largely, give emollient clyſters, and the cooling, opening drink, till it abates.

If the urine paſſes with difficulty and pain, notwithſtanding theſe means, give this ball, and repeat it twice or thrice a day, till the horſe ſtales freer and without pain, his urine becomes of a right conſiſtence, and is free from any purulent ſettlement.

Take balſam of copivi, or Straſbourg turpentine, and Venice ſoap, of each one ounce; nitre ſix drams, myrrh powdered two drams; make into a ball with honey, and waſh it down with the marſhmallow decoction.

But if this method ſhauld not be ſucceſsful, and the urine continues turbid, grows coffee coloured or fœtid, the horſe loſing his appetite and fleſh, it is a ſure ſign of ulceration in the kidney; which if the above remedies do not ſoon remove, you may depend on it the horſe will go into a conſumption, and is incurable.

As a ſuppreſſion of urine ariſes ſometimes from an inflammation of the kidney; ſo at others, from a paralytic diſorder, diſabling them in their office of ſeparating the urine from the blood: in this latter caſe the bladder is uſually empty, ſo that a horſe will make no motions to ſtale, and if he continues a few days in this condition, his body will ſwell to a great degree, breaking out in blotches all over, and death will ſoon cloſe the ſcene.

If it ariſes from inflammation, bleed largely, and treat the horſe as above recommended; but if not, give ſtimulating clyſters, and ſtrong diuretics, ſuch as the following balls once in four hours; for if a horſe ſtales not in thirty hours, his danger muſt be great.

Take juniper-berries powdered one ounce, ſal prunellæ ſix drams, ætherial oil of turpentine half an ounce, camphor one dram, oil of juniper two drams; make into a ball with honey, and give after it, three or four horns of the marſhmallow decoction and honey.

Or,

Take ſquills powdered two or three drams, nitre half an ounce, or ſix drams; make into a ball with honey.

Or,

The following, which is more forcing, and ſhould be given with caution.

Take cantharides well dried, from one ſcruple to half a dram; camphor diſſolved in oil of almonds, from one dram to two; nitre and Venice ſoap, of each an ounce; mix into a ball with ſyrup of marſhmallows.

When this laſt ball is given, the horſe ſhould be made to drink plenty of water, with gum-arabic diſſolved in it; the following clyſter may alſo be given at the ſame time.

Take of Barbadoes aloes two ounces, the ſame quantity of Venice turpentine, beat up with the yolks

of two eggs; jallap powdered two drams; juniper and bay-berries, each a handful, bruiſed and boiled in two quarts of a decoction of mallows; ſtrain off and mix by degrees with the above, to which add a pint of linſeed-oil.

If the complaint is not removed by theſe means, rub the horſe's reins well with two parts of oil of turpentine, and one of oil of amber; and apply a poultice of garlic, horſe-radiſh, muſtard-ſeed, camphor, and green ſoap, ſpread on thick cloth, over them. Give the horſe alſo two drams of calomel over night, and a moderate purge the next morning. Theſe, perhaps, are the chief and beſt remedies that can be given in this generally fatal diſorder.

When the ſtrangury in a horſe does not ariſe from wind, or dung preſſing on the neck of the bladder, the cauſe is from inflammation, or too long a retention of the urine. Such horſes make frequent motions to ſtale, ſtand wide and ſtraddling, are full, and have their flanks diſtended. In this caſe bleed largely; give the following drink, and repeat it every two hours, for two or three times, till the horſe is relieved.

Take Venice turpentine broke with the yolk of an egg one ounce, nitre or ſal prunellæ ſix drams, half a pint of ſweet oil, and a pint of white wine.

If this drink ſhould not have the deſired effect, the diuretic ball above-mentioned may be given in the ſame manner, omitting the myrrh.

Give the horſe plenty of the marſhmallow decoction, in a quart of which diſſolve an ounce of nitre and gum-arabic, and two of honey.

Horſes ſubject to a diabetes, or profuſe ſtaling, if old, or of weak conſtitution, are ſeldom cured; they ſoon loſe their fleſh and appetite, grow feeble, their coat ſtaring, and they die rotten. Of a young horſe there are more hopes; but he muſt not be indulged with too much water, or moiſt food. Give him the following:

Take jeſuits-bark four ounces, biſtort and tormentil-root, of each two ounces; boil in two gallons of lime-water to the conſumption of half, and give a pint three times a day.

Let the horſe drink two or three quarts a day of lime-water; and if theſe medicines ſhould not ſucceed, give a quart of ſtrong allum poſſet, three or four times a day.

This method is proper alſo for a horſe who ſtales blood; or the following balls may be given for that purpoſe, if the bleeding is profuſe.

Take bole-armoniac one ounce, Japan earth half an ounce, roch allum two drams, elixir of vitriol one dram; make into a ball with conſerve of roſes, and give it every ſix hours.

As this diſorder generally proceeds from too violent exerciſe, over-ſtraining, &c. repeated bleedings in ſmall quantities are abſolutely neceſſary, till the mouths of the veſſels cloſe up. *Bartlet's Farriery, page* 159.

KILN, a kind of ſtove for admitting heat, in order to dry any ſubſtance, as malt, hops, &c. *See the articles* MALT *and* HOPS.

KILN alſo ſignifies a fabric conſtructed for burning lime-ſtone, chalk, &c. into lime.

The kiln commonly uſed for this purpoſe is a large pit, generally round, and of a ſize proportioned to the quantities intended to be burnt. It is wideſt at the top, and narrower, by degrees, as it comes nearer the bottom. The inſide of this pit is ſometimes lined with a wall built of lime-ſtone; but more commonly, and more properly with brick: at the outſide, near the bottom, is a hole, or door, by which the aſhes are taken out; and above that, ſome have an iron-grate, which comes cloſe to the wall round about: but others make an arch with ſtone, or large pieces of chalk; and upon this they lay a layer of ſtone, or of whatever elſe they burn in the kiln; upon this they place a layer of fuel, and ſo on, layer over layer, till the kiln is full; only obſerving that the outermoſt layer be always of the fuel, and not of chalk or ſtone. When the kiln is thus filled, fire is given at the hole underneath; and the lime is finiſhed in a different time, according to the nature of the ſubſtance. That made of chalk is generally burnt in twenty-four hours; but ſtone often requires ſixty hours. Ten buſhels of ſea-coal, or one hundred of faggots three feet long, will burn forty buſhels of chalk, which will yield thirty buſhels of unſlaked lime. Where chalk is ſcarce, the chalk rubbiſh is often worked up into a kind of paſte, with water, and made into a ſort of bricks, which are dried in the air, and then burnt into lime in the common way: but this is not quite ſo good as that which is burnt from the chalk-ſtone.

The experience of late years has ſhewn that it is more profitable to burn lime in kilns ſhaped like a hogſhead; that is, ſmall in circumference at the bottom, gradually wider towards the middle, and then contracting again upwards to the top. This kiln, as Mr. Lummis obſerves in his letter to the Edinburgh Society, publiſhed by Mr. Maxwell, ſhould be made entirely within the ſurface of the ground, on the declivity of a little hill, where that ſituation can be had, ſo as to allow free acceſs to the air-hole or furnace. At the bottom, about a foot from the ground, are iron-bars, placed horizontally aroſs, to give the kiln a good draught, and upon theſe bars are laid, firſt ſmall wood or furze, then ſmall coals, then ſtones about the bigneſs of an egg, then another layer of fuel, and ſo on, increaſing the ſize of the ſtones towards the middle of the kiln, where they may be as big as half a peck, and decreaſing their ſize gradually up to the top, obſerving to lay the ſmalleſt neareſt to the ſides. The ſtones need not be broken ſo ſmall for this kiln, as for thoſe above ground; they will be burnt more truly without raw ſtones, or running into cinders; and not above half the quantity of fuel conſumed in the common way, will be uſed in this.

The following method of conſtructing another kiln, is thus particularly deſcribed in Mr. Maxwell's Collection.

At bottom, the kiln muſt be three feet four inches wide; and at the height of two feet four inches, three feet ſix inches. At the depth of four feet and a half, it muſt be four feet and a half wide. A ſecond ſlope is then made five feet and a half higher, at the end of which, the kiln, then ten feet deep, ſhould be exactly ten feet wide within the walls. A third ſlope ſhould heighten it to 14 feet, where it ſhould be exactly 12 feet and a half wide, likewiſe, within the walls. From thence it is run up to the height of nineteen feet, when it ſhould be rather leſs than fifteen feet wide. The ſlopes muſt be made as gradual as poſſible,

and

and the inner ſurface of the kiln muſt be quite ſmooth, that its contents may fall down equally when the burnt ſtones are drawn out below. By extending a line from a pole fixed in the center of the bottom or floor of the kiln to the ſides, workmen will eaſily be guided in making the above-mentioned ſlopes. This kiln has four vents, oppoſite to one another, and no croſs-irons whereupon to lay the coals and ſtones, they being ſupported by old timber, furze, broom, &c. above which the coals are laid: but if the kiln be built on the ſide of a hill, it can have but three vents. The firſt layer of ſtones above the vents ſhould be cloſely jambed in, and reſt againſt the ſides of the wall. A kiln of the above dimenſions will burn eighty buſhels of lime-ſtones in a day: but it may be made larger, without altering theſe dimenſions, by only adding two or three feet to the height, which will require ſtrong walls. This addition to the height need not be ſloped, but may be made perpendicular.

The late earl of Stair had a kiln at New Liſton, and others in Galloway, built in the ſhape of an egg, opened a little at both ends, and ſet upon the ſmalleſt. This kiln anſwered exceedingly well, and beſides lime-ſtone, burnt any kind of earth that was thrown into it.

Kilns thus built, ſwelling at or about the middle, and contracting again at the top, reverberate more ſtrongly, and make a more intenſe heat, than thoſe which grow wider and wider, and are not contracted.

When the kiln is filled, or finiſhed as it is commonly termed, it ſhould be covered over with ſods or ſtrong turf, to keep the heat as intenſe as poſſible, and hinder the wind from blowing the fire at the top, or rain from abating or extinguiſhing it. The ſtones muſt be broke in pieces before they are thrown into the kiln; otherwiſe the air contained in their cavities, being expanded by the heat, will often make them fly with ſuch violence as to damage the kiln. For this reaſon they ſhould be broken ſmaller for kilns that are above ground, than for thoſe which are underneath. The ſaving of this labour, and of near half the quantity of fuel, renders theſe laſt greatly preferable.

Lime is made of chalk, or of any ſtone that is not too cold, or ſandy, as free-ſtone and the like. All the ſoft ſtones that are of a tolerably cloſe texture, will burn to good lime, as will alſo marble, ſlate, ſea-ſhells, corals, and flints; but this laſt kind of ſtone is more difficult to be burnt into lime than the others, except in a reverberatory kiln, becauſe it is apt to run to glaſs. The hardeſt, firmeſt, and whiteſt ſtones make the beſt lime; and when it is made of chalk, that which is formed of the hardeſt, ſtony kind, is much better than that which is made from the ſoft; but the harder the ſtones are, the more fire it requires to burn them. Both ſorts may be burnt with wood, coals, turf, furze, or fern, which make a very fierce fire.

Theſe kilns ſeem to be intended for burning only one kiln full at a time: but where large quantities of lime are wanted, perpetual kilns, that is, kilns where the fire is kept conſtantly burning, are conſtructed on nearly the ſame principles. Here the iron bars at the bottom are abſolutely neceſſary, in order to take out the lime as ſoon as it is burnt. When ſtone-lime, which requires the moſt violent fire, is burnt in theſe kilns, vents are made near the bottom to be opened occaſionally, according as the wind ſits, that a ſtronger current of air may quicken the fire, and thereby give it the more power. *See the article* LIME.

KILN-ASHES, the aſhes made in kilns where wood, ſtraw, furz, &c. are burnt. Theſe aſhes are a good manure for almoſt any kind of ſoil. In the weſt of England, the farmers ſift them over their corn and graſs; but this muſt not be done in windy weather, becauſe they are ſo very light, that they would eaſily be blown away. They ſucceed beſt when laid on juſt before rain or ſnow.

KINNEL, a powdering-tub.

KIT, a milking-pail, in the form of a churn, with two ears and a cover.

KNAPWEED, the ſame with blue-bottle. *See* BLUE-BOTTLE.

KNOT-GRASS, the ſame with couch-graſs. *See* COUCH-GRASS.

KNOLL, a little round hill.

KNOLLS, a term uſed in ſome counties of England to ſignify turnips.

L.

LAR

LACTARY, a milk-houſe.

LADIES-SMOCK, *Cuckow-flower*, or *Canterbury-bells*, a perennial weed, and common in paſture grounds. The ſtalk is upright, round, and ſmooth. The leaves are winged, with the lobes of the lower ones roundiſh, and of thoſe on the ſtalk oblong. The flowers are large, handſome, and white, or purpliſh, conſiſting of four obtuſe veined petals. The ſeeds are contained in erect compreſſed pods, about an inch in length, divided into two cells, which, when ripe, burſt with a touch, and throw out their ſeeds to a conſiderable diſtance.

LAIRE. *See* LAYER.

LAMB, the young of the ſheep-kind. *See the article* SHEEP.

LAMENESS, in horſes. *See the article* STRAINS.

LAMPAS, an excreſcence in the roof of a horſe's mouth, which is ſometimes ſo luxuriant, that it grows about the teeth, and hinders his feeding.

The cure conſiſts in lightly cauterizing the fleſh with a hot iron, taking care that it does not penetrate too deep, ſo as to ſcale off the thin bone that lies under the upper bars; the part may then be anointed with burnt allum and honey, which is proper for moſt ſores in the mouth. *Bartlet's Farriery, page* 282.

LAND. *See the article* GROUND *and* SOIL.

LARCH-TREE, a genus of trees, whoſe leaves, which are long and narrow, are produced out of little tubercles, in form of a painter's pencil: the cones are produced at remote diſtances from the male flowers on the ſame tree: the male flowers are very like ſmall cones at their firſt appearance, but afterwards ſtretched out in length.

Theſe trees are propagated by ſeeds, which ſhould be ſown in the beginning of March, upon a bed of light ſoil, expoſed only to the morning ſun: or otherwiſe they may be ſown in pots or boxes of light earth, and placed near a hedge, where they may have the morning ſun only. The ſeed ſhould be covered about half an inch thick with fine light earth, and in very dry weather ſhould be gently refreſhed with water. In about ſix weeks, if your ſeeds were good, your plants will come up, at which time you ſhould carefully guard them againſt the rapacious birds, which would otherwiſe pull off the heads of the plants, as they thruſt themſelves out of the ground with their covers on them: and obſerve to refreſh them with water in dry weather, eſpecially if they are ſown in pots or boxes; alſo to keep them clear from weeds, which, if ſuffered to grow among the young plants, will ſoon deſtroy them: nor ſhould they be too much expoſed to the ſun, or ſtrong winds, both which are very injurious to theſe plants while they are young: but in October you

LEA

ſhould, if they are in boxes or pots, remove them into a ſituation where they may be defended from ſharp winds, which are ſometimes hurtful to them, while young; but afterwards, they will indure the ſevereſt weather of our climate.

Theſe trees are very proper for the ſides of barren hills, where few other ſorts will thrive ſo well; nor is this tree very delicate in its ſoil, but will grow much better on poor, ſtrong, ſtony land, than in rich ground; and, during the ſummer, they appear very beautiful; but in autumn they caſt their leaves, whereby ſome people have been deceived, by ſuppoſing them dead, and have deſtroyed them.

From the wounded bark of this tree exudes the pureſt Venice turpentine; and on the body and branches of it grows the agaric, which is a drug uſed in medicine.

LATH, a long, thin, and narrow ſlip of wood, nailed to the rafters of a roof or cieling, in order to ſuſtain the covering.

Theſe are diſtinguiſhed into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, ſap laths, and deal laths; of which the two laſt are uſed for cielings and partitions, and the firſt for tiling only.

Laths are alſo diſtinguiſhed according to their length, into five feet, four feet, and three feet laths; though the ſtatute allows but of two lengths, thoſe of five, and thoſe of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickneſs; but they are commonly leſs.

LATH-BRICKS, bricks much longer than ordinary, uſed inſtead of laths, for drying malt; for which purpoſe they are extremely proper, as not being liable to catch fire, and retaining the heat much longer than thoſe of wood; ſo that a very ſmall fire will ſerve after they are once heated.

LATHE, a word uſed in ſome counties in England, to ſignify a barn.

LEAF, a part of a plant, commonly very thin and flat, growing in the ſpring, and falling off in the autumn.

Leaves are the ornament of the twigs, and conſiſt of a very glutinous matter, being furniſhed every where with veins and nerves. Their office is to ſubtilize the nouriſhing ſap, and convey it to the little buds; and likewiſe they ſerve to cover the flowers and fruits with their ſhade, and keep them from other inconveniences; they are to trees what hair is to the human body.

Dr. Grew obſerves, that the fibres of leaves conſiſt of two general kinds of veſſels, namely, for ſap, and for air; and are ramified out of greater into leſs, as veins and arteries are in animals.

Mr.

Mr. Frederick of Augſbourg, a celebrated gardener, took from the tree a leaf of the opuntia or Indian fig-tree; and ſetting it in the earth, it immediately took root, and produced bloſſoms and fruit.

The diſtinction of leaves, made by thoſe who have written on botany, are the following.

A ſimple leaf is that which is not divided to the middle.

A compound leaf is divided into ſeveral parts, each reſembling a ſimple leaf, as in liquorice, &c.

A digitated leaf is a compound leaf divided into ſeveral parts, all of which meet together at the tail, as in the hemp, black hellebore, &c.

A trifoliated leaf is a digitated leaf, conſiſting of three fingers, as the trefoil, &c.

A quinquefoliated leaf is a digitated leaf, conſiſting of five fingers, as in the quinquefolium.

A pennated leaf is a compound leaf divided into ſeveral parts, each of which is called a lobe, placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is ſaid to be unequally pennated, as in the goats rue, &c. and equally pennated, when it is not terminated by an odd lobe, as in the caſſia; when the lobes are all nearly of the ſame form and bigneſs, it is called an uniform pennated leaf, as in the liquorice; when they are not ſo, it is ſaid to be difform, as in the agrimonia.

A winged leaf is, as it were, divided into ſeveral pennated leaves, as in the orobus, &c.

A ramoſe leaf is that which is ſtill farther divided than the winged leaf, as in the oſmund royal, female fern, &c.

An entire leaf or lobe is that which has no diviſion on its edges, as in the apple-tree, &c.

A ſinuated leaf is that which is cut about the edges into ſeveral long ſegments, as in common mallows.

A ſerrated leaf is that which is cut about the edges into ſeveral acute ſegments, reſembling the teeth of a ſaw, as in the nettle, &c.

A crenated leaf is that which is cut about the edges into ſeveral obtuſe ſegments, as in the betony, &c.

A lacinated or jagged leaf is that which is cut about the edges into ſeveral pretty deep portions, in an irregular manner, as in the horned poppy, &c.

If the ſurface of the leaves are altered, by reverſing the branches of trees on which they grow, the plants are ſtopped in their growth, until the footſtalks are turned, and the leaves recover their former poſition. This ſhews how neceſſary it is to ſupport all thoſe weak ſhoots of plants, which are naturally diſpoſed for upright growth, which either twine about the neighbouring trees for ſupport, or that put out claſpers, by which they take hold of whatever trees or plants grow near them, and are thereby ſupported; and, on the contrary, how abſurd is that practice of tying up the ſhoots of thoſe plants which are naturally diſpoſed to trail upon the ground, for in both theſe caſes nature is reverſed, and conſequently the growth of both ſorts of plants is greatly retarded.

This is one of the great functions for which the leaves of trees and plants are deſigned; but, beſides this, there are others of equal importance to the well-being of plants and fruits; the firſt is, that of the footſtalks and leaves nouriſhing and preparing the buds of the future ſhoots, which are always formed at the baſe of thoſe footſtalks, and during the continuance of the leaves in perfect health, theſe buds increaſe in their magnitude; and, in the deciduous trees, are brought to maturity before the footſtalks ſeparate from the buds in autumn; but if by accident the leaves are blighted, or if the entire ſurface of the leaves are cut off, and the footſtalks are left remaining, the buds will decay for want of that proper nouriſhment which is conveyed to them from the leaves; ſo that whenever trees are diveſted of their leaves, or thoſe leaves are cut, or otherwiſe impaired, though it may in either caſe happen when the buds may be nearly formed, yet if it is before the footſtalks ſeparate naturally from their branches, the future ſhoots will be weakened in proportion to the time when this is done; therefore from all the experiments which have been made in order to know how ſerviceable the leaves of trees and plants are to their well-being, it has been found, that when the plants have been diveſted of their leaves, or their leaves have been eaten or cut, during their growth, the plants have been remarkably weakened thereby. This ſhould teach us not to pull or cut off the leaves of trees, or plants, on any account, while they retain their verdure, and are in health; and this ſhews how abſurd that common practice is, of feeding down wheat in the winter and ſpring with ſheep; for by ſo doing, the ſtalks are rendered very weak, and the ears are in proportion ſhorter; nor are the grains of corn ſo plump and well nouriſhed, as that which is not fed down upon the ſame ground: this is a fact which we can aſſert from many years experience. It is very evident, that graſs which is often mowed, the blades will be rendered finer in proportion to the frequency of mowing it, yet the ſpecies of graſs is the ſame with that on the richeſt paſtures; ſo that although this may be a deſirable thing for lawns, &c. in gardens, yet where regard is had to the produce, this ſhould be avoided.

Another principal uſe of the leaves, is to throw off by tranſpiration what is unneceſſary to the growth of the plants, anſwering to the diſcharge made by ſweat in animal bodies; for as plants receive and tranſpire much more, in equal time, than large animals, ſo it appears how neceſſary the leaves are to preſerve the plants in perfect health; for it has been found by the moſt exact calculation, made from repeated experiments, that a plant of the ſun-flower receives and perſpires, in twenty-four hours, ſeventeen times more than a man.

We ſhall beg leave to mention a few, out of the many experiments which have been made by M. Bonnet, of Geneva, to prove that moſt leaves imbibed the moiſture of the air on their under ſurface, and not from their upper; they are as follows:

He gathered the leaves of ſixteen ſorts of herbaceous plants when fully grown; of each he put ſeveral leaves upon the ſurface of water in glaſs vaſes, ſome were poſited with their upper ſurface, and others with their under ſurface upon the water; theſe were adjuſted exactly to the ſurface of the water, with great care not to let any moiſture reach their oppoſite ſurfaces, and the ſame care was taken to prevent their footſtalks from receiving any moiſture. The glaſſes in which theſe leaves were thus placed, were kept in a cloſet, where the air was very temperate; and as the water in the glaſſes evaporated, there was, from time to time, a ſupply of freſh, which was added with a ſyringe, ſo that the leaves were not diſturbed. The leaves were taken from the following plants; the plantain, the mullein, the wake Robin, the great mal-

low, the nettle, the marvel of Peru, the kidney-bean, the ſun-flower, the cabbage, the baum, the cock's-comb, the purple leaved amaranth, ſpinach, and the ſmaller mallow.

Six of theſe ſorts he found continued green a long time, and theſe were with different ſurfaces upon the water: they were of the following ſorts, the wake Robin, the kidney-bean, the ſun-flower, the cabbage, ſpinach, and the ſmall mallow; among the others, the following ſorts were found to draw the moiſture better with their upper than with their under ſurface, the plantain, the mullein, the great mallow, the nettle, the cock's-comb, and the purple amaranth.

The leaves of the nettle, whoſe under ſurfaces were placed upon the water, were decayed in three weeks; whereas thoſe whoſe upper ſurfaces touched the water, laſted three weeks.

The leaves of the mullein, whoſe under ſurfaces were next the water, did not continue freſh more than five or ſix days, whereas thoſe whoſe upper ſurfaces were next the water, laſted five weeks.

The leaves of the purple amaranth, whoſe upper ſurfaces were next the water, continued freſh three months; whereas thoſe whoſe under ſurfaces touched the fluid, were decayed in a week.

The leaves of the marvel of Peru and the baum, appeared to have the advantage, whoſe under ſurfaces were next the water.

The leaves of the wake Robin, and of the cock's comb, whoſe footſtalks only were put into the water, continued freſh a longer time than thoſe which were placed with either ſurface upon the water.

The leaves of the great mallow, the nettle, the ſun-flower, the marvel of Peru, and the ſpinach, whoſe footſtalks were plunged into the water, continued freſh a ſhorter time, than theſe which had either of their ſurfaces upon the water.

The leaves of the mullein, plantain, and amaranth, which received the water at their footſtalks, continued freſh much longer than thoſe whoſe under ſurfaces touched the water.

It is not difficult to explain the reaſon of this fact; for the orifices of the ſap-veſſels in the footſtalks are much larger than thoſe of either ſurface, ſo that the water inſinuates itſelf in greater quantities, and with more eaſe, in the firſt than by the ſecond way.

After this the ſame gentleman made experiments on the leaves of ſixteen ſorts of trees and ſhrubs, of the following ſorts: the lilac, the pear-tree, the vine, the aſpin, the laurel, the cherry-tree, the plum-tree, the horſe-cheſnut, the white mulberry, the lime-tree, the poplar, the apricot, the walnut, the filbert, the oak, and the creeper.

Among theſe ſpecies he found, that the lilac, and the aſpin, imbibed the water equally with either their upper or under ſurface; but in all the other ſorts, the under ſurfaces imbibed it in much greater quantities than the upper. The difference was very remarkable in the leaves of the white mulberry, for thoſe whoſe upper ſurfaces were laid upon the water, faded in five days; whereas the others, whoſe under ſurfaces were next the water, preſerved their verdure near ſix months.

The vine, the poplar, and the walnut, afforded very remarkable inſtances, how little diſpoſed the upper ſurfaces of the leaves of ligneous plants are to imbibe the moiſture: for the leaves of theſe three ſorts, whoſe upper ſurfaces were applied to the water, decayed almoſt as ſoon as thoſe which had no nouriſhment.

In all the experiments made by this curious gentleman upon the various leaves of trees and herbs, it is remarkable that all thoſe leaves, which imbibed their moiſture by their upper ſurface, were ſuch as had that ſurface covered over with hairs or down; and, on the contrary, where the under ſurface was garniſhed with either hairs or down, the nouriſhment was imbibed by that ſurface. He alſo mentions many experiments made by himſelf, and alſo by M. Duhamel de Monceau, of the Royal Academy of Sciences at Paris, in rubbing the leaves over with varniſh, oil, wax, and honey, to ſee the effect of theſe upon various leaves, ſome of which were rubbed over on both ſurfaces, others only upon one; ſome only a part of the ſurfaces, others the edges of the leaves were rubbed over, and in ſome only the footſtalks of the leaves. They likewiſe anointed the trunks of ſome trees and ſhrubs, leaving the leaves and branches in their natural ſtate.

The reſult of theſe experiments was, that where the leaves were covered with varniſh on both ſides, they preſently decayed; and where they were anointed with other things, the leaves continued a ſhorter time than others, in proportion as the things were more penetrating; and where one ſurface only was anointed, they continued much longer than thoſe which were anointed on both; and where the pedicle alone was anointed, they continued ſtill longer: but the anointing of the trunks made no ſenſible alteration, except in very hot weather; when they were both of opinion the anointing them were of ſervice, by hindering the too great tranſpiration, which tend to weaken the trees: for they obſerved, that thoſe trees which were varniſhed, ſuffered leſs from the violent heats, than the trees which were left in their natural ſtate.

M. Bonnet alſo obſerved, that the tender parts of the leaves which were varniſhed were deſtroyed by it, and the tough fibres only left remaining.

We may therefore reaſonably conclude, that one great uſe of leaves is what has been long ſuſpected by many, viz. to perform, in ſome meaſure, the ſame office for the ſupport of vegetable life, as the lungs of animals do for the ſupport of animal life: plants, very probably, drawing through their leaves ſome part of their nouriſhment from the air. *Miller's Gard. Dict.*

LEAP, or *Lip*, half a buſhel.

LEASE, *Lea*, *Lay*, or *Ley*, implies graſſy ground, meadow ground, or unploughed ground, kept for cattle.

LEASE alſo ſignifies the letting of lands, tenements, &c. unto another for life; a term of years, under a reſerved rent.

LEES, the more groſs and ponderous parts of liquors, which, being ſeparated by fermentation, fall to the bottom.

The lees of wine, beer, ale, and oil, are excellent manures.

LEET, a little court held within a manor, and called the king's court, on account that its authority to puniſh offences originally belonged to the crown, and from thence deſcended to inferior perſons.

LENTIL, or *bitter Vetch*, the name of a plant of the vetch or tare kind, cultivated in ſome parts of England as fodder for cattle.

Lentils grow to a foot or a foot and a half high, with ſtalks and leaves like thoſe of tares, but ſmaller; and like them they bear their ſeeds, generally three or four in little pods. Theſe ſeeds are round, hard, ſmooth, and flat, but thicker at the ſides. There are two ſorts of lentils, the

the white and yellow; but the latter affords the greater quantity of fodder.

The ſeeds of this plant are commonly ſown in March, where the land is dry, but in moiſt ground the time is in April. The uſual quantity of ſeed allowed to an acre of land is from one buſhel and a half to two buſhels. If theſe are ſown in drills in the ſame manner as peaſe, they will ſucceed better, than when they are ſown broad-caſt. The drills ſhould be a foot and a half aſunder, to allow room for the hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the lentils, and ſtarve them. *Miller's Gard. Dict.*

LIME, a ſoft friable ſubſtance, obtained by calcining or burning ſtones, ſhells, and the like.

The moſt certain way to know whether any ſort of ſtone be fit for making lime, is to drop upon it a little aqua-fortis, ſpirit of ſea-ſalt, or oil of vitriol. All ſtones on which the above, or any other ſtrong acid efferveſces or riſes in bubbles, are lime-ſtones, or will burn to lime; and the ſtronger the efferveſcence is, the fitter they are for that purpoſe. All country gentlemen ſhould keep ſome ſuch ſpirit by them, to try the nature of the ſtones that may be found on their eſtates.

All lime is a very good manure, but that made of ſtone is much better than what is made of chalk. It makes the greateſt improvement upon light ſandy ſoils, or upon a dry gravel; wet and cold gravel is leſs benefited by it, and cold clay the leaſt of all. The common allowance is a buſhel to a pole ſquare, or a hundred and ſixty buſhels to an acre. Mr. Lummis laid after the rate of three hundred buſhels on an acre, and found it anſwer extremely well: but that was upon a ſtrong clay. His method of uſing it, as communicated to the Edinburgh Society, and the reſult, he ſays, of what he has experimented to be beſt, is as follows:

In the month of October, he lays together three or four of the largeſt ſtones (burnt into lime) on the ſward or turf of a ſtrong clay ground; or as many of the ſmall ſtones as are equal to the large ones, ſo that ſeventy or eighty bolls (two hundred and eighty, or three hundred and twenty buſhels) may complete an acre. If rain falls, it melts immediately; if not, it will melt and ſlake in forty-eight hours, or leſs, according to the moiſture of the air. He then ſpreads it directly, leaving no part of it upon the ſpot where the ſtones were laid. This done, he lets it lie twelve months, or till the month of November after the October twelve months, when he ploughs it in, and lets it remain in that ſtate all the winter, during which froſts and rains mellow and prepare the ground for the next ſpring ploughing, and render it fit for barley. He prefers this method to laying the lime on in powder, becauſe, in this laſt way, it is apt to be blown about with the wind, to the great detriment of both men and horſes, ſuch as ſpoiling the men's eyes, hair, and cloaths, and the eyes and hair of the horſes, making their coats look dry and ugly, beſides loſing much of the lime.

The lime laid in the month of October, as above directed, on a ſtrong arable land, which has been ſome years under graſs, and continuing ſpread for about twelve months before it be ploughed in, has been found ſo to alter the graſs to a fine natural clover, that, by feeding of ſheep or black cattle upon it, it has paid the whole charge the firſt year by the graſs; and cattle will chooſe rather to feed on this ground than any other, and grow fatter. If the ground be looſe and open, it may be ploughed in the enſuing March, if limed in October. In either way, it ſo far meliorates the ſward, and the ſoil, that the beſt of crops may be expected for three or four years; and by laying ſome dung upon it the 4th or 5th year, two or three crops more may be obtained; after which the ground will be in excellent order to lay down with graſs ſeeds.

Notwithſtanding that lime is ſo very good a manure, Mr. Lummis prefers marle, if it can be had within the ground, or near the place where it is to be uſed; for tho' it be more chargeable at firſt, yet, laſting five times as long, it is in the end much cheaper. He generally lays near two hundred loads of it upon an acre, at about ſeven or eight buſhels to the load.

Mr. Evelyn adviſes mixing the lime with the turf or ſward, laying them alternately, turf on lime, and lime on turf, in heaps for ſix months; by which means it will become ſo rich and mellow, as to diſſolve and run like aſhes, and carry a much more cheriſhing vigour, than if uſed alone in a greater quantity, and without danger of burning out and exhauſting the vegetative virtue which it ſhould preſerve. It is likewiſe greatly bettered by being mixed with dung, or with mud drawn from the bottom of ponds or rivers. In Weſtmorland, they reap fine crops of barley from their ſandy lands, by manuring them with lime and cow-dung mixed together.

The nature of lime on land is like that of chalk: it works downwards, as the farmers expreſs it, and is therefore beſt treated in the ſame manner, laying it upon a lay the year before it is to be ploughed up. When uſed on land which lies upon a deſcent, it ſhould by all means be mixed with dung, and laid principally on the higher part of the land; the conſequence of which will be, that the rain will waſh out the virtues of the lime and dung together, and carry them to the lower parts as it runs down. In fact, it does better on any land, when mixed with dung, than either of them alone. This is particularly obſerved in Shropſhire, where they lay dung and lime together, about twenty load of the former, and only twenty buſhels of the latter, on an acre of ground. In Leiceſterſhire, they ſow or ſcatter the lime on wheat land when they ſow the wheat; but on barley-land, the laſt earth but one, leſt it ſhould burn the barley if ſowed with it in the ſpring. They allow five quarters to an acre of each, reckoning by the meaſure in which it comes from the kiln; for after it is ſlaked, thoſe five quarters will make near ten.

Lime is thought to make corn grow with a thin huſk. It is a great deſtroyer of moſs and ruſhes, even after it has been ſlaked; as quick lime is of the remnants of furzes, after the old buſhes have been grubbed up. Its hot quality renders it apt to over-burn dry ſoils. It certainly is moſt efficacious when ſpread directly from the kiln.

Mr. Liſle, whoſe account of lime is almoſt unintelligibly perplexed and confuſed, thinks it is beſt, eſpecially on lands that work mellow, to ſpread and plough in this manure as ſoon as it is ſlacked, rather than to let it lie long in heaps covered with earth. He very properly gives it as a rule to all huſbandmen, to be cautious of liming ground, and then ploughing out the heart of it; the bad conſequences of which he himſelf experienced. "I limed, ſays he, ſome years ago, in Wiltſhire, ſeven acres for an experiment, and laid down one acre to its own natural graſs. In two years time this graſs was, and

ſtill

ſtill is, worth forty ſhillings an acre. The third year, I laid down another acre, which is ſtill worth thirty ſhillings a year. The reſt, which I ploughed five or ſix years longer, is not worth fifteen groats an acre. I have experienced the like in burn-baking ground."

The practice of Lower Normandy, where lime is chiefly uſed on lands newly broken up, is thus related by M. Du Hamel.

After giving theſe lands a ſhallow ploughing, they carry on the lime as it comes from the kiln, and lay about an hundred weight of it in a heap on every ſquare perch; ſo that the heaps lie at a perch diſtant from one another; they then raiſe the earth all round the heaps, like ſo many baſons: the earth which forms the ſides of theſe baſons ſhould be a foot thick: and, laſtly, they arch the heaps over with earth, ſix inches thick. The lime ſlakes under this covering, and is reduced to powder; but at the ſame time it increaſes in bulk, and thereby cracks the earth. If theſe cracks be not carefully ſtopped, rain will get through them, and reduce the lime into a paſte, or kind of mortar, which will not mix with the earth, or anſwer the end propoſed. Farmers are therefore very careful to examine the heaps from time to time, and ſtop the cracks. Some only preſs down the top of the heap with the back of a ſhovel: but this method is liable to a conſiderable inconvenience; for if the lime be in a paſte within the heap, it is by this means beat together in ſuch manner, that it becomes ſtill more difficult to mix it with the earth: for which reaſon it is better to ſtop the crevices, by throwing a little freſh earth over the heap.

When the lime is thoroughly ſlaked, and reduced to powder, the heaps are cut with a ſhovel, and the lime is mixed as well as poſſible with the earth that covered it. This mixture is then thrown up in heaps again, and left expoſed to the air for ſix weeks or two months; for then the rain will not hurt it.

About the beginning of June, this compoſt of lime and earth is ſpread upon land: but not by throwing it about unequally, or at random: on the contrary, it is taken up by ſhovelfuls, and diſtributed in little heaps, at equal diſtances, on each perch of ground, it having been obſerved, that theſe little heaps promote vegetation, more than if the manure was ſpread uniformly all over the field; nor is it at all heeded, if ſmall intervals remain unlimed between each ſhovelful. The field is afterwards ploughed, for the laſt time, very deep: then, towards the end of June, it is ſown with buck-wheat, which is covered with a harrow; and if any clods remain, they are broken with a hoe.

Buck-wheat occupies the land about a hundred days; ſo that this grain, ſown about the end of June, is gathered about the end of September. When the ſtalks and roots of this plant are dead and dried, the ground is ploughed up, and immediately ſowed with wheat, which is harrowed in. After the wheat has been reaped, the land is ploughed as ſoon as poſſible. It is ploughed for the laſt time, in February or March, in order to ſow oats; or in April for barley: but in this caſe it is turned up two on three times, to make it fine. All theſe different grains are harrowed in. A roller is paſſed over the oats when they are come up; and if any clods remain in the barley, they are broken with a hoe.

In the next February or March the land is ploughed again, in order to ſow it with grey peaſe or vetches: and after theſe pulſe have been reaped, one or two ploughings are given, to prepare it for wheat in the enſuing autumn.

The next year oats are ſowed, ſometimes mixed with a little clover; and then the ground is laid down to paſture for three or four years.

Sometimes no buck-wheat is ſowed on land newly broken up; but it lies fallow, from the month of March, when it was firſt ploughed, till October, when it is ſowed with wheat, after receiving ſeveral ploughings during the intermediate time. Theſe lands being, by this means, brought to a tolerable tilth, not above three quarters of the quantity of lime above-mentioned is uſed on them, and they generally bear a better crop than thoſe which are firſt ſowed with buck-wheat.

Some farmers think a perch too great a diſtance for conveniently ſpreading the lime. They therefore make the heaps leſs, and increaſe their number in proportion. Others lay their lime in ridges, from one end of the field to the other; which facilitates the ſpreading of it. Being perſuaded that lime is moſt efficacious when it lies ſhallow in the ground, they firſt plough it in, and then give a ſecond ploughing before they ſow, which brings it again near the ſurface.

Lime is commonly ſaid to enrich land greatly at firſt, but afterwards, when its efficacy is exhauſted, to leave the ground more barren than it was before. Lime readily unites with every unctuous ſubſtance, and renders it more ſoluble in water. By this means, all ſuch particles mixed with the ſoil may be more ſpeedily converted to the nouriſhment of vegetables, than they might otherwiſe be. Indeed, if the farmer's avarice, or want of judgement, tempt him to over-crop the ground, it may be left without matter fit to nouriſh plants, till a freſh ſupply is brought; but if it be judiciouſly cropped, and left in good heart under graſs, or any other produce which does not impoveriſh the ſoil, the effect of the lime will be more durable, and more advantageous than is generally imagined.

LIME-KILN. *See the article* KILN.

LIME-STONE, a ſpecies of ſtone which will burn into lime. *See the article* LIME.

LIME-TREE, or *Linden-Tree*, a beautiful tree for walks, and other decorations, in parks, &c. and of which Mr. Miller has enumerated four ſpecies.

All the ſpecies of the lime-tree are eaſily propogated by layers, which will, in one year, take good root, and may then be taken off, and planted in a nurſery, at four feet diſtant row from row, and two feet aſunder in the rows. The beſt time to lay them down and to remove them, is, when their leaves begin to fall, that they may take root before the froſt comes on, though they may be tranſplanted any time from September to March, in open weather; but if the ſoil be dry, it is much the better way to remove them in autumn, becauſe it will ſave a great expence in watering, eſpecially if the ſpring ſhould prove dry. In this nurſery they may remain four or five years, during which time the ground ſhould be dug every ſpring, and conſtantly kept clear from weeds, and the large ſide ſhoots pruned off, to cauſe them to advance in height; but the ſmall twigs muſt not be pruned off from the ſtems, becauſe theſe are abſolutely neceſſary to detain the ſap, for the augmentation of their trunks, which are apt to ſhoot up too ſlender, when they are entirely diveſted of all their lateral twigs. If the ſoil in which they are planted, be a fat loam, they will make a prodigious progreſs

progreſs in their growth, ſo that in three years time they will be fit to tranſplant out where they are to remain.

They may alſo be propagated by cuttings; but as this method is not ſo certain as by layers, the other is generally practiſed. In order to obtain proper ſhoots for laying down, a lime-tree is cut down cloſe to the ground, from the roots of which a great number of ſtrong ſhoots are produced the following year; theſe will be large enough to lay down the ſucceeding autumn, eſpecially if the ſmalleſt of them are cut off cloſe early in the ſpring; for when too many ſhoots are ſuffered to grow during the ſummer, they will be much weaker, than if only a ſufficient quantity be left. For the manner of laying down theſe ſhoots, *ſee the article* LAYER.

The timber of the lime-tree is uſed by carvers, it being a ſoft, light wood, as alſo by architects for framing the models of their buildings; the turners likewiſe uſe it for making light bowls, diſhes, &c. but it is too ſoft for any ſtrong purpoſes. *Miller's Gard. Dict.*

LINDEN-TREE. *See the preceding article.*

LING, heath.

LINSEED, the ſeed of the flax. *See the article* FLAX.

LIQUORICE, a plant propagated for medicinal uſes. It grows to about four or five feet high; its ſtalks are hard and woody; its leaves ſmall and roundiſh, ſtanding together on the two ſides of a rib, and making what botaniſts call a winged leaf.

A correſpondent of the editors of the Muſeum Ruſticum has given the following directions for cultivating this plant, founded on a long ſeries of experience.

"The common culture of liquorice is not difficult to be learned; and this with proper attention, will enable any thinking farmer, that knows his buſineſs, to cultivate it to advantage.

"This plant thrives beſt on a deep, looſe, rich mould; and if it is freſh land, that has not for many years borne corn, the profit will be the greater, as the crop will be larger, and the roots of a finer quality.

"A rich ſandy ſoil, provided it is deep, will do well for this plant; and it muſt always be remembered, that too much moiſture is its greateſt enemy: let no one therefore attempt to plant it on a damp clay, leſt the whole crop be cankered.

"Land cannot be made too fine, nor dug too deep, for liquorice: it ſhould be, at leaſt, moved with the ſpade to the depth of two feet and a half, and if a little deeper, ſo much the better.

"If the land, on which the liquorice-ſets are to be planted, is freſh, rich, and in good heart, it needs no manure for the firſt crop; but if it has been for ſome years in tillage, the planter will do well to give it, in the ſummer time, a good dreſſing of very rotten dung, lime, and coal-aſhes, or ſoot, mixed together, ſome months before, in a compoſt: the quantity muſt be regulated by the ſtate of the land, always remembering that this plant requires a great deal of nouriſhment, and is a great impoveriſher of land, though it extracts much of its nouriſhment, or food, from a conſiderable depth, at a diſtance from the ſurface; ſome of the roots running five or ſix feet, at leaſt, into the ground.

"When the ground is properly prepared, reduced to a very fine tilth, and laid level, ſome liquorice runners, or ſets, are to be procured. Theſe muſt be cut into pieces, about eight or nine inches long each, and planted in rows, with dibbers armed with iron points. I make my rows two feet aſunder, put my ſets fifteen inches from each other, and when three rows are planted on a ſix-feet bed, I allow two feet more of interval betwixt bed and bed.

"When I put in my ſets with the dibber, I leave the upper end of each ſet juſt level with the ſurface of the ground: I ſhould have obſerved, that I have all my ſets carefully inſpected before they are carried into the field, to ſee that each of them has one, if not two eyes, or buds, without which they would make no ſhoots.

"When the whole ſpot of ground is planted, I make my labourers dig up the intervals one ſpit deep, and ſpread the earth on the beds: this raiſes them about two inches above the head of the ſets, and by lowering the intervals, ſerves in wet ſeaſons to drain the beds. I generally contrive to get this work done by the laſt week in September; but in favourable years, the middle of October is not too late.

"If the weather proves mild, I have no farther trouble with them during the winter; but if it is likely to freeze hard, I cover the beds with peaſe-haulm, or long dung, or ſome ſuch matter, to forward the growth of the roots in the ſpring, and protect them during the winter, from the froſts.

"Early in the ſpring, on the firſt appearance of the weeds, I allow my liquorice a thorough hoeing; and this is ſeveral times repeated in the dry weather of the ſummer.

"The winter following, I again cover them with long dung, and in the ſpring, before the roots begin to ſhoot, I have the ſpaces betwixt the rows on the beds looſened with a ſpade, and the intervals are well dug: immediately after which, I give the land a ſlight dreſſing of coal-ſoot, ſown by hand: it ſhould be thick enough to make the land look black: this the firſt rains waſh in, and it greatly warms and invigorates the plants.

"The ſecond and third ſummers, all I have to do, is to keep my crop clear of weeds: this indeed, is very neceſſary, and the hoeings for this purpoſe muſt be more or leſs frequent, according to the ſeaſon; generally, three times in the ſummer are quite ſufficient, eſpecially if the land was well prepared before the ſets were planted.

Many good ſenſible farmers, whom I have known to cultivate this plant, in autumn have a practice of cutting down the ſtalks, whilſt they are in full ſap, thinking thereby to ſtrengthen the roots. I differ from them, however, in opinion, and am rather apt to imagine, that this cutting of the ſtalks, whilſt the ſap is in motion, muſt be prejudicial to the roots. It is, therefore, my cuſtom, always to defer cutting off the ſtalks, till they are withered, and begin to decay; nature then indicating, that an abſtraction will be of ſervice.

"Theſe roots ſhould have three ſummers growth before they are fit to take up: it is very ſeldom that they have attained a proper ſize at two years end; and if you leave them longer than three years in the ground, the roots are apt to grow ſticky, and loſe a part of their ſaccharine quality.

"I never take them up till the ſap is entirely at reſt, and the leaves and ſtalks are withered: they are then in prime order, and fitteſt for ſale.

"If theſe roots are taken up while the ſap is in motion, either early in the autumn, or late in the ſpring, they are apt to ſhrivel, and loſe much of their weight, and are, beſides, more diſpoſed to ferment and periſh.

"The beſt way of taking them up is, to dig the ground over as deep as the principal roots run, having pickers ready

ready to gather up the roots as fast as they are thrown up by the spade.

"My general practice is to get rid of my roots as soon as I conveniently can: and I find it better so to do, than to wait for the rising of the markets. I have had, from one acre of fine, fresh, rich land, above 3000 pounds of saleable root, which has produced me above sixty pounds; but this many years ago, my crops not being general now so large.

"When I have taken up a crop of this root, if it was planted on fresh land, I generally prepare the same ground to yield me another crop; and this takes me near a year.

"I, in the first place, give it, during the winter frosts, a thorough good dressing of well-rotted dung, mixed with lime: of this I lay on large quantities, still having regard to the condition of the soil, and ploughing it well in the ensuing summer.

"In such loose soils, as are proper for this plant, there is no occasion to dig the land for this crop, the taking up the roots having stirred it to a great depth: this, with three or four summers ploughings, is sufficient.

"As to the rest, I manage the same as I did for the preceding crop.

"If the land, which has borne me a crop of liquorice-root, was not fresh land when it was planted, but had been any time in tillage, I scarcely ever chuse to plant it again with the same crop, without allowing several years of interval, at least seven; but in this case, I frequently sow oats in the spring, to abate the rankness of the soil; and it will then, with a very slight dressing, give me a good crop of wheat.

"In my method of cultivating this plant, I always allow space enough for the roots to extend in search of food; and this is my reason for planting my rows at two feet distance: I am, besides, very careful of keeping them clear of weeds, and that, particularly, during the first summer; being very sensible that, without this precaution, they would be in great danger of being choaked up, and robbed of their proper share of nourishment; particularly, they would receive no benefit from the dews, which are so friendly to vegetation; and even the sun's warmth would be, in a great measure, kept from the roots by the shade of the weeds.

"Many, who plant liquorice, allow much less space than I do betwixt the rows, and will yet, the first summer, take off a crop of onions, or spinage, or young carrots, and think it so much clear profit; but the question is, whether these crops may not, during the time they are on the ground, be, to all intents and purposes, deemed weeds, having nearly, if not altogether, as bad effects, as weeds would if permitted to grow with the crop.

"Some, worse farmers, continue this practice two years of its growth; but it is quite needless to condemn this method of culture, as it cannot but stand self-condemned.

"In the dressings I give my land, for preparing it to receive this plant, experience has convinced me that lime is a much sweeter manure than stable-dung: in fact, this last is not, on any account, to be used till it is quite rotten, and then lime is very properly added to it as a corrector.

"Some friends of mine, who live very near London, have attempted to cultivate this plant on their lands; but they find it does not answer; and this, on account of the great richness of the soil, owing to the great quantity of London dung laid on it. It is true, the roots were at three years end larger than mine; but they were not so bright, but had a blacker coat, and were deemed greatly inferior in quality.

"Should any of your readers be inclined to cultivate this plant, by following these directions, not implicitly, but according to their discretion, the circumstances of their soil, &c. considered, they cannot well fail succeeding." *Museum Rusticum, vol.* I. *p.* 252.

LITTER, the straw laid under horses, &c.

LIZENED *Corn*, lessened, shrunk, or lank corn.

LOAM, an earth composed of dissimilar particles, hard, stiff, dense, and rough to the touch, and composed of sand and a tough viscid clay.

LOE, a little round hill, or heap of stones.

LOG, a large, shapeless piece of wood.

LOOP, a hinge of a door.

LOP, a flea.

LOPPED *Milk*, such as stands till it sours and curdles of itself.

LOPPING, the cutting off the side branches of trees.

It is very observable that most old trees are hollow within; which does not proceed from the nature of the trees, but is the fault of those who have the management of them, who suffer the tops to grow large before they lop them; as the ash, elm, hornbeam, &c. and persuade themselves, that they may have the more great wood; but in the mean time, do not consider that the cutting off great tops endangers the life of a tree; or, at best wound it so, that many trees yearly decay more in their bodies than the yearly tops come to; and at the same time that they furnish themselves with more great wood, they do it at the loss of the owner. And, indeed, though the hornbeam and elm will bear great tops, when the body is little more than a shell; yet the ash, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays. Therefore, if once these trees decay much in the middle, they will be worth little but the fire; so that if you find a timber-tree decay, it should be cut down in time, that the timber be not lost.

The lopping of young trees, that is, at ten or twelve years old at most, will preserve them much longer, and will occasion the shoots to grow more into wood in one year, than they do in old tops at two or three. Great boughs, ill taken off, spoil many a tree; for which reason they should always be taken off close and smooth, and not parallel to the horizon; and cover the wound with loam and horse-dung mixed, to prevent the wet from entering into the body of the tree.

When trees are at their full growth, there are several signs of their decay; as the withering or dying of many of their top branches; or if the wet enters at any knot; or they are any wise hollow or discoloured; if they make but poor shoots; or if woodpeckers make any hole in them.

This lopping of trees is only to be understood for pollard-trees; because nothing is more injurious to the growth of timber-trees, than that of lopping or cutting off great branches from them. Whoever will be at the trouble of trying the experiment upon two trees of equal age and size, growing near each other, to lop or cut off the side branches from one of them, and suffer all the branches to grow upon the other, will in a few years,

years, find the latter to exceed the other in growth every way; and this will not decay near ſo ſoon.

All ſorts of reſinous trees, or ſuch as abound with a milky juice, ſhould be lopped very ſparingly; for they are ſubject to decay when often cut. The beſt ſeaſon for lopping theſe trees is ſoon after Bartholomew-tide; at which time they ſeldom bleed much, and the wound is commonly healed over before the cold weather comes on. *Miller's Gard. Dict.*

The generality of the world are againſt pruning timber trees at all, and where they naturally grow ſtraight and regular, it is much better let alone. But all common faults in ſhape may be regulated by this lopping them while young, and it can be attended with no ill conſequence to the timber; for the cut not lying near the timber pith cannot affect it, when grown up, and ſquared in the working for beams and other uſes, or to be quartered; for all the defects occaſioned by ſuch wounds, are in the ſuperficial parts, and all the four quarters are perfectly ſound within.

As to the largeſt foreſt trees, they ſhould not be lopped at all, except in caſes of great neceſſity, and then the large boughs muſt not be cut, but only the ſide branches; and even theſe muſt be cut off cloſe, that the bark may ſoon cover the wound, and yet a little ſlanting, that the water may run off, not lodge upon the cut part.

If there is a neceſſity of cutting off a large bough, as by its being broken or cankered, let it be cut off ſlanting at about four feet diſtance from the body of the tree, and that if poſſible near ſome place where there is a young ſhoot from it, which may receive the ſap, and grow up in its place. No ſtump muſt be left ſtanding out farther than this, becauſe they are wounded parts which never can heel, and which will always be letting in the water, and will ſerve as pipes to convey that water into the heart of the body of the tree, and by degrees will utterly ſpoil it. All that grow upright, whether they be large or ſmall branches, muſt in cutting be taken off ſlanting, never evenly, for the ſame reaſon; thoſe boughs that bear from the head are to be cut with the ſlope on the lower ſide, and on any occaſion that great wounds are given to a tree, they ſhould be covered with a mixture of clay and horſe-dung, which will make them heal much ſooner than they otherwiſe would do. *Mortimer's Huſbandry, vol.* II. *p.* 91.

To LOWK, to weed corn.

LUCERN, a plant frequently cultivated in the manner of clover, and known among botaniſts by the names of medica and medicago.

It is the alfaſa of the Spaniards, and the lucern grand treffle, or fænum Burgundiacum, as ſome botaniſts call it, of the French. It has a perennial root, and an annual ſtalk, which riſes full three feet high in good land, and is garniſhed at each point with trifoliate leaves, whoſe lobes are ſpear-ſhaped, about an inch and a half long, and half an inch broad, ſawed towards the ſtalks. The flowers grow in ſpikes, which are from two to near three inches in length, ſtanding upon naked footſtalks two inches long, riſing from the wings of the ſtalks: they are of the pea-bloom, or butterfly, kind; of a fine purple colour, and are ſucceeded by compreſſed moon-ſhaped pods, which contain ſeveral kidney-ſhaped ſeeds. It flowers in June, and its ſeed ripens in September.

There are the following varieties of this ſpecies of lucern, viz. one with violet-coloured flowers; another with yellow flowers; a third with yellow and violet flowers mixed; and a fourth with variegated flowers: but, as Mr. Miller obſerves, theſe are only variations of the ſame plant, ariſing accidentally from the ſeed. However, neither the yellow nor the variegated flowered lucern, is ever ſo ſtrong as that with purple flowers; nor is it, conſequently, ſo profitable to the huſbandman.

Columella calls this the choiceſt of all fodder, becauſe it will laſt ten years, and will bear being cut down four, and ſometimes ſix times in a year; it enriches the land on which it grows, fattens the cattle fed with it, and is a remedy for ſick cattle. About three quarters of an acre of it is abundantly ſufficient to feed three horſes during the whole year. Yet, notwithſtanding it was ſo much eſteemed by the ancients, and hath been cultivated to great advantage in France and Switzerland for many years, it has not yet found ſo good a reception in England as it juſtly deſerves; nor is it cultivated here in any conſiderable quantity, though it will ſucceed as well in this country as in either of the laſt mentioned; being extremely hardy, and reſiſting the ſevereſt cold of our climate.

Mr. Rocque lays it down as a maxim in his practice, that lucern will grow on any ſoil, provided it be not ſo wet as to rot the roots.

The ſtrongeſt land is however to be preferred, and the deeper the ſoil, the better will be the crop, as the roots will have room to extend themſelves.

The land ſhould be prepared in the ſame manner as for barley, being ploughed, harrowed, and cleaned from all ſorts of weeds; and the ſtronger the land is, of courſe the more ploughing and harrowing it will take to mellow it, ſweeten it, and bring it to a fine tilth.

When this work is done, the lucern ſeed muſt be ſown broad-caſt, (not in drills) in fine weather, after the rate of about fourteen pounds to an acre.

This allowance of ſeed will be ſufficient to ſupply the number of plants that will be wanted to yield a full crop; but they will not ſtand ſo thick as to ſtarve one another, though there is ſome allowance for part of the ſeed failing.

But ſhould every ſeed take, the method of culture hereafter recommended will ſufficiently reduce the number of the plants, and, without the trouble and expence of the New Huſbandry, give each plant ſpace enough to extend its roots, and collect the neceſſary quantity of nouriſhment.

To return to the culture, before the laſt ploughing, the land ſhould be manured, not with old rotten ſtuff, as is uſual; but with freſh ſtable-dung, that has been thrown up in a heap three or four weeks to heat and ferment. This will enable the young plant to puſh forth its leaves and ſtalks with luxuriance, and get forward in its growth the firſt ſummer.

When the dung is in full fermentation, it is to be laid on the land, and ploughed in as ſoon as poſſible, that the ſalts of the dung may not have time to evaporate: the land muſt then be harrowed and ſown, and afterwards again harrowed with a light or buſh-harrow; and, laſtly, rolled to ſettle the ground and break the clods.

If corn is to be ſown amongſt it, it ſhould be only half a crop; otherwiſe it will be apt to deſtroy the lucern, eſpecially if it proves a wet ſeaſon, and the corn is rank:

but if no corn is ſown amongſt it, the lucern will thrive much better.

Lucern may be ſown from the beginning of March to the end of May; but April, in dry weather, is the beſt time.

If much rain falls on the new-ſown lucern, it will be apt to ſwell too faſt, and burſt; but if it holds fine three or four days, it will be in no danger.

Mr. Rocque does not approve of drilling the lucern, becauſe the roots are too much confined in the drills: they ſay it is to clean the lucern between the rows that they drill it; but it is for want of knowing the nature of lucern, and it diſcourages people from ſowing it, drilling and hoeing being very expenſive ways; the quickeſt and cheapeſt, and by much the beſt way, being to ſow it broad-caſt, like clover, as the roots will ſtand nearly at equal diſtances one from another every way.

Lucern requires, it is true, a great deal of nouriſhment from the earth; but there is no occaſion this nouriſhment ſhould be ſupplied by the ſurface. It is well known that the roots of lucern will run to a great depth in the ground, from whence they muſt of courſe extract a large quantity of food: this ſpares the ſurface; and in fact the land where lucern grows requires only that the natural graſs ſhould be prevented from getting to a head, which it is in our climate very apt to do, and if let alone would ſoon choke up the lucern.

It is mentioned above, that if corn is ſown with lucern, it ſhould be only half a crop: ſome of your readers may not, perhaps, readily comprehend the meaning of this expreſſion; therefore, to render it more clear, I ſhall here obſerve, that when barley or oats are to grow with lucern, a buſhel only of either, according to Mr. Rocque's method, is to be ſown firſt on an acre, then fourteen pounds of the lucern.

One thing is to be obſerved; that if the corn, notwithſtanding its being ſown ſo thin, ſhould grow ſo rank as to endanger the lucern, it will be much beſt to mow it before the harveſt, as it is better to loſe the crop of corn than to kill the lucern.

The barley, or oats, however, need not be entirely loſt, as they may, when mown, be given green to cattle; or, if the weather is fine, will make excellent hay, provided they are properly dried; and it is beſt to do it in the ſwarth, as the rich juices are in that manner leſs exhauſted. To ſow it later than May is dangerous, for fear of a dry ſeaſon, or its being eat up by the fly.

Lucern will not grow on freſh-broke up land; it muſt be tilled a year or two: peaſe and beans, for one year, will prepare the ground; but, above all, potatoes excel for ſweetening and mellowing of land; the next ſeaſon a fallow for turnips, and when the turnips are fed off with ſheep, it will greatly enrich the land, which ſhould then be prepared for lucern.

In regard to the tillage, and time of ſowing the lucern-ſeed, the nature of the ſoil muſt be conſidered. Heavy ſtrong land will require more ploughings and harrowings, and to be later ſown; light land will need fewer harrowings and ploughings, and to be ſown earlier, that the young plants may have ſtrength to ſend their roots deep into the ground, before the hot dry weather comes on to hurt them; and if, for the firſt time, the land had a trench-ploughing, it would be of great advantage.

In Languedoc they ſow no corn with the lucern; and when it is ſix or ſeven inches high, they mow it; by which all the ſeeds of annual weeds are cut off and killed.

In Normandy, the climate being much the ſame as in England, they ſow corn with it.

In Picardy, and about Paris, they ſow it, ſome with, others without corn.

At Avignon, when their lucern begins to decline, they manure the ground and plough afreſh, and ſow it with corn and lucern; and the old roots, growing again with the ſeed, make another fine crop: the ploughing will not hurt the old roots.

If a full crop of barley is ſown with lucern, and the barley grows very ſtrong, the beſt way is to mow the barley when it is in the ear.

If forward peaſe are ſown on new-broke-up land to prepare it for lucern, it may be done in one year, and turnips ſown on it as ſoon as the peaſe are off: the turnips may be fit to feed off by Chriſtmas; and as ſoon as the turnips are off, the land ſhould be ploughed, and lie fallow till a proper time to ſtir it again; or it may have a trench-ploughing, as before directed.

This method of giving land a trench-ploughing, to prepare it for lucern, is much to be recommended, as it ſtirs the earth almoſt as deep as if it was dug with a garden ſpade: of what advantage this muſt be to a plant that ſends its roots deep for nouriſhment, need not be mentioned, as it cannot but be obvious to every reader.

Was labour cheaper than it is in England, it would doubtleſs be much the beſt way to dig by hand all the land that was deſtined to lucern: many advantages would reſult from this method of tillage, and particularly the weeds and graſs would not be ſo apt to grow as in ploughed land.

I would heartily recommend it to ſome of the gentlemen in Ireland, to ſow with lucern ſome of their land that has borne a crop of potatoes; it could not fail ſucceeding, and they would have a fair opportunity of trying what crops this plant will, when beſt cultivated, yield.

I cannot but think, that on good land that has borne potatoes, there might be five good mowings in a year, particularly in Ireland, where the climate is rather milder than in England; and this without injuring the roots. An eaſy experiment would, however, ſoon make this matter known: I therefore heartily recommend it to the attention of your Iriſh readers; they are every day improving their lands, and will, doubtleſs, not ſuffer this hint to paſs unnoticed.

When we conſider the many advantages reſulting from the culture of this plant, it is aſtoniſhing that it ſhould ſo long eſcape our regard: the hint was given us by the Roman writers on the ſubject of agriculture, but we were too much attached to old cuſtoms to improve it.

In hot ſummers the ſeed may be ſaved in England, but not from the firſt growth; that being generally too rank, and ſubject to rot at bottom.

In Languedoc they ſave it from the third growth; but as this climate is colder, it will not have time to ripen, unleſs ſaved from the ſecond growth.

A dry ſoil is beſt to ſave the ſeed upon, as it is not ſo apt to grow rank; and then it may poſſibly do from the firſt growth.

As lucern, if the land is good, will bear ſeveral crops in one year, like clover; what Mr. Rocque means by the firſt, ſecond, and third growths, are, he ſays, the different crops it produces in one ſummer, which are three, four, and ſometimes five mowings, in caſe no ſeed is ſaved from it; if ſeed is ſaved, it muſt be from the ſecond growth: the ſeed will be ripe in September, and muſt be gathered by hand.

When the plants are one year old, it will be proper with a large harrow, to go over your land as often as is ſufficient to root up annual weeds and graſs.

The harrow will not hurt the lucern, the roots of it being very tough: this muſt be done in dry weather, before it begins to ſprout, which is very early in the ſpring, that the weeds and graſs may die; and if there are any patches of ground where the ſeed miſcarried, a little ſeed muſt be ſown, and the ſpot harrowed: a dreſſing with rotten dung, at the ſame time, will repay the expences of it by a larger crop: if the harrow ſhould cut or wound any of the roots, they will ſprout and grow notwithſtanding.

The ſecond ſpring, after ſowing, it will be proper to plough the ground, where the lucern grows, with a drill-plough, with a round ſhare, without a fin or feather, and without a coulter, to prevent the roots being too much hurt. It ſhould lie rough a few days to dry and mellow; then, in fine weather, be harrowed down, to mow it the cloſer.

One, not uſed to the culture of this plant, will be apt to think, that ploughing will deſtroy the lucern; but any gentleman, that will take the trouble to call at Mr. Rocque's, may be convinced that experience teaches the contrary.

To make hay of lucern, it ſhould be mowed as ſoon as the bloom appears, or rather ſooner: it muſt not be ſpread, like common graſs, but lie in the ſwarth, like clover, and turned in the ſame manner; or the leaves, which are moſt nutritive, will drop off.

If ſuffered to ſtand too long before it is mowed, the ſtalks will be too hard for the cattle to eat it, and it loſes much of its goodneſs.

The hay is good for all ſorts of cattle; and when horſes are fed with it, they ſhould not have their full allowance of corn; the lucern anſwering, in a great meaſure, the purpoſe of both corn and hay.

It is alſo the moſt profitable of any ſort of fodder to feed horſes with in the ſummer, by mowing and giving it to them green.

If the land is good, the produce is incredible; and according to the goodneſs and depth of the ſoil, ſo will the crops be.

Mr. Rocque ſays he has ſeen lucern mowed five time in a ſeaſon; yielding, at the five mowings, nearly eight loads of hay per acre.

The ſpring ploughing amongſt the lucern muſt be annually repeated: it kills the graſs and weeds, and makes the ground ferment, which promotes vegetation; and the oftener it is refreſhed with a little dung on the ſurface, the better it will pay for the trouble of cultivating it. If the dung is laid on before the winter, that the ſalts may be waſhed in by the rain and ſnow, and ploughed in, in the ſpring, it will greatly add to the profit.

This is the ſubſtance of Mr. Rocque's account of the culture of lucern; but as different ſorts of ſoil may require different methods of tillage, he has ſubjoined the idea of a harrow, with two handles like a plough, which may ſerve in light land inſtead of the plough, and will ſave ſome labour.

The teeth muſt be ſet at ſeven or eight inches apart in the firſt row, and about five inches long without the wood. The ſecond row muſt be placed nine or ten inches behind the firſt, and ſo that the teeth of the ſecond row may be againſt the ſpaces of the firſt row; and they muſt be an inch longer than thoſe in the firſt row, ſo that the ground, being looſened a little by the firſt row, the teeth of the ſecond row may go ſomething deeper; and the teeth of the third and laſt row muſt be an inch longer than thoſe of the ſecond, and placed ſo as that they may go in the ſame track with the teeth of the firſt row.

The harrow muſt be made of one ſolid piece, four or five inches thick, and the lower ſide muſt be rounded off towards the hinder part where the teeth are longeſt; whereby the perſon that holds it by the handles, preſſing down a little, may force the ſecond and third rows of teeth deeper than the firſt; and, by bearing up a little, he may prevent any but the firſt row from working. A very little practice will be ſufficient to make any one uſe it as occaſion requires; and it will be ſo ſteady that no unevenneſs of the ground will be able to throw it out of its work, as a clod or ſtone will a common harrow.

. . . . .
. . . . . } The manner the teeth are to be placed in
. . . . .

Let it be remarked, that the foremoſt row of teeth are placed in a line acroſs near the middle of the block or plank; the other two rows behind that; and the fore part of the harrow ſhould be heavier than the hind part when the weight of the harrow is ſuſpended on the firſt row of teeth. The teeth ſhould be pretty ſtrong, and round; their being ſquare, as uſual, may hurt the roots a little, which is to be avoided as much as poſſible, tho' the conſequence would not be very great.

Farmers are fond of ſowing broad-caſt, it being no eaſy matter to make them comprehend the utility of a drill-plough on any occaſion: the ſight of ſo complicated an inſtrument, terrifies them; they think it moves by clock-work: and as to the labourers, it is a very difficult matter indeed to get them to hold it.

I am fully ſenſible, as I have already obſerved, of the good effects of ſowing corn and pulſe regularly with intervals, but cannot approve of this method when applied to artificial graſſes; and it would be well if we were to improve our old practices, before we ſhould even attempt to bring the new methods into general uſe. *Muſeum Ruſticum, vol.* I. *page* 78.

In the ſucceeding volume of the above work, another correſpondent has made the following remarks on the above method delivered by Mr. Rocque.

This gentleman, ſays our author, owns he is againſt innovations in huſbandry, becauſe it is difficult to bring the farmer from the old methods; and therefore ſeems to conclude, new ones are not to be attempted; at leaſt, that ſeems to be his reaſon for being againſt what he calls innovations.

Under "reſtrictions, &c." he approves of the new culture, but thinks it "prepoſterous to extend it to artificial graſſes;" adding, "the only benefit lucern can receive from the horſe-hoe, is, that it keeps down the natural graſs." This gentleman cannot be a practical cultiva-

tor of lucern; neither can he know the uſes of the hoe-plough; if he did, he could not aſſert a fact ſo contradictory in itſelf!

To inaccurate obſervers the ſeedling plant of lucern may appear to have no lateral roots; but a careful examiner will find a great number of ſmall ones, every one, or moſt, of which are furniſhed with freſh nutriment by the operation of the hoe-plough.

We ſhall not contend about Mr. Rocque's ſuperior profit: his ſituation gives him advantages ſuperior to a diſtant reſidence; and therefore that ſhould not be mentioned by a generous writer.

I am a favourer and practiſer of the New Huſbandry; and I do deny that it will be more expenſive than Mr. Roque's method, but, on the contrary, it will eventually be cheaper.

By his method he may, for a few years, have pretty good crops; but at length his plants will be found to dwindle, and his crops will leſſen, unleſs he annually adds ſeed to the ground; whereas, in the new culture, the crop will be continually improving: as to the quality being inferior, that will be the fault of the owners, if he lets it grow too rank. This argument of your writer makes againſt himſelf, as thereby he admits the ſuperior luxuriance of the plants cultivated by the horſe-hoe.

I have ſown lucern in broad-caſt more than once, and have ſeen others do it; and it ever failed.

Mr. Rocque's rule, as this gentleman ſays, is, "that lucern will grow on any land, if not wet:" this is certainly premature: it ſurely muſt have the occupation of a dry, rich ſoil, or I am ſure, from practice, it will not ſucceed; and as to "the ſtrongeſt being preferred," I believe every one, who tries the cultivation of it on ſuch, and upon light ground, will find the latter beſt adapted to it.

But the notion of ſowing corn with lucern is quite as "prepoſterous," I think, as the new culture for it; and how a man of Mr. Rocque's famed abilities ſhould adopt ſuch a method, I am at a loſs to gueſs. Neither ſhould lucern be ſown in March, as in its infant ſtate it is very tender, and timid of froſt.

This gentleman ſays, "it is for want of knowing the nature of lucern, that they drill it." I might retort upon him; but his miſtaken zeal, I fear, will more injure the cauſe he means to promote, than I hope it will diſcourage the practice of drilling this valuable plant, as, by all men who adhere to rational principles, that hath been found the moſt ſucceſsful method. See Tull, Duhamel, &c. I ſhould be glad to know what "the furface of the ground is to be ſpared for;" is it to give life to the natural graſs, that common and deſtructive enemy of this excellent plant?

Our author mentions the cultivation of it in France, &c. If he was ever at Paris, with his preſent attention, he muſt have ſeen, that after a few years they always plough up the promiſcuous ſown lucern, in order to prepare the ground again for that, or ſome other crop, when the lucern begins to dwindle by the weeds or natural graſs robbing it of its nutriment.

How much more muſt that be the fate of promiſcuous ſown lucern in theſe kingdoms, where he admits graſs is apt to get a-head? That is not the caſe in France, and yet even there promiſcuous ſown crops are ſhort-lived.

I know not whether he be as converſant with potato-ground in Ireland as I am; but I cannot omit to inform you the tillage will not do for lucern: for this plant the ground ought to be well pulverized: whereas, in the general potato tillage of this kingdom, not more than about two feet in nine of the ground is cultivated.

The manner of harrowing the lucern, practiſed by Mr. Rocque, although the teeth be round, muſt wound many of the roots: that might be well, as it would thin them; but repeated harrowing will, in time, wound them all; and notwithſtanding they will afford graſs afterwards, yet, when the winter rain comes on, lodgments of water will be made in thoſe wounds, which will bring on putrefaction, to the deſtruction of the plants, unleſs Mr. Rocque has the art of conducting the harrow-pins always in the ſame direction; and, could that be the caſe, what would deſtroy the graſs where they did not paſs?

The manner of ploughing the lucern, practiſed by Mr. Rocque, is ſtill approaching to the horſe-hoe, tho' by no means ſo effectual. I wonder to ſee our author even favour that, ſince it may be deemed an "innovation." This ploughing is to be repeated every year, and harrowing alſo: to this dung is to be added, "as often as may be." I am willing to believe this gentleman knows nothing of the expence which attends theſe operations, *i. e.* ploughing, harrowing, and, above all, dunging, beſides the value of the dung, which would always be acceptable for other grounds; whereas, in the drill way of ſowing lucern, when the land is once put in good order, it may ever be kept ſo by the hoe-plough.

Lucern is a graſs of ſuch ineſtimable value, that it will anſwer almoſt any expence; yet if the moſt certain method to obtain ſucceſs ſhall be found the cheapeſt, there can be no reaſon for purſuing one more precarious and more expenſive, which will be found when Mr. Rocque's method, or at leaſt that ſo warmly recommended by your correſpondent, who aſſerts it to be Mr. Rocque's, is compared in practice with the one I venture to recommend to the practice of my countrymen, which I take upon me to ſay will command ſucceſs, if purſued.

The land ſhould be a flexible loam, dry, deep, and rich, either by nature, or made ſo by art; not but it will ſucceed to admiration ſhould a quarry be under. It ſhould be well pulverized by plough and harrow, laid as flat as poſſible, and cleared of all weeds, particularly ſcutch-graſs: when the ground is in this form, let a ſmall plough, with two mould-boards, be run up and down the field, at every three foot upon the flat ſurface: this will compleatly form three foot ridges. If a pair of drill-harrows be not at hand, let the crown of every ridge be carefully raked clean and even with an iron rake, and one row of ſeed drilled very thin, about half an inch deep, along the middle of every ridge, the middle or latter end of April, (the beginning of May may do) and be carefully covered. This ſowing of the ſeed may be done by hand, if a drill-plough be not ready. By a maſter's attendance, a great deal may be done in a day.

Thus it may remain till weeds begin to appear, when the hoe-plough, or a ſmall common one, ſhould take away every alternate ſide of the ridges, as near the lucern as can be with ſafety (I go within two or three inches of my drilled crops.) In three or four days, return the mould to the former places with the plough, and then proceed to take off the other ſides of the ridges in like manner, and return it as before.

If the ground be made in good condition before ſowing, a crop may be mowed in July, the produce of which

which will ſurpriſe any one who is not acquainted with the plant.

In September it will be fit to cut again; but if in the intermediate time weeds ſhould appear, let the hoeing be repeated: thus the weeds will be deſtroyed the firſt year.

After the ſecond cutting, ſend in the plough again, and take off the ſides of every ridge within about ſix inches of the plants, and ſo let them remain till February, when the plough ſhould return the mould to every ridge; and in May the graſs will be ready for cutting, and will continue to afford a crop every month during the ſummer.

The hoeing ſhould be repeated, as before directed, as often as weeds appear; but obſerve never to horſe-hoe it when the ground has any adheſion.

The hoeing before the winter is to keep the plants dry during that ſeaſon, and to meliorate the ſoil of the alleys by the influence and mechanical operation of the winter froſts.

To keep my letter within reaſonable compaſs, I have been ſhort in my directions, but to practicable farmers, I hope, ſufficiently plain; if not, any neceſſary explanation I ſhall chearfully furniſh.

Your readers will pleaſe to obſerve, that after the firſt preparation of the ground, if they horſe-hoe the crop regularly every year, the dung which Mr. Rocque's friend recommends (as it may be got eaſily at in London) may be ſaved for other purpoſes, as by this method of managing lucern, the crop and ground will be improving every year.

I appeal then to every impartial judge, whether this method is not cheaper than the ploughing, harrowing, and dunging, ſo warmly recommended by your correſpondent. It is almoſt unneceſſary to urge, that a crop raiſed in this way will, ever after the firſt year, be equal, if not ſuperior, to Mr. Rocque's, as the gentleman admits as large crops may be raiſed in the drill way.

I am a ſtranger to Mr. Rocque and his friend. I have no other motives in troubling you on this ſubject, than a public benefit to mankind, and a gratitude to the memory of Mr. Tull, whoſe ſuperior ingenuity, I bluſh to own it, hath ſhone in France, to the reproach of Engliſhmen. And were we all to join in opinion with your correſpondent (who ſays, "It would be well were we to improve our old practices, before we even attempt to bring the new ones into general uſe") we ſhould indiſcriminately merit the pity of all nations for our perverſeneſs. Perhaps, had Tull been a foreigner, his ſyſtem would have been eſtabliſhed amongſt us long ago.

The author of the former account not being ſatisfied with the reaſons offered by his antagoniſt, made the following reply; which we thought neceſſary to inſert, that our readers may judge for themſelves, and follow the method that ſhall appear to them the moſt rational.

I troubled you the beginning of laſt year with a letter on the ſubject of lucern, which you were ſo obliging as to inſert in your firſt volume, page 339.

I am ſtill an advocate for Mr. Rocque's method of culture in preference to Mr. Miller's, as far as regards this plant; and that for this plain reaſon, becauſe I imagine the farmer will be much more likely to adopt the firſt than the laſt; and the culture of lucern can produce very little advantage to the nation, unleſs it is generally adopted by the common farmers.

My reaſon for troubling you, or your readers, at this time, is to remind you, that Mr. Rocque's ſmall tract, lately publiſhed, contains ſome particulars reſpecting lucern, which were not noticed in my former letter, and therefore may, with great propriety, be now laid before your readers.

The firſt of theſe particulars relates to the manner of ſowing the lucern; and in this Mr. Rocque differs widely from Mr. Miller, as he thinks it ſhould not be ſown without corn; but I will give you Mr. Rocque's own words, as they carry great weight with them. "You muſt not ſow lucern without corn, unleſs your ſpot of land is too ſmall to uſe a harrow in: in that caſe, you muſt ſow it in drills, and keep it very clean hoed. The drills for ſuch ſmall ſpots are to be ten inches diſtant; if wider, it lodges in the drills. The reaſon I recommend ſowing corn with it, is, to prevent the weeds choaking it; but, you muſt ſow only for half a crop; otherwiſe your corn will be apt to deſtroy your lucern, eſpecially if it proves a wet ſeaſon, and your corn is ſtrong. If there is no corn ſown amongſt it, you muſt be obliged to mow the weeds, and run a chance of cutting the lucern with them: and, being very ſappy, you cannot imagine how detrimental it is to bleed it, when young; but, when the corn will be fit to mow, the lucern alſo may ſafely be cut."

As the duration of lucern has been a queſtion long agitated, and not, that I know of, finally determined, it will not be amiſs to mention a fact related by this able cultivator, as it will be an encouragement to the planters of lucern.

"As to the duration, it will laſt as long as the ground is kept clean. I ſaw ſome at Mr. Middlemar's, at Grantham, in his garden, that was forty years old; and it was very fine. To keep it thorough clean, you muſt harrow it every time it is mowed; and, if requiſite, at Michaelmas, and in February and March. If you once leave it foul, it will be very expenſive to clean. You muſt make uſe of the drill-plough: but let the harrow be ever ſo ſtrong, you need not fear its hurting it."

In my letter to you, above-mentioned, it is obſerved, that in preparing land for lucern, a trench-ploughing would be of great advantage: but in the piece lately publiſhed, Mr. Rocque ſays, "In caſe you are not well acquainted with the ſtate of your ground, you muſt trench-plough it twice, according to the directions for ploughing, which are in my Hints upon Burnet; whereby the roots will run down the ſooner out of the reach of dry weather: and if the ſoil, that is turned up, be ever ſo ſour, future ploughings, harrowings, and manurings, will ſweeten it ſufficiently for the reception of the ſeed."

Mr. Rocque adds, in this place, that "Lucern will grow very well in clay land, with proviſo the ground works well. The difficulty in theſe lands lies in the harrowing; in dry weather the ground being ſo very hard, the harrow can do but little good, unleſs you take the ſeaſon between wet and dry to harrow it, which you certainly muſt."

It is alſo obſerved, that in the province of Languedoc, in France, the inhabitants mow their lucern when it is ſix or ſeven inches high, in order to kill the annual weeds. Of this practice Mr. Rocque now ſays, "By my own experience, I find they are in the wrong; for it bleeds it, ſo that the plants make but little progreſs when cut ſo young, and are a long time in recovering it. It ought never to be cut but when in bloom."

A great many imagine that the ſeed might profitably be ſaved in England; but Mr. Rocque is of a different opinion.

opinion, and indeed I am inclined to join with him in this reſpect, as in this iſland it is at beſt but a precarious crop, and can be imported ſo cheap, that the ſeedſman can afford to retail it at nine-pence per pound, at which price it was this year advertiſed. Mr. Rocque's obſervation on this point is as follows: "In hot ſummers the ſeed may be ſaved in England, but not from the firſt growth, that being generally too rank, and ſubject to rot at bottom: though I think it is needleſs attempting to ſave any of the ſeed in England; for, in the year 1761, which was a very fine ſummer, I tried to ſave the ſeed of the ſecond growth, on light land, but made nothing of it; not ſaving above thirty pounds of ſeed, upon four acres and a half. I alſo tried, that ſame ſummer, to ſave ſome off ſtiff land; but that proved ſtill worſe."

I have only now to give you Mr. Rocque's thoughts on the value of this graſs, which, in my opinion, deſerves to be preferred to almoſt all others.

This practical cultivator ſays, "I have already obſerved, it ought not to be cut but when it is in bloſſom; and that is but three times a year: but after mowing the third crop, you may, inſtead of mowing the fourth, ſeed it: but when froſts come, you muſt take your cattle off; becauſe there are always young ſhoots, which would be bruiſed, if the cattle were not taken off. If it is rank in September, it is dangerous for cows, being too feeding; but turn horſes and ſheep upon it. As there is no graſs, as has yet come to our knowledge, which gives the cows ſo much milk, you may let them graze about an hour, at moſt, in the afternoon, when the dew is off. When made hay, it is likewiſe the beſt for milk: wherever it is much cultivated, they prefer it to all other kind of hay.

When I was at Monoſque, a city in Provence, which was about twenty-ſeven years ago, the carriers fed their horſes upon it, preferably to any other, without corn; and the mules looked fat and in fine order. Six mules which I hired there, to carry my ſeeds at Nimes, fed on nothing elſe, and yet carried their load all day long, without unloading. They have the cuſtom of hanging little bags to their horſes or mules heads, wherein they put lucern, on which they feed as they go.

It is acknowledged by all connoiſſeurs to be the moſt feeding of all paſture, either green or in hay. I truſt not barely to report, but have experienced it to be ſo myſelf. I had colonel Vernon's horſe ſent to me from the country, in a very poor condition; and, in fourteen days, he was in very good order. The colonel was ſurprized to ſee how he had throve in that ſhort ſpace of time.

Many are apt to condemn it, but it is for want of knowing its good qualities. It has been introduced for a long ſeries of years; but ſo little noticed, that one and twenty years ago there was not two hundred weight of lucern graſs ſeeds to be ſold amongſt all the ſeedſmen here in London; and I had much ado to re-introduce it; but now, within theſe three or four years, there is a prodigious conſumption of it.

One Mr. Beadle, a farmer in Kent, has fourteen acres of it, for which he had a premium. When I called upon him, which was in the beginning of May laſt, he had mowed his lucern, and ſold it upon the ſpot, for three pounds or three guineas a load. I blamed him for cutting it ſo young; but he told me he was compelled to it, to get fodder for eight hundred head of ſheep, that he had; but that, a little while after, it grew ſo faſt, that he could turn his ſheep upon it. Thoſe that bought his hay muſt needs be well acquainted with the goodneſs of it, to fetch it on the ſpot, though they were ten or twelve miles diſtant.

It is not foggy, like clover or tares. Horſes will work with it green, as well as with hay or corn: they do not ſweat with it, as they do with other green fodder. I have been told, one of our poſt-maſters kept his horſes both winter and ſummer with it, and that his horſes were the beſt on the road. They object, the hay of it is difficult to make: it is no more difficult than clover. All hay is difficult to make in wet weather: but when it is a bad ſeaſon to make hay, do as Mr. Allen does; put it up in ricks when dry, and between every bed of hay, of any kind, put a layer of ſalt, and that will recover all the damage the rain can have done.

I have done it myſelf, this very laſt year, with a rick of burnet: to about twelve loads I have put a ſack of ſalt amongſt it; and every time my horſe comes near it, he eats it very eagerly, though he can get but at the outſide of it. It will keep in ricks as long as any hay.

Multitudes, at preſent, are pretty well acquainted with the excellence of both theſe graſſes: but if any doubt the truth of what I aſſert, let them take the trouble to enquire into it, of Mr. Shennelly, the tobacconiſt, at Houndſditch; to whom I have ſent a load of lucern, and am to ſend another load of the ſame, and half a load of burnet hay.

Thoſe who are not ſatisfied with the theory, may be convinced of the practical part, by ſeeing a field of mine of lucern, of four acres and a half, at Batterſea, and the manner of working the harrow."

From what has been ſaid on the ſubject of lucern, I hope your farming readers will be induced to adopt the culture of it; as, if they are not blind to their intereſts, they cannot but be convinced of the many advantages which would reſult to them from ſo doing. Mr. Rocque's method of cultivating this plant differs but little from the manner in which they raiſe clover; and the profit to the landholder will be abundantly greater. *Muſeum Ruſticum, vol.* iv. *p.* 259.

The following method of cultivating lucern, is extracted from a very ingenious performance, entitled, *Eſſays on Huſbandry*, the principal intention of which is to recommend a newly diſcovered method of cultivating this plant.

Mr. Rocque, as may be ſeen above, has adopted the old Roman method of ſowing it, broad-caſt, and harrowing the land from time to time by way of deſtroying the weeds. Mr. Miller recommends the new, or drill, huſbandry for the culture of lucern; but the author of the Eſſays above-mentioned differs from both theſe practical cultivators, and raiſes his lucern in a nurſery; after which he removes the young plants, and having cut off their ſtalks and tap roots, tranſplants them, with great regularity, into the field where they are to ſtand for a crop.

I ſhall not pretend to decide which is the beſt method; yet I may venture to ſay, that I know it may be raiſed to conſiderable profit, both in Mr. Rocque's way, and according to the rules laid down in the new, or horſe-hoeing, huſbandry.

I have no doubt but it may ſucceed by tranſplantation; yet I greatly fear that the expences in this method will when applied to any conſiderable extent of land, greatly exceed the worth of the crop. Theſe

Theſe Eſſays being too learned for the honeſt farmer's reading, it is very improbable they ſhould ever fall into his hands; yet, as it is a great pity he ſhould not be permitted to judge for himſelf in a matter which may turn out ſo much to his advantage, we have taken the trouble of tranſcribing a few pages of the ſecond Eſſay, which more immediately treats of the culture of lucern by this new method of tranſplanting.

In this extract we have omitted all reaſonings that might render the narration obſcure to the farmer; not that we had ourſelves any objection to them, or did not approve of them, but that we were willing the honeſt cultivator ſhould have as much of this matter laid before his view, in a plain manner, as was neceſſary for him to underſtand it: when this is done, he may judge for himſelf; and if on trial he finds the method here recommended anſwer, his beſt way will be to adopt it in his future practice.

Whoever propoſes to ſow a lucern-nurſery, or engages in any larger undertaking of cultivating whole fields of ſainfoin, trefoil, buck-wheat, ſpurrey, fenugreek, ſweet melilot, &c. would be no ways ill-adviſed, if he prepared a bit of ground, and ſowed a ſpoonful of the ſeeds about a fortnight before he propoſed to ſow his larger quantity; ſince, from the good or bad ſucceſs of this little attempt, he may be enabled to judge, whether the ſeedſman has ſupplied him with ſeeds fit for vegetation. Without ſuch precaution, a whole year may be loſt; which is a mortifying circumſtance in matters of huſbandry.

In the end of March, 1757, a common day-labourer was ordered to ſow a pound and a half of lucern-ſeed, and keep the ground clear from weeds. The ſeed was ſown on one of the leaſt promiſing pieces of land in all the neighbourhood; but this was done by expreſs order; for it was thought unfair to make the experiment on a better ſoil than the commoneſt ſort of graſs-fields. The ſpot of earth ſet apart for the purpoſes, both of nurſery and tranſplantation, was, in former times, a kitchen-garden: but the good ſoil, to the depth of eighteen inches, had been removed for the ſake of manuring a corn-field. [To which we ſhall juſt add, that the attempt was made in an hilly country, where the ſtaple earth is naturally ſhallow.] What remained was a cold, yellow, clammy ſtratum, which the country people looked upon as mere clay; but, its nature having ſince been better examined, it appears to be a mixture of imperfect clay, and imperfect marle. No manure worth mention was uſed upon it, as will appear by the ſequel.

To all ſeeming appearance, little, or next to nothing, could be expected from a piece of ground of ſuch an unpromiſing caſt; but, upon the whole, the experiment proved ſucceſsful and eaſy.

By the middle of Auguſt, the plants were, ſome of them, eighteen inches high; and many of them branched out, ſubdivided themſelves, and made very fine ſide-ſhoots: upon which it was reſolved to venture upon the ſecond part of the experiment, according to the accounts given by M. de Chateauvieux; therefore taking the advantage of a moiſt ſeaſon, in the beginning of September, (which ſeaſon, by the way, did not laſt long) we performed the work in the following manner. But here let it be juſt obſerved, in paſſing along, that the time of the year, pitched upon for tranſplanting, was, at leaſt, three weeks too late for England, though, perhaps, highly proper for the territory of Geneva, or the ſouthern parts of France. This therefore is ſet down as one of the *mutatis mutandis* ſo indiſpenſibly neceſſary in matters of agriculture, when the practice of one country is copied in another.

Firſt the roots were dug up carefully; orders being given before-hand not to attempt drawing them, even with the ſmalleſt degree of violence, till the earth was entirely looſened at top and at bottom. In the next place, the long tap-roots were cut off eight, nine, or ten inches, diſcretionally, below the crown of the plant (the ſciſſars being generally applied juſt beneath the forks of the root, if it be a branching root:) then the ſtalks were clipped about five inches above the crown of the plant; and the remaining plant, after theſe amputations, (which may appear, at firſt ſight, to be very bold ones) was thrown into a large veſſel of water which ſtood by for that purpoſe, in the ſhade. Such refreſhment is no ways unneceſſary; for this plant is very impatient of heat and ſun-ſhine after it is taken up; nay, to ſuch a degree, (at leaſt the firſt half year of its growth) that one may almoſt call it a ſenſitive plant. The ſame day, making uſe of a dibble, or ſetting-ſtick, and filling every hole with water before the roots are put in, we tranſplanted them in rows, two feet aſunder, and each plant ſix inches apart in the rows; having firſt made little drills, or channels, and ſprinkled, or half filled, them with ſea-ſand and wood-aſhes kept dry (two parts of the former to one of the latter;) which was done with a view of looſening the ſoil, and giving a little warmth to a piece of ground which was naturally cold and clayey; nor was any other manure uſed. The drills were afterwards once watered, to take off the dryneſs and heat of the aſhes. The roots were placed firmly in the ground, and two inches of the ſtalks covered with mould.

Yet here it muſt be freely acknowledged, that the hopes of poſſeſſing a large crop occaſioned one miſtake, which we chooſe rather to mention than ſuppreſs, as many people may happen to entertain the ſame falſe expectances. The miſtake was that we made our rows two feet aſunder, which was over-narrow; and placed the plants, in the lines, only ſix inches apart, which brought them nearer together than they ought to have ſtood, even though the ground was very poor: nor did we foreſee, that horſe-hoe ploughing is five times more efficacious, as well as cheaper, than hand-hoeings.

Therefore, after frequent experiments, ſince made, it appears beſt to make the lines three feet four inches diſtant from each other: and if the ſoil be good, it may not be amiſs to allow each plant a foot diſtance one from another in the lines, for thus the hand-hoers will work more commodiouſly, and a little hoe-plough may be guided ſafely up and down the intervals, which will ſave a great deal of trouble: nor will the future crops be leſſened, by ſuch thin tranſplanting, half ſo much as may be imagined; but, on the contrary, the plants will be larger, more juicy and better taſted; which circumſtance may be extended in favour of the New Huſbandry in general. Space and culture improve the herbage and ſeeds of plants; in proof whereof I have been aſſured, from good authority, that all the corn, raiſed by M. de Chateauvieux, ſells at an advanced price; being larger, brighter, and healthier than common corn, and, conſequently, more fit for ſowing, or making bread.

But, by way of confirming the neceſſity of allowing lucern roots a good ſhare of ſpace, a friend of the author's filled an acre with plants, according to the firſt directions; but, the ſoil proving extremely good, and free from weeds, it

it ſoon appeared that the roots ſtood too cloſe: in conſequence whereof, every other plant was taken up the next autumn, and, a freſh acre of land being properly prepared to receive them, he thus gained a new plantation of lucern, at a ſmall expence, with little trouble: and, what is more remarkable, it is thought the ſecond acre bore a larger quantity of herbage than the firſt would have done, if the plants had continued as they were, without being thinned, to the amount of one half. Of courſe, there is reaſon to conclude, that this ſlight hint, which took its riſe from mere accident, ought not to be looked upon as quite unuſeful, ſince two acres may be raiſed with almoſt the ſame expence as a ſingle acre.

In ten days, though a drought ſucceeded, ſome tranſplanted plants made ſhoots of three inches height; which vigorous growth gave better hopes than had been conceived at firſt.

It was alſo ſome encouragement to the undertaker, that he found wild lucern within two muſket ſhots of the place where the nurſery was formed. Theſe plants were certainly *aborigines*; for they grew in a part of the kingdom where the name of lucern had rarely been heard of, except by gentlemen. Beſides, no perſon curious in huſbandry would have ventured ſowing the ſeeds in ſuch an unpromiſing piece of ground; for the field, where the wild lucern grew, was a ſort of coarſe, uncultivated moraſs, and valued only at about two ſhillings and ſixpence an acre.

Yet ſtill the approach of winter made many perſons doubtful concerning the ſucceſs of this new plantation; nevertheleſs, it was ſome ſatisfaction to recollect, that there is leſs harſh, ſevere cold in England (and that almoſt by one third) than in the territory of Geneva, where the original experiment was made, and where the plant we are ſpeaking of has been known to thrive ſo extremely well.

At length the winter paſſed over, and, out of four thouſand roots, only thirty or forty periſhed, whether by froſts, immoderate rains, or any other accident, is hard to ſay: but the labourer filled up all the vacant ſpaces from the nurſery in about an hour, and in April, 1758 moſt of the plants were nearly equal in ſize and ſtrength; of a deep juicy verdure, with few or no diſcoloured ſickly leaves: but, May the eighth, people counted ſixty ſtems from one particular root, and the ſtalks and leaves of ſome choſen plants weighed near half a pound at one cutting. Yet we learn, by experience, that lucern muſt only be conſidered as in a progreſſive ſtate, till the third ſummer after tranſplanting; and then M. du Hamel aſſures us, that one flouriſhing plant will produce a pound of well-dried hay; which is ſaying a great deal, and much more than I could ever verify; for if a ſingle plant produces one pound of hay, it muſt have weighed four pounds when it was green. Yet I have received an account from an eminent phyſician in our own country, (who planted two acres of lucern by my directions) that many of his plants, in the ſecond year, yielded near half a pound of hay each plant.

As an acre of lucern, thus managed, will contain more roots than one is apt to imagine at firſt gueſs, how great muſt the produce be of four or five cuttings every year, and thoſe confeſſedly the moſt nouriſhing and palatable food that cattle can eat! For thus much is certain, amongſt other advantages, that, if a field be induſtriouſly hoed, ploughed in the intervals and ſpaces, and hand-weeded in the rows, for the firſt two or three years, it is almoſt ſure, that horſes, cows, or ſheep, will hardly find a ſingle weed in a large quantity of green food.

We will now mention the ſtate of our tranſplanted lucern in its ſecond year, namely, 1758.

And here let it be remembred, that what cultivators call a proper time for cutting is, when the plants are about fifteen or ſixteen inches high, at an average, throughout the field: but this muſt be underſtood in a relative ſenſe, for ſome plants will be two or three feet high, and others may not be above ten inches, or one foot, in height, according to the circumſtances of health, ſpace, ſituation, &c. of the ſeveral roots.

The cuttings of the year 1758 were as follows: May 8th, June 7th, July 12th, Auguſt 20th, and October 1ſt.

In the year 1759, it was cut five times, and ſix times in 1760; which made ſixteen cuttings in three years. Nay by the ninth of April, in 1760, ſome of the lucern plants were near ſeventeen inches high, at a time when no field in the neighbourhood had graſs of four inches height, though you took five or ſix acres together. The ſame lucern was cut twice, before any hay-making began in the country round it, if we except ſome few meadows lying near market-towns.

Having carried on my firſt experiment thus far, upon almoſt as unpromiſing a piece of land as could be found, and being ſenſible I had made ſome miſtakes from want of experience (having as yet never ſeen any tranſplanted lucern in England) I gave directions for making a ſmall plantation in Berkſhire, but ſtill took care to chooſe a field that could hardly be called middling land. It was overrun with coarſe weeds, had been long out of tillage, and the earth in moſt places, was hardly four inches above a bed of chalk; which (let farmers ſay what they pleaſe of it, in reſpect to ſaintfoin) is no ways favourable to the growth of lucern, eſpecially if the latter be tranſplanted; for the chalk flakes, when thaws and rains come on; and it either heaves the plants out of the ground, or expoſes the fibres of the roots too much to the cold. Yet upon this I ventured with my eyes open; for Pliny (whoſe authority I ſcruple not to take, when I have no other) had given me a caution concerning lucern raiſed upon chalky lands: but what induced me to make the attempt was, that the goodneſs of the ſoil might not lead me to ſay more concerning the ſucceſs of an experiment than other people may hope to find.

The little field, or cloſe, conſiſted of one rood of ground, or a quarter of an acre; which we threw into fifty-four rows, each row containing one hundred and ten plants, or five thouſand nine hundred and forty in the whole. In the ſecond year after tranſplanting, (and lucern is not then arrived to its due ſize) and at the firſt annual cutting, (which is not the beſt cutting, as the herbage ſuffers much from the winter) I weighed, out of curioſity, a parcel of the prime plants, which one with another, weighed about one pound and a quarter each. But ſuppoſing that every plant weighed only one quarter of a pound, and admitting we give up the ſixth cutting, (which is more than one needs to do) then the crop of forty perches, or one fourth of an acre, amounts to a very conſiderable return of ten tons, at leaſt, of green lucern per acre.

An acre of tranſplanted lucern, rightly managed, will bring in five pounds a year, free and clear from all expences,

pences, and that for a conſiderable tract of time. Now certainly this advantage deſerves well to be conſidered; for the huſbandman is ſaid to be a good manager who makes three rents each year; a firſt for the landlord, a ſecond for labour, &c. and a third for himſelf: but an acre of lucern will for ſeveral years produce five rents, clear of all out-goings for rates, rent, workmen, manure, &c. ſuppoſing the land to be let at fifteen ſhillings an acre, as uſually happens in moſt eſtates that lie at ſome diſtance from cities and market towns. On the contrary, if land be dearer near rich populous places, the ground will be better, and the produce more advantageous. This gives lucern its value near towns and cities, where two or three acres may be rented, but ten or twenty cannot; and ſure it is ſome advantage in huſbandry to make one acre ſupply the place of two or three, and eſpecially where it is difficult to rent land, even at a very high price.

It is certain, that the profits ariſing from tranſplanted lucern have been no ways exaggerated in my account; for by ſome collateral obſervations, it may be eaſy to carry the value of an acre ſomething higher than has been here repreſented. Suppoſe green vetches (which are rarely cut more than once) and green lucern to be of equal value as food for horſes (which is making a ſuppoſition no good writer in Huſbandry will allow to the advantage of lucern;) now a perch of green vetches (if the crop be good) ſells for ſixpence at ſeventy miles diſtance from London, and a perch of tranſplanted lucern will weigh as much, or very nearly as much, at two cuttings, out of the four or five annual cuttings; which (every circumſtance being duly conſidered) brings an acre of lucern (to ſay the leaſt of its advantages in huſbandry) to be of equal value with two acres and a half of vetches; not to mention that lucern is a perennial plant, and vetches are annual; which, upon the whole, makes a new difference in point of profit.

As I think it unfair to ſuppreſs any unſucceſsful circumſtances in matters of huſbandry, I will here ingenuouſly confeſs, that the moſt material of my miſtakes were theſe: I followed my foreign inſtructions (which, at that time, were but few) with too much diffidence, and in too literal a manner. I was not enabled, through want of experience, to adapt the huſbandry practices of other nations to the Engliſh climate. I tranſplanted too late, filled my rows too full, and allowed not ſufficient ſpace for the intervals. By following the French directions over cloſely, I cut the tap-roots too ſhort in the beſt plants, and knew not (as it is a point unmentioned by any cultivator of lucern) how to manage a root that was very ſmall. The means of avoiding and rectifying all which miſtakes and difficulties are, by the help of ſubſequent experience, carefully pointed out.

And here it may be worth conſidering how to apply a field of lucern, carefully and induſtriouſly cultivated, to the greateſt advantage. In ſuch a caſe, let us ſuppoſe the plantation to conſiſt of two acres, and that four large horſes are to be ſupplied with green fodder, from the end of April till Michaelmas Now, in order to manage this affair with dexterity, count the number of rows or lines in the lucern field, and place in one of the head-lands thirty land-marks, at equal diſtances; and thus, having cut a proper portion, day by day, you will be ready to begin afreſh, after the laſt cutting.

When I ſay you will be ready to begin afreſh at the end of thirty days, I muſt deſire to be underſtood, with a ſmall degree of latitude: for phyſical accidents are ſo numerous and unavoidable in regard to the growth of plants (though lucern is liable to fewer checks and miſcarriages than moſt other cultivated field vegetables) yet ſtill the nature of the thing will not allow us to predict the time of each and every periodical cutting with much certainty; nevertheleſs, thus much may be depended upon, even for ſome years ſucceſſively, that, after the firſt annual cutting, our directions, here given, will be attended with no inconvenience to the owner; for there will rarely be more than three or four days difference between the times of the ſecond, third, and fourth cuttings: nor will the want of lucern fodder, during ſuch ſhort intervals, be of the leaſt ill conſequence; for, ſurely, that huſbandman muſt be a very improvident manager who has not other graſs fields by way of a momentary ſupply.

The times, therefore, of the ſecond, third, and fourth annual cuttings, are tolerably certain; but the firſt cutting, according to the nature of the winter, may be accelerated, or retarded, a fortnight, three weeks, and, perhaps, a month.

The time of the fifth cutting is alſo, in ſome degree, variable and uncertain, as the ſolar heat decreaſes, and the days grow ſhorter. A ſixth cutting, which is ſeldom of much conſequence, chiefly depends on a fortunate ſeaſon, in conjunction with the induſtrious good management of the cultivator.

From this ſucceſſion of freſh green food appears one ſingular advantage in raiſing lucern: and in the next place care muſt be taken, that your plantation be always proportionable to your number of cattle; or, in other words, let it be a rule to you to have rather over much lucern, than too little; for then one cutting may be ſet apart for hay, which may be given occaſionally to favourite horſes and ſick cattle. But, in caſe no hay is made, the owner of the ground, even then, by means of the ſupplies he derives from green lucern, will be enabled to ſpare a large quantity of other graſs for hay-making; and thus two acres of lucern will give him the power of ſaving two or three tons of hay more than he could have ſaved otherwiſe; conſequently lucern, in effect, helps to keep cattle both in winter and ſummer.

By ſuch ſort of huſbandry, and provident management, the ſtock of hay for winter will be conſiderably increaſed, and the owner enabled, for the ſpace of five months at leaſt in the other parts of the year, to allow his horſes very nearly the ſame quantities of green food each day; all equally freſh, wholeſome, and well taſted: which ſingle circumſtance, (if it related to horſes only) gives lucern the preference over all other ſorts of green fodder hitherto known, and in proceſs of time may be applied (as has been experienced with much ſucceſs) to the fatting of horned cattle, provided ſuch cautions are uſed as ſhall be ſpecified hereafter, and which ought always to be remembered. Now whatever increaſes the number of cattle, augments the quantity of dung neceſſary for carrying on the more ſucceſsful cultivation of arable lands; and whatever, by multiplying the number of cattle, affords more animal food to man, will of courſe contribute towards leſſening the price of meat, which will aſſiſt ſociety in general, and more particularly the manufacturer and peaſant; for the grand ſecret of well managing a trading populous country is to ſupply the inhabitants with fleſh and corn upon eaſy terms; for then mankind will multi-

ply of courſe (ſuppoſing the government to be mild and equal;) nor will other nations underſel us in the commodities we export to foreign markets.

Now lucern, in matters of huſbandry, comes the neareſt of any article yet known, towards attaining the points here propoſed; foraſmuch as one acre of land, thus cultivated, will ſupport as many cattle in ſpring, ſummer, and a part of autumn, as four acres of common, natural, upland graſs did before. But this uſe of lucern is greater, if land be ſcarce; or if the nation be populous, and the ſoil has been cultivated to the extent of the old huſbandry: for then the introducing this plant is, in effect, the ſame as creating new land, if the ſuperior produce of lucern, both in quantity and quality, be fairly conſidered by us.

Yet one thing muſt be well underſtood in the new practice of raiſing lucern. Negligent huſbandmen, and ſuch as expect good crops without labour, expence, frequent ploughings, weedings, &c. would act a wiſe part in not attempting to cultivate the plant here mentioned: nor is it adviſable for gentlemen of fortune to commit this part of huſbandry to bailiffs and ſervants, who (be their maſters advantage ever ſo great) will not like the labour (though they were well paid for it) of turning fields into a ſort of gardens, and, beſides all this, may conceive a prejudice againſt improvements, and take ſome ſmall delight to ſee them miſcarry: ſo that all random, careleſs, and inſincere methods of culture muſt have nothing to do with raiſing plants, which, though hardy and long-lived after they attain a certain age, yet are ſurpriſingly delicate and tender when they are young, or when firſt tranſplanted; and more eſpecially if wild couch-graſs and other weeds ſhould ſpring up amongſt them.

For theſe reaſons, at firſt ſetting out, I muſt adviſe every good cultivator to be particularly induſtrious in the extirpation of weeds, and that he over-burdens not the ſtrength of the earth from a principle of avarice, but allows her the juſt refreſhments of manures, and gives her at leaſt ſome breathing ſpace of eaſe and repoſe.

It is highly unreaſonable to expect ſucceſs in the management of this plant without care, and highly improbable (if the ſeeds are good) to miſcarry with due care. It is true, many people have failed in the proceſs of this experiment; but then one is generally enabled to point out the error, as likewiſe the cauſe of ill ſucceſs, with tolerable exactneſs. To begin well in cultivating this plant is doing but little; rules and directions muſt be cautiouſly obſerved for three, or two years at leaſt. Few people make miſtakes in the beginning of an experiment: but, generally ſpeaking, after three or four months are expired, the maſter's attention and keenneſs wear off, and the bailiff or gardener, (as ſometimes the raiſing of a lucern nurſery falls in the province of the latter) are extremely glad not to refreſh his memory: for the ones does not like an additional trouble out of his department (a punctilio which has great weight with all ſervants;) and it is a maxim with the other, never to admit any thing new in matters of huſbandry, but admire thoſe ſorts of crops which Columella deſcribes, crops that can hold up their heads, and proſper under all the negligence of a pretending cultivator.

It is true, many difficulties and diſcouragements attend making experiments. The continuance of life is as ſhort as that of art is permanent; and few huſbandry experiments can be made oftener than once in a year: nor muſt we reaſon too much by analogy, from ſucceſs in one production, to ſucceſs in another of a different ſpecies. Attention alſo is required, and that even to the minuteſt circumſtances: and again, too many experiments die with the obſerver; which, though highly uſeful, did not appear conſiderable enough for human vanity to eſtabliſh a ſyſtem thereon.

Yet ſtill all theſe difficulties and diſcouragements may be counter-balanced by the advantages which reſult afterwards to ſociety.

Lucern cannot eaſily be freed from manifeſt diſadvantages by any other method of culture than what is here recommended. That it has uſually miſcarried, when ſown with ſpring-corn, after repeated trials in this kingdom, from the year 1577 to 1764, is well known to many readers; for common wild graſs, and particularly couch-graſs, may be called its deſtruction, if not its poiſon, principally indeed by ſtarving the roots of it, but probably from its effluvia too. This likewiſe I have always obſerved in plants of a different ſpecies that ſtand too near each other; they immediately, as it were by a declaration of war, contend for maſtery: the roots are conſtantly attempting depredations and encroachments upon each other; whilſt the ſtalks, eſpecially thoſe of weeds, make the ſame efforts in longitudinal ſhoots; and that plant, which over-tops the other, provided the ſhoots are equally thick and ſtrong, always gains the victory, and, by overſhading and dripping upon its antagoniſt, forces it to dwindle away and periſh. This ſtruggling for life and maſtery draws up the plants too weak and ſpindling, and the conquered plant uſually dies. Now weeds, generally ſpeaking, are more hardy, ſavage, and hungry, than manured vegetables. If ſuch be the caſe, where is there a country to be found that abounds with foul graſs and weeds more than England? So that, if lucern be ſown in the uſual way amongſt corn, like ray-graſs, clover, and hop-treſoil, no care can keep an acre clean. It may laſt two years, (only one crop being tolerable) and then muſt periſh in the common courſe of nature. A gentleman very lately made this experiment (in good meaſure againſt his judgment) for the ſake of farmers, in hopes of finding out a cheap, eaſy, and compendious method of raiſing lucern; but the crop at the end of fifteen months, was as near being overpowered and ſtarved as can be imagined; which made him venture to take up and tranſplant the few good roots that remained, which, being freed from the bad neighbourhood and incumbrance of coarſe graſs and other weeds, appeared to proſper very well. Again, if lucern be raiſed in drills, according to the beſt directions hitherto given by our ingenious countrymen, Tull and Miller, (who, to do them juſtice, were the firſt perſons, amongſt our modern writers, that ſaw the great advantage of this graſs, and preſſed the culture of it ſtrongly on the Engliſh nation) certain it is, that ſuch a method will greatly exceed the promiſcuous ſowing of lucern with ſpring-corn. Yet ſtill, in the practice of drilling, a conſiderable part of the ſeeds may be faulty, and then the rows will appear naked and unſupplied with herbage: nor can the hopper be ſuppoſed always to drop the little grains at preciſe diſtances plant from plant. Nevertheleſs, ſuch perſons as prefer drilling may fill up all the vacant ſpaces with tranſplanted roots.

In the method of cultivating lucern, which is here recommended, an acre will be found to contain about ſuch a number of choſen healthy roots as the ground is capable of

of ſupporting, and admit a greater number of them than the reader will be apt to imagine, *prima facie*; for it will hold, according to my firſt experiment, about twenty-ſix thouſand plants: but, if the ground be clean, rich, and well conditioned, it may be more adviſable to obſerve the greater diſtances already mentioned; upon which principle, the acre will contain about thirteen thouſand plants; and this is the number, all things conſidered, I am moſt inclined to recommend; for the produce of ſuch an acre will be full as large and profitable as the former, and the ground will be managed with leſs expence and more convenience.

It may be obſerved farther, that, in tranſplanting lucern, there will be one advantage (and that no ſmall one) which can never be obtained in drilling, or promiſcuous ſowing; each root will ſtand at a proper diſtance from its neighbour, and receive its allowance of food in due quantity, without diminution. In the next place, you will ſeldom ſee a plant wanting, and rarely (except by miſtake) a plant ſupernumerary: but, if a few ſets ſhould chance to die, it will be eaſy to ſupply the vacant ſpaces from the nurſery, and that, as people find by experience, in any moiſt day, from April till the middle of September.

There is another advantage which ariſes from tranſplanting lucern; for, by cutting the tap-root, you prevent its penetrating ten or twelve feet perpendicular into the ground, which the plant naturally does in three or four years, except it be obſtructed by a ſtratum of rock, or chilled at root by weeping ſprings, or finds admiſſion in a bed of cold watery clay. Then the crop makes a poor appearance, or, perhaps, goes off all at once.

People who hand-hoe or horſe-hoe lucern, need not give themſelves much pain about breaking or cutting off a lateral root accidentally; not but that ſome care and caution muſt always be uſed: however, what ſeems to injure the parent-plant proves, in the end, no-ways diſadvantageous to it: for horizontal, or ſide roots, thus cut, or broken, puſh forth new roots and filaments laterally; and thus the ſuckers, or tubes that ſuck nouriſhment, are multiplied by a cauſe which had the appearance of leſſening their number. Yet tranſplanted lucern will no-ways bear ſuch rude treatment as the antients ſometimes gave to untranſplanted lucern, when they thought fit to make it undergo the diſcipline of harrowing.

How long lucern may laſt cannot be known by the experiments which are here related, namely, from the ſpring of 1757 to the beginning of the year 1764; but ſome perſons of credit have obſerved the plants to continue in good ſtrength and health near twenty years. [I ſuppoſe they mean here and there particular plants, and not a whole plantation.] Tull, indeed, tells us that, except lucern be choaked or ſtarved by graſs and weeds, he hardly knew when to ſay it will die a natural death; and probably it may not prove the leſs long lived for being tranſplanted; ſince hand-hoeings, horſe-hoeings, and digging, will give new ſtrength and health to the plants. The ſpreading of the roots will be facilitated by looſening the ſoil, and letting in the good influences of the atmoſphere: their growth alſo will be augmented by giving them that additional nouriſhment of which the weeds defrauded them: and, in the laſt place, all manures will more eaſily reach them; for thus much is a certain fact in huſbandry, that, when the ground is rendered clean, light, and penetrable, the roots love to expand themſelves, in order to procure a greater quantity of nouriſhment.

I fairly acknowledge that I am not enabled, from my own experience, to fix the common duration of lucern, whether tranſplanted or drilled (and that from no difficulty in the thing itſelf, but becauſe a ſufficient number of years has not elapſed ſince making my experiments;) but thus much I can take upon me to ſay, from my own knowledge, that lucern ſown at random, or by what we call promiſcuous ſowing, as the ploughman ſows rye-graſs and clover, (whether with or without ſpring-corn) will not laſt to any tolerable purpoſe above two years, or three at moſt. But, as this plant is of the greateſt uſe and value, where land is dear and ſcarce, as near cities and towns, I ſee no reaſon to doubt, but that the ſame ſpot of ground may be continued as a lucern plantation for half a century at leaſt: for if the rows are three feet four inches wide, (which I look upon to be a *ſine qua non*) then, whenever the old lucern decays, new lines may be planted in the middle of each interval, which has lain fallow, and alſo been manured and pulverized for a conſiderable number of years; and thus progreſſively, *vice verſa*, to a long continuance.

Not being able therefore to give poſitive ſatisfaction concerning the continuance of lucern rightly managed, I ſhall propoſe ſomething that is not merely a query, and which, perhaps, may give the reader an equivalent information. In a few words, it is as follows: when lucern is grown old, and the owner propoſes to break up the plantation, layers might be made from all the principal ſtalks, and removed into freſh ground. Theſe layers, in all probability, may ſucceed extremely well, according to ſome few experiments made abroad in the years 1755 and 1756.

As to the expence and riſque of cultivating ſmall quantities of ground, agreeably to the method here laid down, it is to be hoped that curious gentlemen will not be deterred by ſome few minute difficulties or objections, but give the preſent experiment fair, patient, and repeated trials; for neither the out-goings nor the hazard will be very conſiderable. But at preſent it is no-ways our intention to perſuade farmers (at leaſt ſuch as are in low circumſtances) to quit their little certainty for an advantage which may appear to them quite uncertain.

Let them wait, at leaſt for a few years, in hopes ſome cheaper and more compendious method may be diſcovered for their ſakes; and if, at preſent, they make any experiments, let them be in ſmall.

The firſt point of conſideration, when I undertook to recommend tranſplanted lucern to the public, from my own experiments, was to bear conſtantly in mind whether the profit counterbalanced the expences and labour of culture, and that in a double or even treble proportion; ſince, otherwiſe, I was doing little more than poſtponing utility, for the ſake of introducing a new ſort of huſbandry, which only deſerved to be called ingenious.

We all know that the farmer expends much money, and gains very little from a crop of wheat at the expiration of his twelve months; but if we take ten years together, and compare the profits of lucern on the one hand, and wheat, barley, oats, and clover, on the other, the balance will certainly turn in favour of the lucern-crops, and that in a proportion of three, or two, to one, at leaſt.

The expence of raiſing an acre of lucern in the manner which we recommend, (and ſuppoſing even digging to be made uſe of inſtead of ploughing) amounts, as nearly as I can remember, to the following ſums:

	l.	s.	d.
Fine-digging and picking thirty perches for a nurſery	0	12	0
Seed	0	7	0
Hand-weeding the nurſery twice, and tranſplanting into vacant patches ſuch plants as ſtand too thick	0	13	0
Digging an acre for receiving the roots	2	10	0
Tranſplanting	1	5	0
Hand-weeding and hand-hoeing the rows, with a four-inch hoe that cuts downwards, and then with a larger plantation-hoe which cuts horizontally	1	0	0
Two horſe-hoeings	0	5	0
Total	6	12	0

It is true, the expences of raiſing lucern, in this manner, will vary, when applied to parts of England different from thoſe where the experiment was made, as the price of labour may be dearer, and rents run higher; but then the ground ought to prove better, which will balance the difference.

This plantation of lucern may be cut three times the firſt year after tranſplanting, as ſome repayment for the out-going expences: next year the profit will be more conſiderable.

On the other hand, thoſe who prefer the drill-method of raiſing lucern, as leſs expenſive, may ſeem to ſave about two pounds, or more, upon an acre, at the firſt appearance of things; but then the rows, in caſe the crop ſucceeds (which is a doubtful point) muſt be thinned with good judgment, which will coſt money; and the vacancies in them muſt be filled at laſt with tranſplanted roots: nay, M. de Chateauvieux aſſerts, that drilled lucern will rarely be ſo large and flouriſhing as the tranſplanted; for the effects of horſe-hoeing, and the influence of manures, may prove of leſs ſervice to the roots of the former, at a depth of twelve or thirteen feet, than to the roots of the latter, whoſe fineſt imperceptible fibres will hardly deſcend above a yard perpendicular.

It is hard to ſay at what preciſe time the aſſiſtance of the hoe-plough ſhould be called in: but the owner of the plantation may venture on the attempt, I think, with ſafety, in three days after the ſecond cutting, about the beginning of June; for the roots then will be tolerably well ſettled in the ground, and before that time the flat plantation-hoe may be uſed, chuſing ſuch an one as is about eight inches and a half wide in the cutting part.

As continued hand-hoeings will be chargeable, troubleſome, and almoſt endleſs (being in truth little more than a temporary expedient, and ſlight ſcratching the ſurface of the earth) remember to make a light plough, with which you are to cultivate the ſpaces between the rows; and in this caſe you may either invent a plough according to your own fancy, or copy ſuch as are uſed at home, or in other countries, on the like occaſion.

The ſhare of this plough ſhould be ſharp, about ſixteen inches long, with a coulter proportionable; the plough itſelf no heavier than a ſtrong lad of fifteen years of age can carry: and thus one horſe, after ſome obſtructions of no great conſequence in the firſt attempt, will afterwards draw it with eaſe. Yet ſtill the trouble will be leſſened, if the field be prepared by digging and picking up the roots and ſtones, inſtead of common ploughing, juſt before the ground is to receive the tranſplanted roots: therefore, after a full ſecond conſideration, the former practice is recommended preferably to the latter; and if the lucern ſtands nine or ten years, the difference of the expence will not be perceived.

As the rows will be one yard four inches aſunder, there will be room ſufficient to guide the plough ſafely along the intervals, and yet no room to ſpare: it behoves the ploughman therefore to be extremely careful in the ſlice he cuts next the lines: ſuch a ſtroke muſt be a ſhallow and a dexterous one; nor muſt he approach too nearly. A man, an horſe, and a boy to lead the horſe, will manage an acre in a day, when they know their buſineſs; for it is more a matter of nicety than fatigue, ſince the ground ploughed in an acre will hardly exceed half an acre.

After the firſt time of uſing the horſe-hoe plough (which a man's own diſcretion, upon conſidering the ſtrength of the plants, will beſt determine) it may be laid down for a general rule, that it will be always found moſt convenient to horſe-hoe the intervals (as long as the plantation ſtands) the third day after each cutting; for by that time the new ſhoots will make the plants viſible, nor will any ſide-branches ſtand in the plough's way.

It may be proper alſo to hand-weed the lines once a year; and the larger weeds may be taken up expeditiouſly with the three-pronged ſpade, or the field-ſpade.

We will now conſider the expences of an acre of lucern the ſecond year, which will ſtand as follow:

	l.	s.	d.
Clearing the lucern-plants from weeds in the rows by hand	0	8	0
One hand-hoeing of the intervals	0	8	0
Four horſe-hoe ploughings	0	11	0
Compoſt-dreſſing for manure, or ſoot, or wood, peat aſhes, at an average per year	0	10	0
Diſperſing the manure	0	3	0
Total	2	0	0

Such will be the yearly charges, or in ſome proportion very like them, during the continuance of your lucern, which I fix at a medium of ten years: M. de Chateauvieux ſays it may laſt twenty; and Pliny goes at far as thirty; though the expreſſion may be looked upon to be exaggerated.

In regard to manuring lucern, it may ſuffice to ſuggeſt here in general terms, that if the ground be ſtiff, cold, and of a clayey tendency, then wood-aſhes, ſoot, and lime, are proper dreſſings. If the ground be hot, ſhallow, and braſhy, a compoſt of calcined clay, dung rotted to a fine mould, and pond mud, long expoſed to ſun and froſts, and frequently turned, may have its uſe: and if the ground proves of a middle nature, then malt-duſt will not be amiſs. All theſe manures are eaſily procured, and therefore we have mentioned none that are ſcarce and dear: but as variations of ſoil are infinite, and few people know the true nature of any field (eſpecially if it be of the mixed kind) we recommend the compoſt dung-hill, as the ſureſt and moſt univerſal aſſiſtant upon ſuch occaſions.

Many other manures may be good for lucern, but dung probably is not one of the beſt, except it be very old, and well corrected with proper mixtures of a ſweet, as well as fertilizing nature, ſufficiently warm and cheriſhing, but no ways rank; for dung (eſpecially if it be new) produces

in

in general very luxuriant, troubleſome weeds, inſects in abundance of various kinds, and gives the graſs a foul, cloying, putrefied taſte.

The owner's eye, it is true, may be deceived, and his hopes encouraged by the largeneſs of the crop; but the ſagacious four-footed animals will diſtinguiſh better than we can pretend to diſtinguiſh; and if they could preſent a petition to their maſters, as the white heifers are reported once to have done to the emperor Julian, they would remonſtrate not a little againſt the immoderate uſe of this manure. Nevertheleſs, aſſertions like the preſent ought to be confirmed by ſome proof: an experiment therefore was made upon four acres of graſs-ground, of which one half was dreſſed with ſtable dung, and the other with wood aſhes kept dry. The former moiety appeared the moſt rich and luxuriant of the two, but the cattle always neglected it, till they had bitten the latter down to the bare earth.

Having thus given the reſult of my experience in regard to dung as a manure for lucern, I ſhall ſubjoin only one ſhort caution, which is, that no dung, not even of the beſt kinds, muſt be ſpread on a lucern plantation, till it be two years old at leaſt.

In all grounds inclinable to moiſture, and ſuch particularly as are of a clayey caſt, it is pretty certain, that the preference ought to be given to ſoot-dreſſing, and, after ſoot, to chimney-aſhes (thoſe of green wood eſpecially) provided they are houſed and ſecured from wet; then ſoap-boilers aſhes may take place, coal-aſhes well ſifted, charcoal-aſhes, and malt-duſt; nor might the aſhes of lime be amiſs, nor lime itſelf, when mixed with ſuch fine mould as may be found under a ſhort ſweet turf, in lanes or commons. The compoſt-dunghill alſo, as obſerved before, ſhould be applied to, which, at the end of twelve months, having been thrice turned, will ſpread almoſt as well as aſhes or ſoot: nor will ſuch compoſt want ſtrength when it is rightly managed; for if the dunghill be moiſtened at times with the brine, ſoap-ſuds, diſh-waſhings, and chamber-lie, &c. of the family, then, when it is removed into the fields, the ſharp, pungent, ſtrong ſalts, which fly off, will make the labourers ſneeze, and occaſion a ſmarting in their eyes.

When you manure lucern with ſoot, dry chimney-aſhes, lime, ſoap-boilers aſhes, &c. it is ſufficient to dreſs the rows only, becauſe theſe finer ſorts of manure may be diſperſed in the niceſt exacteſt quantities, if ſown in the Berkſhire manner, with a peat-aſh ſpoon; but if coarſer manures are to be employed in larger quantities, as old dung, marle, compoſt-dreſſings, &c. I would then adviſe the proprietor of the field to manure the intervals and rows promiſcuouſly.

Nothing can be more cheaply and eaſily managed than manuring lucern with ſoot-dreſſings; for the labourer, if he makes uſe of a peat-aſh ſpoon and ſeed-lip, may ſprinkle the rows of an acre in four or five hours, walking down the firſt interval and returning by the ſecond, and ſo progreſſively.

Aſhes may be ſown in the ſame manner.

It may not be amiſs to anſwer a couple of queſtions which have been often propoſed.

The firſt queſtion is, How, and in what manner (by way of reſult from the conſiderable number of experiments made by me) I would adviſe any gentleman to prepare three or four acres of land for receiving lucern? this being an undertaking of ſome moment.

The ſecond queſtion is, How to perform this work in the ſhorteſt, ſafeſt, and moſt œconomical manner? Concerning both which points my ideas are as follow, this only premiſed, that I am here endeavouring to make the expence of the undertaking as cheap as poſſible; otherwiſe, where people pay no regard to a few incidental charges, I would recommend Mr. Boyle's method of preparing a field for receiving tranſplanted lucern, who began his experiments of lucern in the ſame year that I did, but proceeded upon a larger ſcale; for he undertook the culture of ſix acres at once.

His preparation of the field was as follows:

In the year 1757, he gave his field a ſummer fallow, and having thoroughly ploughed and harrowed it (not as farmers underſtand theſe words, but effectually, inſtead of ſuperficially) he ſowed wheat after the ground had been dreſſed with lime. In 1758, his crop of wheat was very great. Immediately after harveſt, he gave the land in queſtion a ſevere diſcipline, uſing every method for pulverizing the earth, and extirpating weeds, that the beſt huſbandmen are acquainted with, either in our kingdoms or abroad; ſo that the field appeared again a perfect fallow. Then ploughing it very narrow and ſharp, he made water thoroughs with the plough, and left it in this condition for the winter 1758.

In ſpring 1759, he made many French drains in the field, as before he had made open ones for the winter; and, by ſtone-picking the land, had nearly ſtones ſufficient to fill them. In March the ſame year (taking advantage of the firſt fine weather) he ſlit the ridges with the plough, and reduced the land to the fineſt tilth he was able, and tranſplanted the lucern from his nurſery in autumn; in the whole proceſs of which he followed Du Hamel exactly.

Nothing in huſbandry could be more ſenſible and maſterly, than this preparation of a large piece of land for receiving lucern.

In the preſent caſe it may ſuffice to ſay, that ſuppoſing the nurſery to be properly prepared, and the ſeeds ſown in the firſt week of April, before the ſeaſon for tranſplanting, according to directions already given; I would recommend a field in good tilth, after barley harveſt, and before oats have been ſown in it. This field ſhould be thoroughly ploughed and harrowed twice, which we will ſuppoſe to be, for example, in the autumn of the preſent year, 1764. After each ploughing and harrowing, there ſhould be a very diligent burn-beating. But if the ſeaſon ſhould prove too wet at the time of a ſecond burn-beating, we make a virtue of neceſſity, and the weeds and trumpery muſt be raked together and carried off.

Then give the field a trench-fallow ploughing for winter, and early in March, 1765 (if the weather any ways permits) having manured your ground as the relative nature of the ſoil requires, and ploughed and harrowed it again to an exquiſite fineneſs, drill in a crop of field-peaſe, as early in the ſpring as is convenient with prudence and ſafety; for this crop muſt be ripe, and removed, by the laſt day of July. Much depends upon this point of foreſight: however the peaſe, by ſtanding thinner than in hand-ſown promiſcuous crops, being at the ſame time banked and hoed with greater eaſe, and enjoying more room, free air, and ſun-ſhine, will, in all probability, gain an advance of ten days at leaſt in their ripening. This will be a great point ſecured; for it is in huſbandry as in war; there are critical moments, which never preſent themſelves a ſecond time in the ſame campaign.

This

This pea-crop being hacked, and moved from the field by the fourth or fifth of Auguſt, call in all the aſſiſtance you have of huſbandry-ſtrength, or can procure, and plough and harrow the field, and burn the pea-roots, weeds, &c. as often as you have time, before the twentieth of Auguſt; and then (your nurſery being ſuppoſed to be in perfect readineſs) tranſplant your roots as before directed, and contrive to cloſe your work by the end of the month."

Mr. Lullin de Chateauvieux has obliged the world with many valuable experiments, on the culture of lucern, which muſt not be omitted here: but it may not be amiſs to give firſt Mr. Miller's directions for cultivating lucern, as it has been often mentioned in the article. They are as follows:

"After having well ploughed and harrowed the land very fine, you ſhould make a drill quite acroſs the ground, almoſt an inch deep, into which the ſeeds ſhould be ſcattered very thin: then cover them over a quarter of an inch thick, or ſomewhat more, with the earth: then proceed to make another drill, about a foot and a half from the former, ſowing the ſeeds therein in the ſame manner as before, and ſo proceed through the whole ſpot of ground, allowing the ſame diſtance between row and row, and ſcatter the ſeeds very thin in the drills. In this manner, an acre of land will require about ſix pounds of ſeed; for when it is ſown thicker, if the ſeeds grow well, the plants will be ſo cloſe as to ſpoil each other in a year or two, the heads of them growing to a conſiderable ſize, as will alſo the roots, provided they have room. I have meaſured the crown of one root, which was in my poſſeſſion, eighteen inches diameter, from which I cut near four hundred ſhoots at one time, which is an extraordinary increaſe, and this upon a poor dry gravelly ſoil, which had not been dunged for many years, but the root was at leaſt ten years old; ſo that if this crop be well cultivated, it will continue many years, and be equally good as when it was firſt ſown: for the roots generally run down very deep in the ground, provided the ſoil be dry; and although they ſhould meet a hard gravel a foot below the ſurface, yet their roots would penetrate it, and make their way downwards, as I have experienced, having taken up ſome of them, which were above a yard in length, and had run two feet into a rock of gravel, ſo hard as not to be looſened without mattocks and crows of iron, and that with much difficulty.

"The reaſon for directing this ſeed to be ſown in rows is, that the plants may have room to grow; and for the better ſtirring the ground between them, to deſtroy the weeds, and encourage the growth of the plants, which may be very eaſily effected with a Dutch hoe, juſt after the cutting the crop each time, which will cauſe the plants to ſhoot again in a very little time, and be much ſtronger in ſuch places where the ground cannot be ſtirred: but when the plants firſt come up, the ground between ſhould be hoed with a common hoe; and if, in doing of this, you cut up the plants where they are too thick, it will cauſe the remaining to be much ſtronger. This hoeing ſhould be repeated two or three times while the plants are young, according as the weeds are produced, obſerving always to do it in dry weather, that the weeds may the better be deſtroyed; for if it be done in moiſt weather, they will root and grow again.

"With this management, the plants will grow to the height of two feet or more, by the beginning of Auguſt, when the flowers will begin to appear, at which time the lucern ſhould be cut, obſerving to do it in a dry ſeaſon, if it is to be made hay, and keep it often turned, that it may ſoon dry, and be carried off the ground; for if it lie long upon the roots, it will prevent their ſhooting again. After the crop is taken off, you ſhould ſtir the ground between the rows with a hoe, to kill the weeds, and looſen the ſurface, which will cauſe the plants to ſhoot out again in a ſhort time; ſo that by the beginning of September there will be ſhoots four or five inches high, when you may turn in ſheep upon it to feed it down: nor ſhould the ſhoots be ſuffered to remain upon the plants, which would decay when the froſty weather comes on, and fall down upon the crown of the roots, and prevent their ſhooting early in the ſucceeding ſpring.

"The beſt way therefore is to feed it until November, when it will have done ſhooting for that ſeaſon: but it ſhould not be fed by large cattle the firſt year, becauſe the roots being young, would be in danger of being deſtroyed, either by their trampling upon them, or their pulling them out of the ground: but ſheep will be of ſervice to the roots by dunging the ground, provided they do not eat it too cloſe, ſo as to endanger the crown of the roots.

"In the beginning of February, the ground between the rows ſhould be again ſtirred with the hoe, to encourage them to ſhoot again: but in doing of this you ſhould be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to puſh. With this management, if the ſoil be warm, by the middle of March the ſhoots will be five or ſix inches high, when, if you are in want of fodder, you may feed it down till a week in April; after which it ſhould be ſuffered to grow for a crop, which will be fit to cut the beginning of June, when you ſhould obſerve to get it off the ground as ſoon as poſſible, and ſtir the ground again with the Dutch hoe, which will forward the plants ſhooting again, ſo that by the middle or latter end of July, there will be another crop fit to cut, which muſt be managed as before; after which it ſhould be fed down again in autumn: and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you ſhould turn in larger cattle; but you muſt always obſerve not to ſuffer them to remain after the roots have done ſhooting, leſt they ſhould eat down the crown of the roots below the bud, which would conſiderably damage, if not deſtroy them.

"In this manner you may continue conſtantly to have two crops to cut, and two feedings upon this plant, and in good ſeaſons there may be three crops cut, and two feedings, which will be a great improvement, eſpecially as this plant will grow upon dry barren ſoils, where graſs will come to little, and be of great uſe in dry ſummers, when graſs is often burnt up: and as it is an early plant in the ſpring, ſo it will be of great ſervice when fodder falls ſhort at that ſeaſon, when it will be fit to feed at leaſt a month before graſs or clover; for I have had this plant eight inches high by the tenth of March, old ſtyle, at which time the graſs in the ſame place has ſcarcely been one inch high.

"That cold will not injure this plant, I am fully ſatisfied; for in the very cold winter, anno 1728-9, I had ſome roots of this plant which were dug up in October, and laid upon the ground in the open air till the beginning of March, when I planted them again, and they ſhot out very

very vigorouſly ſoon after: nay, even while they lay upon the ground, they ſtruck out fibres from under the ſide of the roots, and had begun to ſhoot green from the crown of the roots. But that wet will deſtroy the roots, I am fully convinced; for I ſowed a little of the ſeed upon a moiſt ſpot of ground for a trial, which came up very well, and flouriſhed exceedingly during the ſummer ſeaſon, but in winter, when the great rains fell, the roots began to rot at bottom, and before the ſpring moſt of them were deſtroyed.

"The beſt places to procure the ſeed from, are Switzerland and the northern parts of France, which ſucceeds better with us than that which comes from a more ſouthern climate: but this ſeed may be ſaved in England in great plenty; in order to which, a ſmall quantity of the plants ſhould be ſuffered to grow uncut till the ſeeds are ripe, when it muſt be cut, and laid to dry in an open barn, where the air may freely paſs through: but the ſeed muſt be defended from the wet; for if it be expoſed thereto, it will ſhoot while it remains in the pod, whereby it will be ſpoiled. When it is quite dry, it muſt be threſhed out, and cleanſed from the huſk, and preſerved in a dry place till the ſeaſon for ſowing it: and this ſeed ſaved in England is much preferable to any brought from abroad, as I have ſeveral times experienced; the plants produced from it having been much ſtronger than thoſe produced from the French, Helvetian, and Turkey ſeeds, which were ſown at the ſame time, and on the ſame ſoil and ſituation.

"I am inclinable to think that the reaſon of this plant's not ſucceeding, when it has been ſown in England, has either been occaſioned by the ſowing it with corn, with which it will by no means thrive (for though the plant be very hardy when grown pretty large, yet at its firſt coming up, if it be incommoded by any other plant or weeds, it ſeldom does well; therefore it ſhould always be ſown by itſelf, and carefully cleared from weeds until it has ſtrength, after which it is not eaſily deſtroyed;) or, perhaps, people have ſown it at a wrong ſeaſon, or in wet weather, whereby the ſeeds have rotted, and never come up, which hath diſcouraged their attempting it again: but however the ſucceſs has been, I dare aver, that if the method of ſowing or managing this plant, which is here laid down, be duly followed, it will be found to thrive as well as any other ſort of fodder now cultivated in England, and will continue much longer: for if the ground be duly ſtirred after the cutting of each crop, and the firſt crop fed, as hath been directed, the plants will continue in vigour twenty years, or more, without renewing, provided they are not permitted to ſeed, which would weaken the roots more than four times cutting would do.

"The hay of this plant ſhould be kept in cloſe barns, it being too tender to be kept in ricks open to the air as other hay: but it will remain good, if well dried before it be carried in, three years. The people abroad reckon an acre of this fodder ſufficient to keep three horſes all the year round: and I have been aſſured by perſons of undoubted credit, who have cultivated this plant in England, that three acres of it have fed ten cart-horſes from the end of April to the beginning of October, without any other food, though they have been conſtantly worked. Indeed the beſt uſe that can be made of this graſs is, to cut it and give it green to the cattle. Where this hath been daily practiſed, I have obſerved that by the time the field has been cut over, that part which was firſt cut, hath been ready to cut again; ſo that there has been a conſtant ſupply in the ſame field, from the middle of April to the end of October, when the ſeaſon has continued long mild; and when the ſummers have proved ſhowery, I have known ſix crops cut in one ſeaſon: but in the dry ſeaſons there will be always three. When the plant begins to flower, it ſhould then be cut: for if it ſtands longer, the ſtalks will grow hard, and the under leaves will decay, then the cattle will not ſo readily eat it. Where there is a quantity of this cultivated, ſome of it ſhould be cut before the flowers appear, otherwiſe there will be too much to cut within a proper time.

"When this is made into hay, it will require a great deal of making: for as the ſtalks are very ſucculent, it muſt be often turned, and expoſed a fortnight before it be fit to houſe; for this requires a longer time to make than ſainfoin: therefore, when it is cut, it ſhould be carried to make upon ſome graſs-ground; becauſe the earth in the intervals of the rows will waſh up, and mix with the hay in every ſhower of rain; and, by carrying it off as ſoon as it is cut, the plants will ſhoot out again ſoon: but it is not ſo profitable for hay, as to cut green for all ſorts of cattle, but eſpecially horſes, which are extremely fond of it; and to them it will anſwer the purpoſe of both hay and corn, and they may be worked at the ſame time juſt as much as when they are fed with corn, or dry food." *Miller's Gard. Dict.*

EXPERIMENTS *on Lucern cultivated according to the New Huſbandry, by* M. de Chateauvieux.

"It is truly with regret, ſays M. de Chateauvieux, that I am forced to treat a ſubject of this importance, in ſo ſummary a way as the limits of this letter require. However, I hope that even this general account of my experiments may be a guide to thoſe who would cultivate this plant. Many perſons who live at a conſiderable diſtance from this place [Geneva] have already followed my example, and are extremely well ſatisfied with their ſucceſs.

"Though I agree with M. Duhamel and the other partiſans of the New Huſbandry, that lucern and ſainfoin thrive beſt when cultivated in beds; yet my practice differs, in many reſpects, from theirs. This difference conſiſts in,

1. *The Principle which I apply particularly to the Culture of Lucern.*

"Lucern grows naturally with one large perpendicular, or tap-root, which penetrates very deep into the earth, and has few, if any, lateral roots. From ſimilar experiments on other tap-rooted plants, I was induced to think, that this too, by tranſplanting it, and at the ſame time cutting off part of its tap-root, might be made to ſhoot out ſeveral horizontal roots, which, reaching into the looſe mould of the alleys, and extending themſelves there, would collect a greater quantity of nouriſhment for the plant, and conſequently enable it to produce more abundant crops.

"The event has proved, that when we reaſon on ſound principles, we ſeldom err. My tranſplanted lucern puſhed out numbers of large lateral roots, and theſe branched out again into others, which may be multiplied without end by frequent culture of the alleys: for the horſe-hoe has the ſame effect on theſe horizontal roots as cutting has upon the tap-root.

2. *The*

2. *The Method of tranſplanting the Lucern.*

" I made ſeveral beds, ſome about three feet wide, (including the alleys) into which I tranſplanted a ſingle row of lucern; others about three feet nine inches, into which I tranſplanted two rows; and others about four feet three inches wide, in which I put three rows. The deſign of this variation was, to ſee by which of theſe three methods the ſame extent of ground will produce the greateſt quantity of lucern. I believe it will require five or ſix years to determine exactly which of them will be beſt; becauſe, as the plants increaſe every year in bulk, their produce alters, and may perhaps not keep in proportion to their firſt years, though probably the difference will not be great. But without waiting ſo long, I can already ſee, that the crop will be greateſt by planting only one row on each bed.

" The plants in the ſingle rows were ſix inches aſunder, nor ſhould they ever be nearer; and thoſe in the double and triple rows, were eight or nine inches diſtant from each other. I muſt obſerve, that I likewiſe ſowed lucern with the drill, in beds, in which it has remained without tranſplanting. It is very fine; but not near ſo ſtrong and flouriſhing as that which I tranſplanted. When lucern is ſown where it is to remain, it neceſſarily requires being thinned, and that operation takes up more time than tranſplanting it would do."

Rules to be obſerved in tranſplanting Lucern into Beds.

" 1. The middle of the beds muſt be raiſed and arched as high as poſſible; and as the lucern is to remain ſeveral years on the ſame ground, no pains ſhould be ſpared to prepare the earth as well as can be.

" 2. Lucern ſhould be ſown in the ſpring, and in a rich mould, that the plants may be ſtrong enough to tranſplant in September.

" 3. Plants two or three years old may be tranſplanted as well as younger ones.

" 4. They ſhould be tranſplanted in September, that they may have time to take freſh root before the winter comes on.

" 5. If they cannot conveniently be tranſplanted in September, it may be done in October, provided the weather be not froſty.

" 6. The mould into which they are tranſplanted ſhould be moiſt; and if the weather be ſomewhat rainy, it is ſo much the better. In this caſe, I have never found it neceſſary to water the plants.

" 7. If lucern is tranſplanted in November or December, there is danger of the froſts forcing many of the plants out of the ground.

" 8. If too warm and dry a ſeaſon prevents tranſplanting in September or October, it is beſt to ſtay till the winter is paſt. The plants will then be ſure of taking root, and very few of them will fail.

" 9. If they can be tranſplanted in autumn, they will yield pretty good crops the next year: but if they are not tranſplanted till ſpring, the next year's crop will be but indifferent.

" 10. The plants muſt be taken up out of the nurſery, with great care and patience, that their roots may not be damaged.

" 11. The roots ſhould be left about ſix or ſeven inches long, and the green tops ſhould be cut off within about two inches of the crown of the root.

" 12. The plants will take root the ſooner, if they are put into water as ſoon as they are taken up, and kept in it till they are planted.

" 13. They are planted in holes made with a planting ſtick, in the ſame manner as cabbages or lettuces are planted in a garden.

" 14. The beſt way of planting lucern is, to cut a ſtrait channel two or three inches deep, and ſet the plants in the bottom of it, covering them up to the neck.

" 15. Great care ſhould be taken not to ſuffer any weeds to grow among the lucern; at leaſt for the two or three firſt years. To this end, the rows ſhould be weeded by hand, as well as the edge of the alleys near the plants, where the horſe-hoe cannot go.

" 16. The alleys may be ſtirred, either with the ſingle cultivator, or the cultivator with two mould-boards; which, at the ſame time that it deſtroys the weeds, keeps the mould looſe.

" 17. The firſt ſtirring may be given with the ſingle cultivator, with which a furrow may be cut on each ſide of the main furrow in the middle of the alleys, by which means the earth will be turned over on both ſides of it.

" 18. The ſecond ſtirring may be given by the cultivator with two mould-boards, by drawing it along the middle of the alleys. This will turn the earth towards the rows. By theſe alternate ſtirrings, the alley will be conſtantly kept in a looſe ſtate.

" 19. This culture is ſo eaſily performed, and in ſo ſhort a time, that it may be repeated frequently. In this I differ from M. Duhamel, who orders it but ſeldom. My opinion is, that the alley ſhould be ſtirred once a month, during the whole time that the lucern is in a growing ſtate.

" 20. If the alleys be kept from weeds, leſs ſtirring them may do: but the mould ſhould never be ſuffered to grow too hard.

" 21. As ſoon as ſome of the plants begin to bloſſom, the lucern ſhould be cut. It will then make excellent fodder, ſuperior to every other kind.

" 22. The lucern hay ſhould be dried as quick as poſſible, and frequently turned. The leſs it is expoſed to the heat of the ſun, the better fodder it makes.

" 23. Lucern muſt not be houſed till it is dry: but at the ſame time care muſt be taken that it be not too dry: for then many of the leaves will fall off, as they dry ſooner than the ſtalks.

" 24. Cattle muſt not have too much lucern given them at a time, till they are accuſtomed to it.

" 25. No cattle ſhould ever be ſuffered to feed on the beds of lucern. If the earth is very dry, towards the latter end of autumn, ſheep will do it the leaſt hurt. If the plants are then tall enough to be mowed, the beſt way is to cut them, and give them green to the cattle.

" Theſe rules contain all that is eſſentially neceſſary for making and keeping in good order this kind of artificial paſture. I can ſafely ſay, that whoever tries them, will be abundantly rewarded for his trouble and expence. Sainfoin may be cultivated in the ſame manner."

Account

Account of the Produce of Lucern planted in Beds, and cultivated according to the Principles of the New Huſbandry: with ſome important Reflections on the Advantages which may be obtained therefrom: by M. de Chateauvieux.

"No judgment ſhould be formed of what lucern may produce, by the crops of the firſt or ſecond year: it is then too young to be able to yield much. If we were to calculate even by its third year's produce, we ſhould ſtill conſider, that as the plants increaſe every year in bulk and vigour (and where they will ſtop I am not yet able to determine) the produce will be proportioned to that increaſe, and conſequently the crop of each ſucceeding year will be greater than that of the former.

"The crops I am going to ſpeak of, are thoſe of the ſecond and third year: but my calculations will be made on that of the third year. It is proper to remember, that the years 1753 and 1754 were uncommonly dry, inſomuch that, ſometimes, not a drop of rain, nor ſcarce any dew, fell between the cutting of one crop and that of another. The ſeaſons were ſo unfavourable to the production of graſs, that hay roſe to an exceſſive price.

I ſhall firſt ſay what was the ſtate of the plants of lucern in their third year, and afterwards how much hay they yielded.

State of the Plants in their third Year.

"As the part of the plant which I now conſider is that which is buried in the earth, I uncovered numbers of them, that I might be able to judge of their general ſtate. I was greatly ſtruck with the effect which tranſplanting had had upon them. Inſtead of one perpendicular root, which they uſually have, all theſe plants had three, four, five, and ſometimes more, almoſt equally big roots. They were, in general, three quarters of an inch in diameter, and proceeded from the original root, which was now at leaſt an inch in diameter, and in many of the plants an inch and a half. After the moſt careful ſearch that I could poſſibly make, I could not find one plant of lucern ſown in the common way, though it had ſtood twelve, twenty, or more, years, whoſe tap-root had grown to the bigneſs of an inch diameter: few of them were above half, or at moſt three quarters of an inch thick. This difference is very great.

"I likewiſe found, that the roots of the tranſplanted lucern had produced another kind of roots, of which I ſaw none about thoſe of the old lucern. Theſe were a great number of fibrous roots, ſome of which were already one twelfth of an inch in diameter, and looked as if they would alſo become principal roots.

"The ſtalks ſeem to riſe out of the earth; and from the firſt time of cutting them, a kind of head forms juſt above ground, which extends itſelf every year. The firſt year, this head was two or three inches wide: the ſecond year it was generally about ſix inches over, and this third year, almoſt half the plants have a crown ten or twelve inches in diameter: and as many of them have grown ſo as to touch one another, their crowns are become of an oval form, having extended themſelves on the ſides where they met with no reſiſtance.

CROPS.

"I have a field of lucern in beds, divided into two parts. This is the third crop of lucern off one of them. The beds are 250 feet long. In 1753, I cut this lucern ſix times, viz. in May, June, July, Auguſt, September, and the beginning of November. This laſt cutting was not near ſo plentiful as the others, and I dried it within doors.

"Theſe cuttings off one bed, on which there was but one row of lucern, yielded 140 pounds of well dried hay.

"In 1754, the lucern was late before it began to ſhoot, and the earth was drier than the year before. I had but five crops: the firſt was cut on the 27th of May; the ſecond on the firſt of July; the third on the 27th of July; the fourth on the 26th of Auguſt; and the fifth on the 23d of October. Theſe five cuttings yielded in all 225 pounds of well dried hay off each bed.

"A field 250 feet long, which was the length of my beds, and 210 feet wide, contains an arpent of our meaſure. This arpent, divided into ſixty-eight beds, each three feet wide, producing after the rate of 225 pounds of hay off each bed, would yield in all 15300 pounds; which is infinitely more than is ever obtained in the common way.

"The beds with three rows yielded much leſs. The third year, their crops amounted to no more than 169 pounds off each bed, which is a fourth leſs than the others: and as theſe beds are wider, inſtead of having ſixty-eight, as in the former diſpoſition of the arpent, there will be only forty-ſeven, each four feet three inches wide, the total produce of which will be but 7943 pounds: conſequently this arpent will yield little more than half as much as an arpent laid out in beds three feet wide, planted with only ſingle rows.

Remarks by M. de Chateauvieux.

"The plants of lucern had the fate of all kinds of plantations: that is to ſay, ſome of them were more vigorous than others. The greateſt number of the plants produced each of them a pound of dry hay, and ſome of them yielded two pounds. I look upon theſe laſt as ſuch extraordinary productions, that I do not expect many of them to yield the like quantity again. I think one may be very well ſatisfied, if the plants one with another, yield a pound of hay a piece every year. This is nearly the reſult of my experiment on beds which had but one row; and the produce of theſe would have been ſtill greater, if many of my plants had not failed: in the room of which I ſet young ones, which could not acquire ſufficient ſtrength to yield full crops.

"In theſe experiments, I have employed no dung: neither have I for any of my corn fields. I have reſerved it for improving my paſtures and meadows; and intend next to apply it to my lucern, which, I doubt not, but will be much the finer for it. The only thing now remaining is, to know by experience which will be the beſt way of uſing it. I have ſome thoughts on that head, which may render it much more profitable.

Lucern deſerves to be cultivated with care: not only on account of the great quantity of fodder which it yields, but likewiſe becauſe the quality of its hay is ſuperior to any other. The New Huſbandry will render it ſtill more perfect. Plants cultivated this way enjoy the benefit of a free circulation of the air, and that circulation keeps them ſweet and ſound, and free from all muſtineſs towards their roots: for, being open to the rays of the ſun, that great ſource of kindly vegetation, they attain great perfection in all their parts, both as to their ſubſtance, and their flavour. Cattle eat this food greedily, and are better nouriſhed with it, than with any other: but as every exceſs

is had, too great a quantity ſhould not be given them at once, eſpecially at firſt, leſt it ſhould ſwell them. The beſt way is to bring them to it by degrees.

"I have experienced theſe qualities in this hay, by comparing it with every other ſort. The excellence of this, juſtifies the principles on which the New-Huſbandry is founded. I have offered to my horſes bundles of every kind of hay, and at the ſame time a bundle of this hay of lucern. They have not heſitated a moment to prefer the latter. Nothing but its ſuperior qualities could determine them in this choice, which never varied, and has always been in favour of the lucern cultivated in this manner.

"It would be laviſhing this excellent fodder, to feed horſes entirely with it. It need only be given them by turns with common hay: which will be a great ſaving: for this lucern will ſupply the place of oats. I am certain that my horſes fed partly with this hay, and without oats, will be in better plight, ſtronger, and more vigorous, than thoſe which are fed with meadow hay and corn in the uſual way. It is now ſome time ſince I have fed my coach-horſes with it, and have retrenched their oats. Inſtead of this laſt food, and at the hours they uſed to have it, I give them lucern chopt, as the Spaniards do ſtraw to their horſes. Mine are fond of it, and ſhew the ſame impatience to find it in their manger, as if it was oats; and ſince their being put under this diet, they are in better condition than before, and ſo mettleſome, that the coachman has enough to do to keep them in.

"When I ſaid that retrenching the oats would be a conſiderable ſaving, I did not ſo much mean the ſaving of the expence of that corn, as the better improving of many vaſt tracts of land which are ſown with oats, and might with proper management, produce much more uſeful and more profitable ſorts of grain, notwithſtanding the too general prejudice, that ſome lands are not capable of bearing any better. For my part, I am thoroughly ſatisfied, that whatever ground can bear a crop of oats, can likewiſe, under the New Huſbandry, bear any other grain."

Continuation of M. de Chateauvieux's *Account of his Experiments on Lucern, in the Years* 1755, *and* 1756.

"The great drought of the year 1755, was accompanied with great heat; and the year 1756 was very rainy, and moderately warm, there being but very few hot days in it.

"My lucern was expoſed to a moſt ſevere winter in 1755, when the froſt was exceſſive hard, and laſted very long. M. de Reaumur's thermometer was ſome days, at different times, eight, nine, ten, twelve, and thirteen degrees below the freezing point; and on the third of February, a thermometer, in the open air, ſtood at ſixteen degrees below freezing. Theſe ſevere froſts made me uneaſy for my lucern, which, however, bore them, without receiving any damage.

"The rains in 1756 did no hurt to theſe plants, but they prevented my cutting them at proper times. I had but four crops of lucern this year, being obliged to wait for an appearance of fine weather to dry it in, before I could venture to cut it down. Theſe rains likewiſe hindered my giving the proper hoeings to the alleys, which were full of weeds during the ſummer and autumn. I choſe rather to leave them in that condition, than attempt to hoe them while the ground was over wet, not doubting but the ſpring hoeings would eaſily deſtroy them.

"In 1755, I cut my lucern five times: the firſt was, on the third of May, before any flowers appeared: the ſecond on the twelfth of June: the third, on the fifteenth of July: the fourth on the twenty-firſt of Auguſt: and the fifth, on the ſeventh of October. I was obliged to finiſh the drying of this laſt cutting, in barns and under cover.

"In 1756, which was the fifth year of theſe plants, I cut them but four times: the firſt, on the third of June: the ſecond, on the firſt of July: the third, on the fourth of Auguſt: and the fourth on the twenty-ſeventh of September.

A bed 250 feet long, with only one row of lucern,

Yielded	In 1754	225	pounds of dry hay.
	1755	197	
	1756	281	

In three years, 703 pounds.

A bed of the ſame length, with three rows of lucern,

Yielded	In 1754	169	pounds of dry hay.
	1755	180	
	1756	226	

In three years, 575 pounds.

Obſervations by M de Chateauvieux.

"We ſee, by the above account of three years, that a piece of ground laid out in narrow beds, planted with only one row of lucern, yielded a greater produce than the ſame extent made into wider beds, and planted with three rows.

"I ſhall not, however, pretend to determine from this one experiment, that it is beſt to lay down large fields in this manner. I think it will be right to try firſt, whether the ſucceſs will be the ſame on different ſoils, and likewiſe on lands whoſe expoſition may be more or leſs advantageous. If after repeated trials, the beds which have but one row of plants, yield the greateſt quantity of hay, that method certainly is to be preferred. To clear up this point ſtill more to my ſatisfaction, I continue to plant lucern in beds, ſome with one and others with three rows.

"The difference between the crop of 1756, and thoſe of the two preceding years, would induce me to think that rainy ſeaſons are beſt for the production of hay: but ſtill, the greater quantity which the year 1756 produced, muſt not be imputed to the rain only: we ſhould likewiſe conſider that the plants had throve greatly ſince 1754; that their ſtems were grown much larger, and their roots much ſtronger and more numerous, and that they were conſequently able to yield much greater crops than before. They have abundantly anſwered my expectation, both as to quantity and quality.

"With reſpect to the quantity, it is much greater than that of any common fodder: I mean, of any that the ſame extent of ground would have produced, if cultivated in the common way, though it would then have been covered with an immenſe quantity of plants. This is a fact, which numbers of experiments prove, and which we ſhall ceaſe to wonder at when we conſider the great effects of the frequent ſtirring of the alleys. To this it is that I owe the repetition of my crops, and their being all of nearly equal goodneſs. I do not exaggerate when I

ſay,

ſay, that every ſummer month, which is the time I generally allow between each cutting, will produce ſhoots two feet long, and ſometimes more: and ſuppoſing that I cut them but five times a year, each plant will have produced after the rate of nine or ten feet length of ſhoots, and that in the ſame time that moſt meadows will not produce graſs above two feet long.

"As to the quality of this hay, I continue to prefer it to all other fodder. My experience has confirmed what I ſaid of it in 1754; and I ſhall only add, that I have ſince found, that it is as good at the end of four years, as when it is firſt cut. If there was any difference, horſes would ſoon be ſenſible of it: but they eat of either without diſtinction.

"I feed my horſes with it, chiefly in the ſummer, at which time they do moſt work, and am more and more ſenſible of the advantages of it. Five or ſix pounds of lucern a day, are ſufficient for a middle ſized horſe: but the quantity may be increaſed or diminiſhed, according as the horſe is nouriſhed by it; for in that there is great difference." *Culture des Terres, tom.* IV. *c.* iii. *art.* 15.

The following account of the cultivation of lucern, was communicated to the public by a very ingenious huſbandman, and merits the attention of the reader.

Having read and heard a great deal of lucern, I determined to have ſome of it myſelf; and Mr. Miller's method ſeeming to me by far the moſt rational, I reſolved to follow it: accordingly, the ſeventeenth of July, 1763, I ordered a field of three acres and a half, then under rye-graſs and clover, to be ploughed deep, and ſown with turnips. The crop was middling: I ſold them to a cow-farmer for nine guineas: he drew and carted them home. If I had had ſheep, I would have fed them on the field.

By the twenty-ſeventh of March, 1764, the field had been twice ploughed, the firſt time ten, and the laſt time near twelve inches deep, with the Rotheran-plough and four horſes a-breaſt: the ſoil is light and ſtoney, with a rock of gravel about ten or twelve inches deep, and had never before been ploughed above ſix or ſeven inches deep; however, I knew it was right to go as deep as I could for a tap-rooted plant, as the lucern is.

I was greatly pleaſed with reading M. Lullin de Chateauvieux's account of his method of tranſplanting lucern, and determined to follow it, from a full conviction that it muſt be ſuperior to every other method.

Accordingly I ordered the field to be ſown with Poland oats, and laid out about twenty-eight rods in beds four feet wide, alleys one foot and a half, which were ſown with lucern in broad-caſt by my gardener, in the ſame manner as you ſow cabbages or ſavoys in ſeed-beds: one bed, however, out of curioſity, I ordered him to ſow in the following manner.

Run a garden-line through the middle of the bed from one end to the other; draw a ſmall drill along the line, about half an inch deep; then move the line ſix inches, and make another drill, and ſo on: by this means you will have nine drills on a bed four feet wide. When this is done, fill a quart or pint bottle near full with your lucern-ſeed, cork the bottle, bore a hole in the cork, and inſert a quill cut at each end: this will be found a great aſſiſtance in ſowing the ſeed thin and regularly in the drills: and I muſt obſerve, that the bed which I ſowed in this manner, afforded me much the greateſt quantity of plants, and by far the fineſt. Another advantage attending it is, that it is kept clean with much more eaſe, and far leſs expence; for a gardener, with the ſmall three-inch hand-hoe, will clean a great deal of ground in a ſmall ſpace of time. When the bed is ſown, the ſeed muſt be covered with care: rather chuſe the backſide of a ſmall rake than the teeth.

By the middle of Auguſt, my plants looked very well, and were moſtly in bloom, when I ordered them to be mown, and given to my horſes and cows, who ſeemed as if they had a high treat.

The oats being got in, I ordered the field to be deep ploughed again, and then waited for a ſeaſon of rain to begin my planting, which, by my journal, did not come till the fifteenth and ſixteenth of September; and the field being firſt well harrowed, we went to work the ſeventeenth, and continued planting till the twenty-ninth; nor can I now ſee any difference between thoſe planted the ſeventeenth or twenty-ninth. Though I quite agree with the author of the Eſſays, that it is beſt to plant ſooner than I did if poſſible; yet I muſt obſerve, that what may do for gardens, or ſmall pieces of ground, will not do for fields. From the laſt week of Auguſt to the middle of September, ſeems to me a very proper time. But "filling each hole with water, making drills, half filling them with ſea-ſand or wood aſhes, and watering each plant," as the author of the Eſſays mentions, is an endleſs and very expenſive work.

For my part, I kept my eye on M. Chateauvieux's directions, as laid down above, with regard to that part that relates to planting; but another ingenious gentleman, having cautioned the public againſt planting on ridges, I muſt needs ſay, I was fearful of the rain and froſt myſelf, if planted in that manner, eſpecially on light land; and therefore I ordered my field to be ploughed as level as poſſible, and made my man, after the field was ploughed, go three bouts on each ſide the furrows, ſo that, when harrowed acroſs, you could hardly tell where they were. The field being brought to this order, as I ſaid before, we began to plant the 17th of September: two men with ſpades dug up the plants, and two women cut them: ſome care is certainly required in taking them up, but I did not find it great; it was done by common labourers. The women were ordered to cut the plants to about ſix or ſeven inches long in the root, and the tops to about two inches, as M. Chateauvieux directs. They did it very handily: their method was to take them up one by one, (ſo that they could throw by the faulty ones) and when they had about a dozen in their hands, they cut them at top and bottom with one ſtroke of the knife at each end. Each had a waſhing-tub by her ſide, filled to about ſix inches with water: as they cut the plants, they ſet them in the tubs; and as they filled one tub, another was brought them.

The method of planting is the ſame as for cabbages: men who are uſed to work in gardens will do it very handily with a dibble or planting ſtick; but that mine might ſtand with all poſſible exactneſs, each man had a garden-line and reel: and as I think I ſhall be very able to keep them clean with M. Lullin's ſingle cultivator, the rows are only twenty inches apart, and ſix inches in the lines.

If I find a difficulty in keeping them clean in this method, then by drawing every other row, which may be done with great eaſe, my plants will ſtand at the diſtance directed by M. Chateauvieux, of three feet four inches.

I was very impatient to ſee the effect tranſplanting would have, and therefore, as ſoon as my plants in the

ſeed-bed were about ſix inches high, I drew ſeveral, cut and tranſplanted them, and in the autumn I took up theſe plants, and found they had all formed new-tap roots round the bottom of the piece (if I may ſo call it) planted, and inſtead of one, they had from five to thirteen new roots: this, you may ſuppoſe, gave me great pleaſure, and convinced me, that the illuſtrious Swiſs was quite right.

The author of the Eſſays on Huſbandry, I find, cut his plants with ſciſſars: this muſt be very tedious work; and, with ſubmiſſion, I think he is quite wrong in cutting his plants to the length of nine or ten inches. Six or ſeven inches ſeem to me a much properer length; for the ground being dug or ploughed about twelve inches, the new roots will have five or ſix inches of well-looſened mould to ſtrike into, which muſt be a great advantage to the plants; and if gravel, or a ſtrong clay, is near the ſurface, I am convinced mine, or rather M. Lullin's, is the beſt method.

Yet this gentleman ſays, he cut his tap-roots too ſhort, and knew not how to manage a root that was very ſmall: in regard to the laſt, I muſt obſerve, that, if they were very ſmall, I ordered them to be thrown away. So much has been ſaid on the neceſſity of keeping lucern in broad-caſt, drills, or tranſplanted, free from weeds, that I will ſay nothing on that ſubject.

At the ſame time that this gentleman ſo warmly recommends M. Chateauvieux's method of cultivating lucern by tranſplanting, he has, I fear, thrown a ſtumbling-block in the way of moſt gentlemen, and, I think, every farmer; I mean his calculation of the expence: this, therefore, I muſt endeavour to remove.

When I began to cultivate lucern in this manner, the only defect I could find in M. Chateauvieux's account was, that he had not told the public how much ground they were to ſet apart for a nurſery: this deficiency, however, I can ſupply to thoſe who come after me, for ſixteen rod will be about the quantity for an acre; and then, I think, the expence of tranſplanting will ſtand as follows:

	l.	s.	d.
Digging, ſpit-deep, ſixteen rods, at three-pence per rod	0	4	0
Seed, three pounds, at one ſhilling per pound	0	3	0
Weeding the nurſery twice with the three-inch hand-hoe. (By ſowing in this manner, tranſplanting will not be wanted; nor do I think it proper, as they are to be tranſplanted again)	0	3	0
Ploughing	0	10	0
Tranſplanting	1	5	0
Hand-hoeing the plantation once, the middle or latter end of October, in dry weather, which men uſed to hoeing turnips will do for three or four, but ſay	0	5	0
	2	10	0

This, I am perſuaded, is the full expence of making the plantation; yet the author of the Eſſays has ſtrangely worked it up to ſix pounds twelve ſhillings per acre: however, I readily ſubmit this account to the inſpection of every farmer and every gentleman in this kingdom, converſant in matters of this kind.

If the ſpring-ploughing for barley or oats has been nine or ten inches deep, then a ploughing in autumn of twelve inches will be ſufficient, and cannot be charged at more than ten ſhillings. The trenching for the ſeed-beds may be done at leiſure time; ſo may the weeding of the nurſery, and the hand-hoeing of the plantation: then the real expence to the farmer will only be the ſeed and tranſplanting, or one pound eight ſhillings per acre.

As to what this gentleman calls the yearly charges, I can by no means agree to them: for the plantation having been weeded in October, will lie very ſafe and well till the latter end of February or beginning of March: then in dry weather, it may be hand-hoed again, the expence of which has before been charged at five ſhillings per acre; to which add four horſe-hoeings after each cutting, at eleven ſhillings, which makes ſixteen ſhillings per acre the annual charge.

I cannot recollect any thing further that is neceſſary to be ſaid on the ſubject of tranſplanted lucern; but as I would have every one, who writes to you on ſubjects of this ſort, tell the truth, the whole truth, and nothing but the truth; ſo I think it but juſt to ſay a word or two on lucern ſown in broad-caſt, or Mr. Rocque's manner. I live within a few miles of Mr. Rocque; and muſt add, that I have paid great attention to the culture and growth of lucern and burnet for ſome years paſt; ſo that I think I am pretty well accquainted with them.

The author of the Eſſays ſays, "If lucern is ſown broad-caſt with corn, no care can keep it clean: it may laſt two years, only one crop being tolerable, and then muſt periſh in the common courſe of nature." And ſeveral of your correſpondents are alſo of opinion it will never ſucceed in this method; but I know it will; for I have ſeen it cut three and four times. To cut it four times, the ſummer muſt be very favourable, and the laſt cutting will be late. Here I muſt remark, that lucern is not only excellent as a green fodder, but as an early one, eſpecially if ſown in drills, or tranſplanted; for that ſown in broad-caſt will not be fit for cutting ſo ſoon as the former, by a fortnight or more; however, the farmer may depend on three good crops in this manner of ſowing.

In the ſpring 1760, Mr. Rocque ſowed about five acres with lucern and barley: the land is light and hot, but being in good heart, the barley was rank, which obliged him to mow it green, and ſell it to a farmer for feeding cows, &c. Indeed I believe it will always be beſt to do ſo; for the weeds, if there are any, are thus cut down, and the lucern thrives apace. The ſpring following, it may be harrowed with light harrows, and every year after with ſuch harrows as you find clean it beſt. Laſt autumn, when the weather was hot and dry, I ſaw a farmer harrowing Rocque's field with large ox-harrows, and I do not perceive that it is at all hurt. The weeds and trumpery were raked up, and carted to a dung-hill, with which he has this ſpring dreſſed his field, and it is now in a fine thriving condition.

Lucern makes moſt excellent hay: horſes are very fond of it, and, with one quartern of oats, I will be bound any gentleman will be well ſatisfied with the condition of his horſes, even coach-horſes; nor do I ſee it is at all more difficult to be made into hay than clover. *Muſeum Ruſticum, vol.* IV. *p.* 307.

Experiments on Lucern, by Mr. John Wynne Baker, publiſhed by the Dublin Society

The ineſtimable value of this plant has been ſo much ſpoken of by all the ableſt writers on huſbandry, that it is quite

quite unneceſſary for me to ſay any thing in its recommendation.

Here follow my experiments upon it this year.

No.
15. Sown in drills, three feet aſunder.
16. Sown in drills, two feet aſunder.
17. Sown in drills, one foot aſunder.
18. Sown in the common, or broad-caſt way.

I ſowed the ſeed for theſe experiments on the firſt of May, but the middle of April would have been a more proper ſeaſon.

The lucern began to appear on the eighth day: in its firſt appearance, it has two very ſmall leaves of an oval form.

Theſe experiments were treated in the ſame manner as the burnet.

On the ſixteenth of Auguſt, I cut the lucern of each experiment, and the produce of green fodder was as follows:

Number 15. i. e. the three feet drills, produced off one perch, thirty-one pounds and a quarter.
Number 16. i. e. the two-feet drills, produced off one perch, forty-four pounds and a half.
Number 17. i. e. the one-foot drills, produced off one perch, forty-three pounds.
Number 18. i. e. the broad-caſt, produced off one perch, fifty-nine pounds.

Upon the face of theſe experiments, the broad-caſt has the greateſt produce. Above the three-feet drills, twenty-ſeven pounds and three quarters; above the two-feet drills, fourteen pounds and a half; and above the one-foot drills, ſixteen pounds.

Hence it may be concluded, by perſons not acquainted with the nature and culture of this plant, that the broad-caſt ſowing is to be preferred, as yielding the greater produce; but I think that concluſion ſhould not be too haſtily drawn, for the following reaſons.

Theſe crops are all from the firſt cutting after ſowing the ſeed, and therefore the lucern in the broad-caſt was then as good, or probably better, than it will ever be again in any ſucceeding crop, the ground being looſer, and fewer weeds in it, than there ever can be hereafter; for the natural graſs is already riſing in it, although it was managed in the way practiſed by Mr. Rocque; which is to harrow, or rake the ground after cutting the lucern. Another reaſon is, that for the firſt year the plants are in their infancy; but in three years I apprehend the drills will more than treble their produce: whereas, at that time, I ſhould fear the broad-caſt would be quite or near deſtroved by the natural graſs. In other words, as faſt as the drilled crops improve, I do conceive the broad-caſt will diminiſh.

The culture of lucern in drills, with intervals of only one foot, I find is no better than the broad-caſt, as there is no ſuch thing as horſe-hoeing between the rows, and where the crop ſhould be large, digging would be too expenſive.

But upon the comparative experiment, between the two and three feet intervals, I confeſs I cannot ſo readily pronounce: the two feet produce the moſt, by thirteen pounds and a quarter; whether that diſtance will continue to do ſo, I cannot ſay: it may happen that when the roots become large, which is the propereſt time to aſcertain the fact, that the three-feet drills may have the greater produce: but time alone can determine this point, which really is very material to know.

Second Set of Experiments on Lucern.

Theſe experiments were calculated to diſcover how far the roots of this plant would bear being wounded, as in the culture of lucern practiſed by Mr. Rocque: I do conceive many of the roots muſt be injured, to the manifeſt diminution of the crop.

In April, 1764, I ſowed a little lucern in my garden. May the firſt, 1764, I treated ſome of the plants in the following manner, after thinning of them in the row, by taking all others from them, and leaving the plants ſingle, and about two feet aſunder.

Numb. 1. The root of this plant I ſplit from the crown of it downwards, for about an inch.
Numb. 2. The root of this plant was ſplit firſt in the ſame direction as the former, and then I ſplit it tranſverſely, for about an inch downwards.
Numb. 3. The root of this plant I cut a ſlice off one ſide, about an inch long, juſt below the crown of the root.
Numb. 4. This plant I cut the whole crown of the root off.
Numb. 5. This plant I ſplit the root of, in the ſame manner as Numb. 1. and then cut about an inch and a half off one ſide.

After wounding theſe plants, I dug the earth round them, in order to feed the fibrous roots in the nouriſhment of the plants.

They never afterwards made any figure. Towards September, Numb. 1, 2, and 3, threw out a few weak ſtems, not worth notice, but Numb. 4, and 5, never grew afterwards.

Theſe experiments I mean to repeat in a greater number, and that for two or three years together, before I ſhall venture to draw poſitive concluſions from them: but I think theſe ſeem to prove, that Mr. Rocque's method is not to be preferred ſo much beyond Tull's, Duhamel's, and M. de Chateauvieux's, as his advocates would inſinuate. But the fair trial between his method and the drill, will be to experiment carefully upon them for four or five years together; my experiments in wounding the plants, being only calculated to ſupport theory by facts; for my notion of the conſequences which muſt happen from his culture, is no more than theory.

Till I made this ſet of experiments, I confeſs I never was ſenſible of the texture and firmneſs of lucern-roots, which are really very hard to cut, and not much unlike a dried ſtick, which I muſt confeſs ſeems to favour Mr. Rocque's method, ſo far as relates to my apprehenſion of the plants being wounded by his inſtruments, which, from the hardneſs of the roots, cannot wound them in the manner I did mine with a knife. And as my purſuits tend only to diſcover the truth in matters of huſbandry, for Mr. Rocque's honour, and my own credit, I could not omit to communicate this remark, as I hope the reader will believe I am endeavouring to aſcertain the beſt culture for lucern, and not writing to leſſen Mr. Rocque or his ſyſtem: every man acting in a private capacity, has a right to adopt ſuch as he pleaſes; but I, who am acting in a great

great meaſure for the public, think myſelf bound to be conſcientiouſly exact in my ſcrutiny of every ſyſtem, which I ſhall comparatively experiment upon. If I am miſtaken in the culture of lucern, I have the ſatisfaction of conſidering ſome of the greateſt men, who have ever wrote upon the ſubject, are no leſs miſtaken than I am.

Notwithſtanding all that has been ſaid by many writers on lucern, as to its tap-roots, yet I find it has many lateral ones, and it is only a few of the plants that ſend down but one tap-root, but an infinite number in all ſhapes and directions. At a year old, I find the healthy ones are from ten to eighteen inches long; I preſerve them of that age now by me, and intend every year to take them up, in order to have them of all ages, the better to ſee their progreſs from year to year.

Upon the firſt of laſt May, ſome of my lucern, which was ſown the year before, was eighteen inches high; but let it be obſerved, that it had the benefit of a ſouth aſpect, aided by the reflection of a fruit-wall. This induces me to believe, that a declivity with a ſouth aſpect, will be the moſt advantageous ſituation for this plant, in this country; for, although lucern will live in the ſevereſt winters, yet it flouriſhes beſt under the influence of a warm ſun; the only bleſſing we ſeem to want in this country.

In the ſummer months I obſerve, in a good ſoil, and under proper culture, it grows about an inch in twenty-four hours; ſometimes I have known it grow an inch and a half in the ſame time.

Third Set of Experiments on Lucern.

The tranſplanting lucern ſeems to have been firſt thought of by the ingenious and never ſufficiently to be praiſed M. de Chateauvieux, whoſe reaſons for every new attempt are founded upon ſuch ſolid and rational principles; that they have generally ſucceeded to his expectations. This gentleman ſays, plants of two or three years old may be planted equally well with thoſe of one year old.

My plants laſt April were all one year old, which, upon taking up for the purpoſe of tranſplanting, I found differed very much in their ſize, which induced me to divide them into three parcels, *i. e.* the ſmalleſt, middling, and largeſt. Theſe I tranſplanted in the following manner, ſix inches aſunder in the rows, and the rows three feet.

Numb. 1. Forty of the ſmalleſt plants, with their tap or leading roots cut off.
Numb. 2. Forty of the middling plants, with their tap or leading roots cut off.
Numb. 3. Forty of the largeſt plants, with their tap or leading roots cut off.
Numb. 4. Forty of the middling plants, without cutting their roots.
Numb. 5. Forty of the largeſt plants without cutting their roots.
Numb. 6. Forty of the ſmalleſt plants, without cutting their roots.

Theſe ſix rows of plants were put down the twenty-eighth day of April. I watered them at the time of putting down, and once afterwards.

Very few of them died; ſo that the different ſizes and methods ſeem to anſwer equally well the firſt ſeaſon.

I intended to have cut the produce of each experiment for weighing; but a few days before that was to be done, my horſes got into the place where it grew, and eat ſome of it, which diſappointed my purpoſe. From the appearance of the experiments reſpectively, there would have been very little, if any difference in the produce; but a third and fourth year's crop will aſcertain how far cutting off the tap-roots will benefit the plants, and how far tranſplanting is preferable to ſowing. Be it noted, that the tranſplanted roots make no great figure the firſt year.

In order to aſcertain, with ſome degree of certainty, how far lucern may be worth the farmer's attention, I laſt ſummer made an experiment with an horſe, to diſcover how much he would eat, which being known, we can, from the firſt ſet of experiments, pretty exactly tell how many horſes an acre of lucern will maintain during the ſummer months. The horſe I choſe for this purpoſe is a very large one; he had been ploughing from ſeven o'clock in the morning till ſeven in the evening, during which time I forbid his having any thing to eat. When he was taken out of the plough, I ordered him to a ſtable by himſelf, where I had provided for him fifty-ſix pounds of lucern, without any other food for that night, of which he had eat by next morning, forty-nine pounds; a quantity, which I own ſurprized me.

Lucern will in this country, in favourable ſeaſons, mow four times in a ſummer after the firſt year, and we may ſafely calculate, that at every cutting it will yield half an hundred weight upon each perch, which at the four cuttings is two hundred weight upon a perch in the ſeaſon, or ſixteen tons upon an acre, *i. e.* thirty-five thouſand eight hundred and forty pounds. This is a low calculation; but at this rate, ſuppoſe five horſes to be allowed forty-nine pounds every twenty-four hours, which is two hundred and forty-five pounds, in that caſe an acre will maintain them one hundred and forty-ſix days, which is twenty weeks and ſix days. No man will contend for it, I believe, that any natural paſture will do any ſuch thing. Add to this profit, the circumſtance of making dung all the ſummer; an object, I am ſorry to obſerve, not ſufficiently attended to in this country, amongſt the common farmers; if they can make a little for their potatoes, they ſeem to think of no more.

Lucern ſhould never be ſown upon wet or ſpungy ground, but upon dry rich land, and muſt always be kept free from weeds.

I ſowed ſome laſt April in drills, upon ground not ſix inches deep, above a lime-ſtone quarry, and it grew very luxuriantly; but the ſoil is very good.

Turneps are the beſt preparation of ground that I know of for lucern, particularly if they be raiſed in drills, in the manner before repreſented.

My lucern in the broad-caſt and one-foot drills, was infected with the ruſt or mildew, during its growth; this ſeems to be an objection to the ſowing of it with ſuch narrow intervals, or in the broad-caſt way, ſince the two-feet and three-feet drills were in the ſame place, and they were not at all infected with this diſeaſe.

An Account of the comparative Advantages of cultivating Lucern, on the Drill and Broad-caſt Methods; for which the Society for the Encouragement of Arts, &c. adjudged their Premium of a Gold Medal.

The farm on which the following experiments were made, is a ſtrong clay; a ſoil, in the opinion of all writers

ters in agriculture, the moſt unfriendly to lucern. Encouraged, however, by M. Lullin de Chateauvieux's experiments, the owner was tempted to try how the lucern would ſucceed when treated in the manner he propoſes: and in the year 1761, he ſowed a field of about three acres with lucern in drills, two feet aſunder. During the firſt year, he cauſed it to be weeded carefully; and from the places where it grew too thick, he ſupplied thoſe in which it had failed. After every weeding, he cauſed the intervals to be ſtirred with a horſe-hoe, reſembling M. Lullin's ſingle cultivator, which manifeſtly revived the plants.

In 1762, the plants throve greatly, being kept clean, and horſe-hoe'd as in the former year; and the ſociety having publiſhed a premium for a comparative trial between lucern ſown in broad-caſt, and in drills, he determined to try one part of that experiment on this field, and not to beſtow on his lucern any manure whatever, or to give it any other help than the horſe-hoe.

In 1763, the plants were arrived at a ſize to yield ſo full a crop as to maintain five horſes, from the middle of May to the end of autumn, or above five months. Theſe horſes, though conſtantly worked very hard, had neither corn or hay given them during all this time; and yet they continued in ſtrength and ſpirit, and grew fat. A horſe which in May was ſo weak, and in ſo bad a ſtate of health, that it was thought he could not live, ſoon recovered, when fed with lucern. The plants were in general between three feet and three feet and a half high, at the firſt and ſecond cutting. The plants made ſo many ſhoots, and theſe ſhoots branched ſo much, that in three weeks after every cutting, or ſometimes ſooner, the intervals quite diſappeared; the whole field being ſo equally covered, that it looked as if ſown in broad-caſt. December 1763, January and February 1764, having been uncommonly rainy, the water ſtood in ſome parts of the field; and though there was generally ſuch a declivity as that it might have been carried off, he reſolved to let it remain, in order to ſee what effect it would have on the lucern. When the lucern began to riſe in the reſt of the field, in ſpring, he found that wherever the water had ſtood, the plants were killed. He ſupplied this loſs by tranſplanting lucern from other parts; and theſe plants throve very well. By a continuance of the ſame treatment, the lucern remained in a very flouriſhing ſtate: and retained a beautiful verdure and vigour, during the very great drought of the ſummer, 1765. It has yielded four cuttings every year, and ſometimes five.

Having obſerved in a root of lucern taken up in the winter, that the ſpring ſhoots had no connection or concern with the remains of the ſhoots of the preceding ſummers, but proceeded from numbers of little tubercles, with which the head of the root was ſet very thick; it appeared evident, that the plants could not ſuſtain any damage, though covered with a depth of earth during the winter. This ſuggeſted a hint, that the intervals might be plowed as deep as poſſible early in the winter, turning the earth on the beds; and that by letting the earth remain in this condition till ſpring, the clay, or ſtrong ſoil in which the lucern grew, would be mellowed, or looſened, by the winter's froſt and rain: and being harrowed ſmooth in February, the freſh lateral roots, which ſhoot out in the ſpring, would find a fine freſh mould to extend themſelves in, which muſt tend greatly to the benefit of the plants. This thought was confirmed by experiment: for the ſpring crop is amazingly vigorous ever ſince this practice was followed, and the ſhoots though of great length, and moſt plentifully ſupplied with branches, are ſo ſtrong, that no rain or wind lays them, even when they have ſtood to be in full bloom, as is the caſe with part of the firſt crop; the horſes not being able to conſume the lucern before part of it is neceſſarily in bloom. Another advantage ariſing from this practice is, that the graſs which takes root near the plants, and which cannot be otherwiſe deſtroyed but by hand-hoeing, is killed by being ſo long covered with the earth laid on the beds.

In 1761, a ſpot of ground of an exactly ſimiliar ſoil was incloſed for a kitchen-garden; and there being part of it, which was not wanted for other uſe, in the ſpring of 1762, it was ſown with lucern in broad-caſt, as a counter experiment to the former. The warmth of the garden, and the partiality of the gardener to this method, who held the field experiments very cheap, gave his lucern every advantage that could be deſired. It came up well, and was kept free from weeds; but it neither grew ſo faſt nor ſo high as the lucern ſown in drills. This difference became much more ſenſible during the ſecond and third years; for in 1764 the field lucern had got the ſtart of it ſo far, that this did not riſe to half the height, nor did it yield a quarter of the quantity of fodder; ſo that he thought it needleſs to proſecute the compariſon further.

Seeing ſo very remarkable a difference between the lucern raiſed in drills, and that raiſed in broad-caſt, he reſolved to try what ſhare of this advantage might be placed to the horſe-hoe, and what to the diſtance at which the plants ſtood; which diſtance afforded the roots more room to extend in. With this view, in 1764, he ſowed a neighbouring field in rows, two feet aſunder, intending to horſe-hoe one half, and to keep the other free from weeds by hand-hoeing only. The months of April, May, and June, of that year, were ſo dry that the plants came up thin; and the clay was become ſo hard, that the horſe-hoe could not be made uſe of till late in the year. Even with this diſadvantage there was ſeen a manifeſt difference, in favour of the plants that were horſe-hoed. The ſame difference was alſo obſervable in the ſpring of this year: but the uninterrupted drought of this ſummer has kept the clay ſo hard that the horſe-hoe could not be uſed.

Computing the rent of the land, and the utmoſt expence that can attend the horſe-hoeings and cuttings, it will be found, that feeding horſes with lucern will be a great ſaving, when compared with the price of the hay and corn, which horſes muſt have neceſſarily conſumed in the ſame time, being kept to equally hard labour.

LUG, *or* LUGG, the ſame with pole, or perch, a long meaſure of ſixteen feet and a half.

LUPINES, a ſpecies of wild pea, cultivated principally as a manure.

Lupines require the leaſt labour of any thing that is ſown; and will thrive in any ſoil, except the chalky and miry; but delights particularly in poor hungry worn out land, eſpecially if it be dry and ſandy. If ſown in February or March, after a ſingle very ſhallow plowing, and ſlightly harrowed in, or even harrowed in without any plowing, it will bloſſom three times between May and Auguſt, and prove an excellent enricher of the ground when plowed in juſt after its ſecond blooming: though Mr. Miller, holding the lupine to be a very great impoveriſher of the ground whilſt it grows, thinks it is ſtill better to parboil the ſeeds, to prevent their ſprouting, and then to ſtrew about ſixteen buſhels of them upon an acre of

land,

land, and plough them in. In warm countries, lupines are much ſown in vineyards for this purpoſe only, and are found to be one of the beſt manures that can be laid to the roots of the vines. Their ſeeds ripen towards the end of September, or in the beginning of October. They are very bitter: to remedy which, the Spaniards and Italians, who feed their cattle, horſes not excepted, with them in winter, ſteep them in river water and ſalt, till that bitterneſs is gone, and afterwards dry them thoroughly over a fire, or in the ſun. They even make bread of them, when corn is very ſcarce, and put them to ſeveral other culinary uſes. The beſt time for mowing them is after a ſhower of rain, becauſe the ſeeds drop eaſily out of their pods when they are gathered too dry. They muſt, however, be laid up very dry, or worms will ſoon breed in them. The red and the blue lupines, which are frequently planted in our gardens by way of ornament, grow wild, and in great quantities, about Madrid.

LYE, a fluid impregnated with ſalts, &c. *See the article* STEEPS.

LYNCHETS, or *Linchets*, graſs partitions in arable fields.

M.

MAD

MADDER, the Engliſh name of a plant, cultivated with great advantage in ſeveral parts of Europe, and lately in England, being a very capital ingredient in the dying buſineſs.

There are ſeveral ſpecies of madder, all of which afford a dye. M. Guettard, of the Royal Academy of Sciences, has experienced that the ladies bed-ſtraw, or cheeſe-rennet (gallium) may be made to yield one; and of this kind is probably the Ray-de-chaye, which is uſed on the coaſt of Coromandel for dying red. M. Dambourney has not, indeed, as M. Duhamel remarks, hitherto been able to extract a good colour from the gallium: but there yet remains room to hope he may be more ſucceſsful in the future experiments which he intends to make on this root.

Mr. Ray mentions and deſcribes four different kinds of gallium or mollugo, baſtard madder, which, after the laudable example of our enterprizing neighbours, ſhould likewiſe afford matter of experiment to thoſe who wiſh well to this country, and particularly to our dyers.

The azala or izari of Smyrna, perhaps more properly written hazala or lizary (according to the eaſtern method of pronunciation) which is the ſort uſed by the French dyers at Darnetal and Aubenas, to give cotton that fine carnation colour for which Adrianople is famed, is a true madder. Some ſpecies of it grow naturally under hedges and in woods; and the roots of theſe, when carefully dried, yield as fine a dye as the azala of Smyrna. M. Dambourney has cultivated a ſpecies of madder which was found growing wild on the rocks of Oiſſel in Normandy, and the roots of this plant have yielded him as beautiful a dye as the azala of the Eaſt. We ſhall hereafter ſpeak of it in his own words: but in the mean time we cannot help obſerving here, that Mr. Ray deſcribes particularly a wild madder which grows not only on the St. Vincent's rock near Briſtol, but alſo on the rocks about Biddeford in Devonſhire, and in great plenty among the hedges almoſt all over that country. As Mr. Ray calls this the *Rubia ſylveſtris monſpeſſulana major*, and as M. Duhamel ſuſpects M. Dambourney's Oiſſel madder to be that very ſpecies, it ſurely is a matter of great importance to this nation, and well worth the attention of patriots, to follow M. Dambourney's example in making proper trials of it.

The ſpecies moſt commonly cultivated is the *Rubia tinctorum ſativa*, J.B. III. 2.714. and C.B. Pin. 333, commonly known among us by the general name of madder. It is of this ſpecies that the plantations of madder are made in Zealand, and in the neighbourhood of Liſle.

The following method of cultivating this uſeful plant was ſent to the editors of the Muſeum Ruſticum, by a gentleman who has been a practical grower of madder for ſeveral years, and tried it upon land of various kinds.

My firſt trial, ſays he, was upon a ſmall piece of ground near my houſe, of about forty perches of land, lying pretty low and moiſt, of a deep mellow ſoil, and rich black mould, a little inclining to ſandy; and underneath about two feet and a half, and in ſome places three feet of good earth, was a bed of looſe ſand, with a mixture of gravel.

I have been the more particular in the deſcription of the nature of this land, becauſe it produced the beſt Engliſh madder I ever had, both as to quality and quantity.

In March I cauſed this plot to be dug a full ſpit deep; and as it was under natural graſs for ſome years before, I took care in digging to throw the top turf as low as poſſible, turning the mould uppermoſt, in order to prevent the graſs from ſpringing; which had the deſired effect. I alſo took care to throw out all the roots of weeds, and other noxious plants, which were found therein.

In this ſtate it remained about a month; then with a line I divided it into beds of five feet wide, and two feet interval

Madder.

interval between each bed, raiſing them a little in the middle with ſome of the earth in the intervals; then with iron-rakes the beds were reduced to a fine garden mould, leaving them a little rounding, like aſparagus beds, in order to ſhoot off the rain-water; and having procured ſome ſtrong packthread, at every foot diſtance I tied a ſmall piece of white woollen-yarn, and thus continued the whole length of the line, which afterwards ſerved as a rule where to fix the plants.

This line was extended, the whole length, upon the outermoſt bed, ſix inches from the ſide ridge of it; then with iron-ſhod dibbles a madder-plant was ſet ſtrong in the ground, near every tuft of white yarn fixed along upon the line.

This row being thus planted, the line was removed two feet forwards, which brought it exactly to the middle of the bed: this being alſo finiſhed, the line was again removed two feet, and planted as before; and this method I continued till the whole was planted. Thus there were three rows of plants in each bed, at two feet diſtance, and one foot apart in the rows; and the diſtance between the innermoſt row of one bed, and the outermoſt row of the next adjoining bed, was three feet.

During the firſt ſummer I kept the young madder quite clear from weeds, by hand-hoeing, as ſoon as any appeared: and in October following I took the haulm, that overran the intervals, and ſpread it over the beds, without cutting any off; then with a ſpade I covered the haulm with the earth from the intervals about two inches thick.

In this condition it remained during the winter, and in March following, the young madder came up very thick and ſtrong; and as faſt as any weeds appeared, I kept them down by hoeing, as before; but in the ſecond ſummer I found there was no neceſſity of repeating the hoeing after the middle of June, for the haulm was now grown ſo very luxuriant as entirely covered the ſurface of the ground, and thereby prevented the weeds from growing; and in October I again ſpread the haulm upon the beds, and covered it over with the earth in the intervals, as before

There are three good reaſons for covering the madder in winter.

The firſt is the new dreſſing of the beds with freſh untried earth.

Secondly, by this method deep trenches are formed at proper diſtances throughout the whole plantation, and conſequently the beds are kept dry and healthy, and thereby the roots are prevented from rotting, which otherwiſe they are apt to do, if the water continues too long ſoaking on the beds.

The third reaſon is ſtill more efficacious; for by this means the haulm is entirely rotted, and the volatile ſalts contained therein are waſhed down to the roots by the winter rains, which tends more to encreaſe the vegetation of the plants than double the quantity of any other ſort of manure whatſoever, and for this reaſon, becauſe the ſalt, inherent in the haulm, is of the ſame kind with that which was before extracted out of the ground by the growing of the madder, and is now returned into the earth again, in order to renew its former office of vegetation.

This, perhaps, may ſeem new doctrine to moſt of your readers; but experience convinces me of the truth of it, not only with regard to madder, but likewiſe in the propagation of aſparagus, which, in a future letter, I may, if I have leiſure, explain more fully, by giving the public an account of my making and managing thoſe beds.

If this hint was duly attended to, it is my opinion that both farmers and gardeners would find their account in it in the production of moſt ſorts of vegetables.

But to return more immediately to my ſubject.

In the third ſummer very little work was required, only two ſlight hoeings in April and May, owing to the ſtrength of the haulm, which covered the ground as in the preceding ſummer; and in October following the roots were taken up, and this ſmall piece of ground produced one thouſand nine hundred and ſixty-five pounds of green roots, which were very large, and the madder, upon trial, found to be exceeding good.

In cultivating madder, great care is to be taken to ſee that every ſet or plant has ſome ſmall fibres at the root; and this ought particularly to be obſerved by thoſe who are employed in taking them out of the ground; for unſkilful perſons, not uſed to the buſineſs, very often draw up ſuch as have no fibres at all, and then they certainly miſcarry.

The beſt way is, to remove the earth from the mother-plant with a ſmall hand-hoe, or ſome ſuch inſtrument; and then you may eaſily find which of the young plants has fibres, and which not.

In the ſecond ſpring you muſt be cautious not to take off above two or three ſets from each root; but in the third ſpring, when they are deeply rooted, you may take off almoſt as many as you pleaſe, without injury.

The ſooner the young plants are ſet after they are taken up, the better; and if you are obliged to have them at a diſtance, ſo that they cannot be ſet again in leſs than three or four days after they are taken up, they muſt be well watered at firſt planting, and repeated as often as you ſee occaſion, till they have taken root.

In dry ſeaſons, the young plants very often die for want of moiſture ſoon after they are planted; and in large plantations the expence of watering would be too great; therefore I always get my land ready early in the ſpring, and wait for ſome ſhowers falling; and when I find them juſt at hand, and ſometimes in the rain, I get a great many hands, and immediately go to work, ſome taking up, and others raking and planting; ſo that the whole is ſoon finiſhed, even in a large piece of ground; and when the plants are well watered at firſt, they ſoon take root, and afterwards they will ſtand a dry ſummer very well.

In the moſt favourable ſeaſons, ſome few plants always die ſoon after they are ſet; therefore about three weeks after planting, you muſt go over your madder-ground, and replace ſuch as have failed, with the beſt and moſt likely plants; and if the ſeaſon be dry, let them be well watered at firſt planting; but, if after all, you find any miſcarry, (which, in a dry ſummer, they ſometimes will do) the beſt way is to fill up the vacancies, with winter-plants, in October following, juſt before you cover the haulm.

Madder may be ſucceſsfully planted from the middle of March to the end of May, according as the ſpring is either forward or otherwiſe; but if ſhowers ſhould happen to fall in April, this is the beſt month in the year for planting madder. There ſhould be no dung of any kind laid upon the ground during the time the madder is growing, becauſe it has been found to give the madder a bad colour; and if the land is in good heart, and proper for the purpoſe, there will be no need of it.

It cannot be expected that any land, even the richeſt, ſhould produce repeated crops of madder; for which reaſon I am told, that the Dutch always allow an interval of ſix or ſeven years, in which time they manure the land very well, and ſow it with corn or garden vegetables, and have always large crops, owing to the deep ſtirring of the ground, and being clean from weeds; and I can, from my own experience, aſſert, that the beſt crops of corn always ſucceeded a madder-crop.

About five years ago, I planted an acre of madder on a light, dry, ſandy ſoil, which produced a tolerable crop, but nothing equal to the other.

I likewiſe tried it upon an acre of land of a loamy mellow ſoil, ſomewhat ſandy, about a foot deep in mould; and underneath is a cold, ſtiff clay: from this piece I had great expectations, as the plants thrived very well at firſt, but in the ſecond ſummer, when the roots reached the clay, the plants died away, and came to nothing; therefore I am well ſatisfied a cold clay is by no means proper for madder.

I have alſo, at this time, two other acres of madder, which I intend to take up next winter; it will then have ſtood three ſummers. The ſoil is a deep, hazel mould, worth about twenty ſhillings per acre. Inſtead of digging it with a ſpade, I plough-trenched it at leaſt eighteen inches deep, but managed, in all other reſpects, like the former. From the appearance it made laſt ſummer, I have no great expectations from this plantation, though, I fancy, it will be a ſaving crop.

Expences attending the Culture of an Acre of Madder, ſuppoſing the Land to be worth forty Shillings per Acre.

	l.	s.	d.
Rent for three years	6	0	0
Digging ditto at two-pence per perch	1	6	8
Dividing ditto into beds, two men one day, at one ſhilling each	0	2	0
Raking ditto, two men one day, at one ſhilling each	0	2	0
Planting ditto with two thouſand plants, one day, at one ſhilling and ſixpence each	0	3	0
Six women to take up two thouſand ditto, at ſixpence each, one day	0	3	0
Hoeing the firſt ſummer five times	0	15	0
Covering ditto in autumn the firſt year	0	6	0
Hoeing ditto the ſecond ſummer three times	0	9	0
Covering ditto in autumn the ſecond year	0	6	0
Hoeing ditto the third ſummer twice	0	4	6
To be paid in lieu of tythe, at five ſhillings per acre per annum	0	15	0
Digging ditto out of the ground	5	0	0
Total of expences	15	12	2
As I always allow my people beer when they are about this buſineſs, I may add	0	6	0
Which brings the whole expence to	15	18	2

In the above account I have not reckoned any thing for the plants, for though they coſt conſiderably at firſt, yet it is then done once for all to any perſon who continues to propagate madder, as he has always a conſtant ſupply from his own plantations.

	l.	s.	d.
Produce of an acre of madder	52	12	2
Expences	15	18	2
Clear profit	36	4	4

In the buſineſs I follow, which is that of a clothier, a great deal of madder is uſed in dying; and being of opinion that there are many uſeful diſcoveries now lying dormant, only for want of proper methods to bring them to light, I determined to try an experiment on madder; accordingly I took twenty pounds of the green root, and having waſhed it clean from dirt and filth, I bruiſed it in a large iron mortar, juſt before uſing, and with other ingredients I dyed half a pack of wool of a dark, full drab: upon examining my colour, I found it full as good as tho' I had uſed four pounds of the beſt umbro madder, imported from Holland; ſo that, according to this calculation, which is founded on experiment, five pounds of green madder-root is equal to one pound of dry manufactured madder: and as I have found this method to anſwer I have continued to uſe the root in this condition ever ſince, and find it much the beſt and cheapeſt way; for the green root is bruiſed very eaſily in the mortar, and thereby ſaves a great expence in drying, pounding, &c.

Before I quit this ſubject, I would adviſe thoſe perſons who are inclined to cultivate madder, to be very cautious in the choice of land for this purpoſe; for hereon their ſucceſs chiefly depends. Madder being a plant that draws a great deal of nouriſhment, conſequently the richeſt and deepeſt lands are to be choſen, and ſuch as lie pretty low; for high lands are ſeldom fertile.

The following method of cultivating madder, was communicated to the public by M. de Salens, a French gentleman, who is well acquainted with this branch of huſbandry.

I am apt to think, ſays he, there is hardly any kind of ſoil, but what madder will grow in; but it does not thrive alike in all: on the contrary, ſcarcely any plant ſooner diſcovers the richneſs, or poverty of land, by the ſtate of its growth, than madder: in rich land, and a ſoil that agrees with it, it is luxuriant, and produces a great number of ſizeable, well-conditioned roots; but in a poor, dry, hungry ſoil, the plant is viſibly checked in its growth, and the roots of it are ſmall, and few in number.

Madder is a great friend to moiſture, and therefore thrives beſt on a good loam, with a clay bottom. It is very fond of freſh land juſt broke up; but it muſt be ſo ſituated as not to be ſubject to be overflowed, as that will deſtroy the plant.

Madder requires, to come to a ſtate of perfection, a great deal of nouriſhment; yet it is ſaid not to impoveriſh the land; and this, in fact, is evident; for when the madder is dug up, the land will be in excellent condition to bear a good crop of wheat.

I have tried ſeveral ways, and at length am of opinion, that the beſt method of raiſing madder in France, is from the ſeed: it occaſions, indeed, at firſt, ſome delay; but by continuing to ſow a quantity in the nurſery every ſpring, you will never fail of having plenty of plants.

The ſeed muſt be ſown on a bed of earth, dug well, and made very fine by the rake, with which inſtrument the ſeed muſt be ſlightly covered.

When

When the plants appear, they muſt be carefully weeded, and ſet out with a hoe: the bed muſt, during the whole firſt and ſecond ſummer, be kept very well hoed, and clear of weeds; and, if this is done, they may be planted out the ſecond autumn.

I have many reaſons for preferring this method in France; but I ſhall forbear giving a detail of them, becauſe my opinion with reſpect to planting madder in England, is different.

The ſeed of madder does not ripen ſo well with you, as with us; neither does it, as I have been informed, take ſo well on being ſown. For theſe reaſons, I would recommend it to you, to make your plantation with ſhoots that are put forth by the old roots in ſpring. I have practiſed this method, and met with ſucceſs.

For madder to ſucceed well, there ſhould be a great depth of good ſoil, and it ſhould be turned up very deep with a plough, or, what is much to be preferred, with a ſpade. When the ground is properly prepared, it ſhould be planted with ſets, being the ſpring ſhoots pulled up in a madder-plot, with ſome root to them; for, if they have not ſome root and fibres, they will not take kindly: theſe ſhoots generally come from the layers of the plants, and great care ſhould be had in taking them up, or the crop of madder will be damaged: the beſt way of doing it is with a dibble that has a flat edge ſhod with iron; this, on being thruſt into the ground, cuts off the roots at a proper length, and by gently declining the handle of the dibble, raiſes the ſet, without injuring the fibres of the root; and great care ſhould be had not to take up too many of theſe ſhoots, or ſtalks, as they are undoubtedly neceſſary to the ſupport and thriving of the principal roots, which, were they deprived entirely of their ſtalks, would certainly periſh.

It is ſcarcely neceſſary to inform you, that as faſt as theſe ſets are taken up, they ſhould be immediately replanted.

To make the method of planting theſe ſets more intelligible to you, I muſt obſerve, that they are planted nearly as potatoes are planted in Ireland; that is, a ſtraight furrow is drawn, the ſets are put into it, the earth of the ſecond furrow is thrown over them, the ſecond furrow is filled up with ſets, &c. and ſo on till the whole ground is planted.

We place the ſets here within three inches of each other; but this I think is too near for good land: perhaps they would thrive better, was double the ſpace allowed: when three rows are planted a foot aſunder, we leave an interval of four or five feet, according to the ſtate of the land.

Grounds planted with madder, always ſucceed beſt when gentle rains fall ſoon after the work is done, as the ſets take root the readier, and the whole gets into a thriving ſtate.

In Holland and Flanders, their method of planting differs from that above deſcribed: they take up their ſets from an older madder ground in May, and they plant them again immediately with a dibble, about three inches aſunder, in rows about fifteen inches from each other; they form their beds about ten feet wide, and leave intervals of only one foot and a half, or thereabout.

The beſt time of planting a madder-ground is undoubtedly in autumn, as the ſets are then beſt furniſhed with roots, and the rain, which commonly fall at that ſeaſon, forward their growth.

As the ſtalks of the madder-plants are to be laid down and covered with earth, the intervals ſhould be every now and then ſtirred to keep the ſoil looſe. This covering is done when the ſtalks are about fourteen or fifteen inches long: after the ground has been well cleared of weeds, a part of the ſhoots in each row are laid down in the intervals on the looſe earth, and ſlightly covered with the ſame earth; obſerving, however, not to cover them entirely: the end of each ſhoot ſhould be left out of the ground, or they will not grow, and the whole work would be thrown away. The intention of laying theſe ſhoots down is, that they may be converted into roots, and thereby increaſe the quantity for ſale; but all the ſhoots ſhould not be laid down, or the diſproportion betwixt the ſtalks and the roots would be too great.

This work may be done with great eaſe with the common implements: let a furrow be opened cloſe to each ſide of the bed with a plough: in theſe the ſhoots are laid down, and covered ſlightly with a hoe.

None of the ſtalks of the madder ſhould be pulled up the firſt year, as it would too much weaken the roots by diſturbing them, and tearing off their fibres.

After laying down the ſhoots the firſt year, the madder-ground requires no farther care, except being kept clear of weeds; and in the autumn of the ſucceeding year it may be taken up, in order to its being prepared for ſale: the earth of the intervals muſt always be kept looſe by tillage.

When the madder-roots are taken up, the whole land gets a thorough ploughing, and ſome freſh roots or ſets are regularly planted in rows, in the intervals of the former year; and when this ſecond crop of madder is off, the land will be in fine condition to bear excellent crops of corn; for madder is no impoveriſher of land, and the frequent tillage it requires, brings the land into fine tilth, reducing it into as ſmall particles as the bed of a well-kept garden.

The beſt huſbandry is, not to plant the ſame land in madder for many years afterwards; and whenever it is again planted with that crop, it ſhould be well dunged, manured, and tilled the preceding year.

When the ſtalks begin to wither, that is, about the latter end of October, the roots are to be taken up; and the cheapeſt and ſhorteſt way of doing it, is to looſen the earth with a common plough, firſt taking off the earth-board and coulter: when the earth is thus looſened, women and children may ſerve to pick up the roots; and whatever difficulty occurs, the labourers turn up the ſoil with their ſpades.

But a much better, though rather more expenſive method is, to have the earth of the beds turned into the intervals with a three-pronged fork: by this method the roots are taken up almoſt without damage; and many which lie a little deep are ſaved, but which would otherwiſe have been left in the ground and loſt; and particularly moſt of the vertical or tap-roots are got up.

When the roots are taken up, they are dried as much as poſſible in the air, afterwards carried to a kiln, and laſtly to the mill to be ground.

A light loamy ſoil is better for madder than a rich ſtrong clay; it loves moiſture, but is killed if it is overflowed: therefore, if the ſoil is in other reſpects proper, but too wet, it muſt be firſt drained, or at leaſt the beds muſt be raiſed high, and the intervals ſunk low: on the other hand, if the land is too dry, the intervals may ſafely, and even profitably, be raiſed above the beds: this will at leaſt

prevent the young freſh planted ſets from being hurt by too much drowth.

When the upper ſtratum of ſoil is deep, it is to be obſerved, that the land cannot be ſtirred too deep: the only thing to be apprehended is the expence of doing it: the more the earth is reduced, the more nouriſhment will it afford to the roots of the madder; they require a great deal; but in general madder pays well for any labour that is beſtowed on it.

Dry weather is, if poſſible, to be choſen for taking up madder roots, as the earth then eaſily falls off them, and they need not be waſhed, which is to be avoided; and, in fact, there is no occaſion to waſh them, unleſs they grew in a ſtiff ſoil, and the weather was very wet when they were taken out of the ground.

Some judgment is required reſpecting the time of taking up theſe roots: I have already mentioned that they will, in general, be fit for uſe by the latter end of the ſecond autumn: but this is not always the caſe; and it is much better to let them lie in the ground another year than to ſpoil a crop.

The Dutch often take them up too ſmall, and the French almoſt as often let them grow too large. The two extremes are equally to be avoided: the proper time to take them up is, when they are about the ſize of a ſwan's quill; they then yield moſt dye, and are of courſe moſt proper for uſe. The time when they arrive at this proper ſtate, depends not only on the nature of the ſoil in which they have been planted, but alſo on the good huſbandry that has been beſtowed on the land; for without proper tillage they will turn out but an indifferent crop; but if they are planted on a good loam, are well tilled during their growth, and have favourable ſeaſons, they need never be left in the ground longer than the end of the ſecond autumn, whether they are planted in the ſpring or the autumn.

I have mentioned in this letter many things which will appear trifling to you, when experience has made you more knowing in this culture; for, depend upon it, a greater portion of knowledge is acquired by a little experience than by a great many precepts; the firſt makes a deep impreſſion on the mind, whilſt the latter are ſoon chaſed away by new, and perhaps more pleaſing ideas.

I would recommend it to you, when you begin to plant madder, to depend more on the judgment you ſhall form of things, than on any thing you can read on the ſubject. If you miſcarry in ſome inſtances, you will certainly rectify matters in your future practice: a ſenſible man cannot be long in the wrong.

I have not, I know, given you any ſyſtematical inſtructions in the affair of cultivating madder; and this I purpoſely avoided doing; for, had I attempted telling you in what manner this uſeful plant ought to be cultivated in England, I ſhould certainly have miſcarried, and all I could have ſaid would have amounted only to probable conjecture: had I, on the contrary, given you a circumſtantial detail of our methods of practice here in France, it would only have ſerved to miſlead you, ſo much do the climates of the two countries differ. I am therefore in hopes, that my manner of treating the ſubject will be not only more agreeable, but more uſeful to you, as I have, for the moſt part, only mentioned ſuch circumſtances as may be equally uſeful in the culture of this plant in both countries.

Lay it down as a maxim, that the culture of madder, if properly managed, is very profitable; there are few crops pay better; but when the two extremes are to be carefully avoided; we muſt not let our expences be ſo large as that no crop will repay them; neither muſt we be ſo ſparing as to baulk the growth of the plant for want of proper tillage. A great deal is required, yet too much may be beſtowed on it, for the reaſon above-mentioned: the golden mean is beſt in this, as well as in all other matters; and what this mean is, can only be learnt from experience; for it is abſolutely impoſſible to lay down maxims that will ſuit all countries, all climates, and all ſoils.

What has hitherto been ſaid relates to the common way of cultivating madder; we therefore ſhall now give in his own words, the great improvements made in this article by the ingenious M. Dambourney.

"M. Rondeaux, ſays he, found, eight or ten years ago, on the rocks of Oiſſel, two plants of madder, which he took up and ſet in his botanic garden. He afterwards gave me ſome ſlips of them, and I planted them in a ſimilar place, out of curioſity: but M. Du Hamel's treatiſe ſoon made me perceive the importance of cultivating this plant. I accordingly applied myſelf to it: and by following all the methods which had been pointed out to me, and thoſe which ſeemed to coincide with them, I ſucceeded ſo far as, in four years, to have plants enough to try this culture in the open field. In the mean time I learnt that M. Peter Dupont cultivated with ſucceſs, at Elboeuf, plants of madder which he had received from Liſle in Flanders. He was ſo kind as to make me a preſent of an hundred ſets of them; and this little reinforcement, added to what I had raiſed of my own, obliged me to ſeek for room in my garden at Oiſſel, wherein to extend this culture. Finding no other ſpot vacant there, but two walks, I ſacrificed the pleaſure of enjoying them, to my then new and prevailing inclination. I therefore dug up one of them, the ſoil of which is a yellow and ſandy clay, underneath which, at a ſpade's depth, is a bed of large gravel, cloſe knit with very ſtrong earth: but I did not ſuffer this to be broken into. I divided the walk lengthwiſe, and, without dunging it at all, planted in December 1757, in one half of it, firſt the ſets which I had received from Elboeuf, and then immediately after, but without mixing them, thoſe which I was able to take from my own plantation. The other half of the walk was ſowed in the month of April 1758, with ſeed which I had gathered from my own plants. The other walk was diſpoſed of in the ſame manner, as faſt as I could get plants or ſeed to ſtock it; taking care the firſt year to keep my beds well weeded, and to lay down the branches as faſt as they ſhot out.

"So early as in the autumn of 1758, I gathered ſeeds from my plants of Oiſſel madder, whether raiſed from ſeeds or from ſlips; but that of Elboeuf had not then bloſſomed, though it had put forth ſtalks three feet high; and even in 1759, it produced bloſſoms on only a few ſtalks, whilſt the Oiſſel madder was loaded with them. When the ſtems were withered, I had the curioſity to take up ſome of the roots, and was thereby informed of the following intereſting facts.

"1. Though it is ſaid poſitively, in the Dictionnaire Encyclopedique, that madder raiſed from ſeed requires five years to grow to the ſame ſize as that which is raiſed from ſlips attains to in eighteen months, yet I found all things

equal

equal in this reſpect; and if there was any ſort of advantage on either ſide, it was in favour of that which had been ſown: both the one and the other occupied the whole depth of the ground ſo far as it had been looſened, and their roots had, in ſeveral places, penetrated through the hard bed of gravel underneath: but in order to pierce through it, three or four roots had twiſted themſelves together, and ſhaped themſelves exactly to the form of the paſſage they found between the pebbles, in conſequence of which they were more or leſs choaked there; though they afterwards reſumed their natural ſhape and plumpneſs in a bed of ſmall pure ſand which lies underneath the hard bed, and in which I have been obliged to leave ſome of them at the depth of four feet.

"It is plain therefore, from this inſtance, that no time is loſt by raiſing madder from the ſeed, and that this plant may be raiſed ſucceſsfully in the moſt indifferent ſoils, even without the help of dung.

"2. I took advantage of ſome fine days to dry in the ſun, but ſeparately, the roots which I had taken up. Every thing ſeemed to give the preference to thoſe of the Elboeuf ſpecies. They were larger and redder than the others, and their powder was finer to look at: but the effect proved very different. To make a fair compariſon of them, I dyed, with equal quantities of each of theſe ſorts of madder, two equal parcels of cotton prepared in exactly the ſame manner: that which was dyed with the madder originally of Oiſſel took a much brighter colour, and reſiſted during thirty minutes a boiling which the other could not bear during ten. I likewiſe compared its effect with that of the Lizary or Hazala of Smyrna, and the advantage, as well in point of brightneſs as of the durableneſs of the colour, was alſo on the ſide of the Oiſſel madder.

"This valuable kind appeared to me from that moment to deſerve the preference. In the ſpring of 1760 I ſowed all the ſeed I had of it, part upon hot-beds, and part on beds in my kitchen-garden; and I deſired M. Rondeaux to help me to find out more plants of it upon the rocks of Oiſſel or of Orival: but he aſſured me that he had ſearched for ſuch ſeveral times, in vain: nor was he more ſucceſsful in a journey which he took thither laſt Auguſt, with M. Dangerville.

"I therefore determined to have recourſe to the ſuckers which grow around theſe plants: but though I took them up as carefully as poſſible, I could ſcarcely get any that were rooted; and notwithſtanding that moſt of thoſe which I did plant were yellow for the length of from four to eight inches, yet nine of them in ten died. The offſets of the Elboeuf madder, on the contrary, though taken up with but little precaution, have a great many fibres and young roots, and their taking freſh root is ſure, provided they are planted in cool weather. Nature ſeems then to compenſate the cultivator for the ſcantineſs of the ſeed which this laſt ſpecies produces, whilſt the other yields it in abundance.

"Not to neglect any means of multiplying the Oiſſel madder, I dug up a ſmall ſpot of it, about the fifteenth of laſt June, and took from thence all the ſlender roots which run in great plenty juſt below the ſurface of the ground: I cut them into pieces at every ſecond joint, and planted them the ſame day in channels, where all theſe that were brown and woody became good plants, and thoſe which were then only yellow and tender rotted.

"The doing of this taught me what I had not learnt from M. Hellot's memoir, nor had any of my correſpondents in Holland informed me of it; namely, from what part of the root it is that the moſt valuable colour is obtained. After all my runners were thus taken off, and replanted, there ſtill remained the ſtock furniſhed with lateral and with deſcending roots, reſembling in form and colour large earth-worms. In three days of ſun-ſhine they were dry, and the parenchymæa, or pulpy part of the root, being then leſſened in bulk, the outer ſkin became wrinkled, becauſe it was then too large. To clear them of this wrinkled ſkin, I had recourſe to a method firſt thought of by M. Paynel of Darnetal, which was, to put theſe roots in a large ſack of coarſe canvas, and to ſhake them ſtrongly therein. The friction of the ſack, and of the roots one againſt another, took off almoſt all that outer ſkin, which I afterwards ſeparated by winnowing, and what then remained was that which alone ought to be called fine and true peeled bunch madder, the effect of which is as ſuperior to that of the azala, as the azala is ſuperior to the fineſt Dutch madder. I would not however adviſe the cultivators of madder to follow this method, any farther than there may be curious and nice buyers ready to give them a price proportioned to the expences it occaſions.

"By thus taking up each ſpecies of madder in the ſpring, one has, as M. Du Hamel gives room to hope, not only the advantage of obtaining ſuckers and joints of roots for raiſing new plants, but alſo, if the ſeaſon be not quite unfavourable, one may dry the root itſelf in the ſun ſufficiently to make it keep, and by this means the expence of drying it with fire in a ſtove is ſaved, and the injury which the fire does to the quality of the madder is avoided. The colouring part would be ſtill more valuable, if the root were dried in the ſhade under a ſhed open on all ſides; and to accelerate this drying, I have ſucceſsfully made uſe of a bed of half-baked bricks, upon which I have ſpread the freſh roots. A bed of dry aſhes, ſix inches thick, may alſo be uſed: but in this caſe it muſt be covered with cloths upon which the roots muſt be laid, that the aſhes may not mix with them when they are turned. A floor of plaiſter likewiſe facilitates this drying; and I believe it far preferable to bricks, on account of the ferruginous parts which theſe generally contain.

"The principal difference which diſtinguiſhes the Oiſſel ſpecies is therefore obſervable in its roots, which are ſlenderer, of a leſs bright colour, leſs furniſhed with fibres at their joints, and thoſe joints farther aſunder, than in the Elboeuf madder: but, beſides this, an attentive eye will diſcern many more diſtinguiſhing marks.

"In the ſpring of the ſecond year it riſes ten or twelve days earlier than the other ſorts, its ſtalks are ſlender, and they trail upon the ground as ſoon as they are a foot long; its leaves are of a pale green, long, narrow, thin, waved along, their edges (pretty much like that of the laurel); its bloſſoms are diſpoſed in looſe ſpikes, and each of the ſeeds which ſucceed thoſe bloſſoms ſtands upon a pretty long foot-ſtalk.

"The Elboeuf madder, which came originally from Flanders, and is the ſame as the Flemiſh refugees carried into Holland, puts forth, on the contrary, ſtrong ſtalks, which have frequent joints, and are able to ſupport themſelves even when they are two or three feet long. Its leaves, which are of a deep green, are thick, broad at their baſe, and terminate in a point almoſt like the leaf of the

the great mirtle, and they are not at all, or very little, waved. It does not bloſſom till the ſecond or third year: its flowers are very apt to fall off, and when this accident does not happen, its ſeeds ſtand on ſhort foot-ſtalks. This ſeed grows very well: but the eaſe with which well rooted ſhoots are obtained from this ſpecies renders it the leſs valuable.

"In order to enlarge my plantation, and likewiſe in hopes of enriching it with a new ſpecies, I wrote to Smyrna for ſome ſeed of the azala or izary, and luckily received three pounds of it on the 20th of Auguſt 176c. It ſeemed to be abſolutely like that of the Oiſſel madder, and I ventured to ſow a ſmall part of it, on the 27th of Auguſt, upon an old hot-bed which had loſt all its heat. It roſe well, and the young plants were not injured by the winter. I tranſplanted them into open ground at the end of laſt February, they are now in bloom, and their appearance is exactly like that of the Oiſſel madder, excepting that their ſtems are ſlenderer.

"As to the culture, I ſet out with ſcrupulouſly obſerving M. Du Hamel's directions: but afterwards I ventured to deviate from them in ſome points, in order to adapt it to the leſs attentive genius of our farmers. In the firſt place, I have experienced the truth of what M. Paynel of Darnetal obſerved to me, viz. that the plants which are raiſed from layers, at a great expence, produce only long woody roots, which yield hardly any colour, remain hollow during two years, and produce very few of thoſe vermicular roots, which are the only valuable ones. I have therefore quadrupled the number of plants in given ſpace; the ground has been well filled with them, and the expence of making layers has been ſaved; and, thoroughly to accommodate the culture of this plant to the practice which our country people are accuſtomed to, I have either planted the ſlips, or ſowed the ſeed, in rows after the plough, as is done for kidney-beans, and the workman uſed to earth up theſe performs mechanically the ſame operations for the madder, the expence of cultivating which in this manner is no more than that of raiſing thoſe beans in the field.

"Having obſerved that the eaſt winds in the ſpring, and the heat of ſummer, are equally fatal to whatever is then ſet in the lands about Oiſſel, and that, on the contrary, whatever will bear planting in the autumn ſucceeds very well in them; I took up in October laſt all the plants of two years old madder that were in my garden walks, and theſe afforded me as many ſlips as were ſufficient to plant half an acre of ground. Very few of them failed, becauſe they were all brown and woody. But as the roots which are taken up in autumn, and which one might wiſh to be able to keep, cannot be dried without fire; it is adviſable to dig up in that ſeaſon only the quantity neceſſary to furniſh ſets for replanting, and from June to September to take up what is intended for ſale.

"On the 16th of laſt February I ſowed in a hot-bed the greateſt part of the Lizary ſeeds which I had received from Smyrna, and the reſt of them a fortnight after in one of the beds of my kitchen-garden. I raiſed from them plants enough to ſtock four hundred and forty ſquare feet of ground, in an open field, where they ſucceeded perfectly well: but this tranſplanting checks their growth; ſo that if the ſeed is ſown in the field in May, the crop will be in nearly equal forwardneſs: but I have not had cauſe to approve of ſowing it earlier in open ground.

"As it is right to make even inconveniencies become leſſons of inſtruction, the impoſſibility of drying without fire the roots which I took up in October, put me upon trying to uſe them freſh, in the ſtate they were when dug out of the ground. I therefore waſhed them well, that no earth might remain upon them: but having myſelf experienced that, as M. Du Hamel obſerves, this root loſes ſeven eights of its weight when it is dried ſufficiently to be reduced into powder, I judged that I muſt proportion my quantity accordingly. I therefore put into a quantity of liquor which would have required a pound of powdered madder, eight pounds of freſh roots bruiſed in a mortar, and with this I dyed ſome cotton, in the uſual way. When the dying was finiſhed, I found that the liquor was ſtill over-charged, though the cotton had imbibed ſo deep a dye as to require two boilings to bring it down to the uſual colour: upon which I repeated the experiment with ſix pounds, and afterwards with four pounds, and I found that this laſt proportion of undried roots is that which gives a colour equal to what is extracted from a pound of dried and powdered madder. One half of the quantity of roots commonly uſed may therefore be ſaved by dying with them when they are freſh dug: but, though this is a great ſaving, it is not the only one.

"1. There is no need to build kilns or ſheds for drying the roots in changeable weather.

"2. One is exempted from the inconveniences of a too haſty or too ſlow drying, either of which is equally hurtful to the quality of the madder.

"3. The waſte occaſioned by the peeling, garbling, winnowing, &c. of the roots, in the doing of which many, if not all of the ſmall ones, that are not for example thicker than ſtraws, are ſeparated with the refuſe parts, and thereby generally loſt, is hereby ſaved.

"4. The expence of grinding is ſaved, together with the waſte and fraud which may be committed at the mill; and likewiſe the inconvenience of waiting till the mill is at liberty, which is of no ſmall conſequence in places where there are not mills appropriated to the grinding of madder only.

"5. Laſtly, the roots thus uſed do not evaporate or ferment, as the powdered madder always does if it be not ſpeedily uſed.

"All theſe advantages put together may be deemed equivalent to a ſaving of five eights in the quantity. The planter who knows how to dye may reap the benefit of them the moment that his roots are large enough to be taken up: the dyers by trade will by degrees be ſenſible of the advantage, and ſhare the profit of the planter, when the madder grounds are nearer them: they will even find themſelves under a neceſſity of ſo doing whenever this method ſhall become general, and this will be a means of rendering it ſuch; for as there is no particular time to be waited for in order to the madder's acquiring maturity, after it has been planted eighteen months; the huſbandman who carries a parcel of freſh roots to market will be ſure of ſelling them in that ſtate, and the dyer may buy them daily, in proportion to the quantity he wants; or he may agree with the planter for ſuch and ſuch quantities to be delivered to him at ſuch and ſuch times. I have moreover experienced that theſe roots may be kept freſh during ſeveral months, by laying them in a hole three feet deep, in alternate layers of roots, and of earth.

"This experiment pleaſes me again in its tending to leſſen the expence of dying, and conſequently to reduce the price of our dyed ſtuffs at foreign markets, by which means our trade with other nations may be benefited: and

it

it is likewiſe new, ſince neither M. Hellot nor M. Duhamel have pointed it out. I have alſo experienced that the Elbœuf madder is very good when it is uſed freſh; a circumſtance by ſo much the more important to be known, as this ſpecies is not only the longeſt lived of any, but alſo the moſt eaſily propagated.

"The principal difficulty now remaining for me to ſurmount, is to find out ſome cheap and eaſy way of taking up the madder, without leaving in the ground its deſcending roots, which yield the beſt colour; for the method which I have hitherto practiſed has been conſiderably expenſive. M. Duhamel propoſes a plough which turns over the earth, without a coulter: but if I may judge from what I have ſeen, this expeditious inſtrument can ſuit none but lands where a clayey bottom hinders the vermicular roots from piercing deep. I wrote to Holland, to know how the Dutch manage in this reſpect: but thoſe zealous patriots are very reſerved in every thing relative to this plant, of which we let them be the monopolizers: I was anſwered, that they uſe the ſpade and the fork. However, I ſhall try what my zeal and what incidents may ſuggeſt to me, and ſhall communicate whatever I may find to anſwer beſt.

"An objection which may, perhaps, be ſtarted againſt this branch of huſbandry in France, is that there may be danger of its prejudicing that of our corn, which is an article of the greateſt neceſſity. But beſides that we have immenſe tracts of uncultivated lands where it might be eſtabliſhed, I can, with M. Duhamel, aſſert, that the profit of the madder may be had in the beſt fields of this province (Normandy) without diminiſhing the crops of the moſt valuable corn. In effect, it remains in the ground but eighteen months, and after it is taken up, a ſingle ploughing is ſufficient to enable the land to produce very fine wheat, without any manure. Now it is the cuſtom in all our wheat grounds to take a crop but once in three years, and this may be had after the madder. Nay, an advantage may be reaped even in the firſt year, by ſowing, between the rows of madder, onions and other pot-herbs, which do not root deep or occaſion much ſhade: but there will be a ſtill greater profit in making it grow jointly with kidney-beans, becauſe, the rows being regular, nothing would hinder the after-ſtirrings, which contribute ſo much to promote vegetation."

M. Dambourney continued his experiments on madder, and gives the following account of them.

"I have reſtricted myſelf to the three ſpecies which yield the brighteſt and moſt laſting colour: theſe are, the madder originally of Oiſſel, that which is ſometimes found growing wild in the vineyards of Poitou, and the lizary or hazala of Smyrna. All theſe bear ſeed in their very firſt year, and in the ſecond one may gather two thouſand ſeeds from a plant which would not afford at moſt above twenty or thirty ſlips. The difference between theſe means of propagation is ſtriking, and ought to be deciſive in all countries where the ſeed ripens well, as it does in almoſt every part of France.

"The manner of raiſing it from the ſeed, as practiſed by me, is thus. Along a wall which fences off the north wind, let a trench be dug two feet deep, five feet wide, and of ſuch length as may be moſt convenient; then, towards the middle of February, let it be filled with hot dung of horſes or mules, well preſſed down, to within about three inches of the level of the ground, and afterwards fill it quite up to the top with fine mellow mould, preſſed down gently, and laid ſmooth with a rake. A bed of this ſort is preferable to any other, becauſe a common labourer can make it very well, whereas it would often be neceſſary to have recourſe to a gardener to make a raiſed hot-bed. The expence is not to be regarded, becauſe this bed may be ſown ſix times in a year, and the mould which may be taken from it afterwards will be worth as much as the coſt of the dung. The uſing of this bed does not at all prevent ſowing likewiſe in the beds of a kitchen garden: but as this laſt ſhould not be attempted before the middle of March, for fear of froſts, there will be a great advantage in ſowing upon the hot-bed; for a month gained in this ſeaſon is invaluable.

"On the 20th of February, 1762, I ſowed upon ſuch a bed ſome madder ſeed in ſmall channels about an inch deep, and three inches aſunder. This method is always preferable to ſowing in broad-caſt, becauſe the ſeed is better covered, and the weeding is more eaſily performed. The young plants appeared after nineteen or twenty days, they were watered and weeded when neceſſary, and on the 30th of April they were fit to be tranſplanted into open ground.

"As moſt of our farmers are, unhappily, not able to advance money for a culture from which they have no proſpect of reaping a return in leſs than eighteen months, I tried, laſt year, what would be the event of ſowing madder at the ſame time as kidney-beans, and in the ſame furrows of the plough. The beans, which riſe in leſs than eight days, required to be earthed up when the madder had ſcarcely appeared above ground; and this operation ſmothered the madder entirely. I therefore judged it moſt proper, this year, to ſubſtitute my young hot-bed plants of madder in lieu of the ſeed; and accordingly, when the weather was moiſt, for that is an abſolutely neceſſary circumſtance, I ſet ſome of my people to plant a piece of ground which had been well prepared for a crop of dwarf-beans. In each furrow of the plough where theſe beans were ſown, women and children placed the young plants of madder ſix or ſeven inches aſunder, fixing the root in the bottom of the furrow by means of a handful of earth put around it, and reſting the green ſtem againſt the ſide of the furrow, the ſurface of which it exceeded by at leaſt one row of leaves. The ploughman ſtopped a little at the end of the furrow, till the whole of it was planted: he then opened with his plough, which had a ſhifting mould-board a ſecond furrow, in which nothing was either ſowed or planted; and at the ſame time the earth turned out of this filled the firſt. A woman finiſhed this filling with a rake, as well to cover the beans completely as to earth up the plants of madder. The third furrow was ſowed and planted like the firſt, and this was continued till the whole extent of the ground was planted in rows fifteen inches aſunder. This work, which did not in the leaſt alter the common method of cultivating the beans (excepting that only two thirds of the uſual quantity of ſeed were uſed) was performed in five hours, by one ploughman, three women, and three children. The ground thus planted contained upwards of twelve thouſand ſets of madder; and theſe had taken freſh root, and had begun to ſhoot up when the beans roſe. It was weeded twice, its ſurface was ſtirred, and the plants were earthed up as uſual, without any danger. Both throve well together: the beans were pulled up when they were ripe, and the madder, now ſole poſſeſſor of the ground, covers it like an artificial graſs. The greateſt part of it

has

has yielded a little ſeed. The crop of beans, notwithſtanding the drought of this ſummer, is a'moſt equivalent to the expences, and next year I ſhall have that of the ſeed and roots of the madder, at the expence of only a ſtirring of the ſurface and a ſingle hoeing in the ſpring.

" My hot-bed was no ſooner cleared, than I ſowed it again with madder: but the extraordinary drought of the ſeaſon obliged me to leave it there till the 6th of Auguſt, by which means I loſt a crop. I then took advantage of a rainy day to tranſplant it: and this was done in the ſame way as before, excepting, that the ſeaſon was too far advanced to admit of ſowing beans at the ſame time. The length of the roots of the madder likewiſe required more precautions to fix them with earth at the bottom of the furrow, in which one of the horſes being forced to tread in order to open the next furrow, the whole would have been trampled to pieces, or dragged out of the ground. Yet the ſame number of work people as before-mentioned, ſet ſixteen thouſand plants in ſix hours. The ſpot is well filled, and the plants will be ſtrong enough to reſiſt the winter.

" On the 15th of May, being deceived by a ſmall rain, I ſowed near an acre of ground in alternate rows, as is practiſed for beans, but only with madder. I uſed for this purpoſe three quarts of ſeed, which I have much regretted; for the conſtant drought has hardened the ſurface of the earth ſo that the young plants have not been able to pierce through it, and conſequently all has been loſt. The method which I am now going to relate will prevent this inconvenience hereafter.

" I ſowed my hot-bed, for the third time, on the 6th of Auguſt, with a deſign to let the young plants remain there all the winter, and not to tranſplant them ti l the end of February: but the nineteen or twenty days which this ſeed requires, in order to its ſprouting, diſconcerted me. It was neceſſary, in that hot ſeaſon, to water frequently by hand, and this, beſides wearing out the gardener, laid bare ſome of the ſeeds, which grew no more. It then occurred to me, that this might probably be remedied by ſowing ſeed which had already began to ſprout. Accordingly, I filled the bottom of the box with moiſt mould a quarter of an inch thick, then covered this entirely with ſeeds, and ſo proceeded in alternate layers, the laſt of which was of mould. I kept this box well watered, though expoſed to the ſun, and each day I examined the progreſs of the ſeed. It was on the eighth that the germ began to appear, and the very next day it was three quarters of an inch long. I ſeized that inſtant to lay in channels made in the hot-bed both the ſeed and the mould in which it had ſprouted: I then ſmoothed the ſurface of the bed, and two days after all the rows appeared diſtinctly. This method likewiſe ſaved me a weeding, which I had generally found to be neceſſary as ſoon as the ſeed which had not been made to ſprout before-hand had riſen. The growth of the young plants was ſo rapid, that inſtead of letting them remain there all the winter, as I firſt intended, I ventured to tranſplant them into open ground on the 14th of laſt September. Froſt is a little to be feared for this laſt plantation: the event will be a leſſon for the future.

" Eight days before theſe plants were taken up, I laid another parcel of ſeed to ſprout, in the ſame manner as before, and therewith immediately replanted my hot-bed. It has riſen well, and will paſs the winter there. I hope (by thus uſing ſprouted ſeed) to be able next year to raiſe at leaſt ſix crops on the hot-bed. I likewiſe ſowed at the ſame time ſome of this ſprouted ſeed in a bed of my kitchen-garden, where it roſe in four days. I intend alſo to venture ſome of it about the end of next April in a ſpot with beans; and I preſume that as this already ſprouted ſeed will riſe ſooner than them, the plants of madder will be able to bear the firſt weeding and ſtirring neceſſary for the beans; in which caſe the expence of culture will be much leſs than the charge of removing the young plants, and both the hazard and the delay of their taking freſh root will be avoided. If this trial ſucceeds, it will be the greateſt inducement that can be for the farmer to adopt the ſame method, ſince it will require only one ploughman, a woman to ſow the beans after the plough, another to lay the ſprouted madder in the furrow, and a perſon to cover the whole over with a rake.

" The gathering of the ſeed is expenſive when one has but little of it, becauſe, for fear of loſing any of it, it is gathered almoſt ſeed by ſeed. I thought myſelf rich enough this year to try another way of doing this work. I cauſed all the tops to be cut off with a reaping hook, when there remained upon them but a few ſeeds that were not ripe, and the whole was then laid upon cloths in the ſun. In two or three days the ſtalks and leaves became ſo brittle, that a few ſtrokes of a ſwitch reduced them into duſt. Two turns of a winnow blew away their duſt, and with it the unripe ſeeds, which, after they had been dried, were found to be lighter than the black or purple onces, in which the horny ſubſtance was formed. I hope next year to be in a condition to proceed with ſtill leſs precaution, that is to ſay, to mow at once all the branches and ſtems, and then to ſeparate the ſeeds from them in the ſame manner as before. It generally is during the whole of the month of September that the ſeed of madder is fit to be gathered.

" After the ſeed has been thus ſeparated from the ſtalks and winnowed clean, it muſt be expoſed to the ſun till it becomes perfectly dry; for if there remains the leaſt mucouſneſs in the black pulp which ſurrounds it, a fermentation will enſue in the winter, or at leaſt a mouldineſs, which will deſtroy the germ. It muſt afterwards be put up in bags of thin cloth, and theſe ſhould be hung to the cieling of a dry and airy place, as well to preſerve the ſeeds from all moiſture, as from mice, which are very fond of them.

" If it be intended to ſow wheat after the crop of madder, the roots of this laſt muſt be taken up in the beginning of October. It is not poſſible for me yet to point out a better method of doing this, than to begin at one end of the field, and trench the whole ground two or three feet deep, whilſt women gather up the roots as the men purſue their digging. The ground is then ſo well prepared for wheat, without uſing any dung, that two-thirds, or at moſt three-fourths of the uſual quantity of ſeed, will be ſufficient to ſow it.

" The madder now taken up might become burthenſome to the planter, if the conſumer thereof ſhould ſeek to take advantage of the eaſe with which it corrupts: for the huſbandman would in ſuch caſe, be forced either to dry on kilns whatever he takes up in this ſeaſon, or to ſell it at whatever price the buyer ſhould be pleaſed to offer. Theſe inconveniences ſeemed to me the greateſt obſtacles to the progreſs of this branch of cultivation, becauſe they neceſſarily required, in the common way of proceeding, either that kilns ſhould be built for drying the madder, or that its roots ſhould not be dug up till they were to be ſold.

ſold. I therefore tried, as follows, to remove theſe diſadvantages. On the ſixth of October 1761, I dug in my garden, a hole three feet deep, into which I threw thirty plants of madder, then filled up the hole, and let it remain thus expoſed to the air and rain. I cauſed it to be opened on the 30th of laſt March, and found all the roots in good condition. It was filled up again till the 15th of September, when, upon its being opened anew, even the vermicular roots, the broken ones, and thoſe which had been ſeparated from the plant, ſeemed to me as firm and as ſound as when they were firſt put into it; but to be certain whether they had not ſuffered ſome alteration imperceptible to the eye, I have dyed with them in compariſon with roots which I took up on purpoſe, and I have not found any difference in the liquor, or in the brightneſs and fixation of the colour.

"The huſbandman may therefore, in caſe of need, keep his crop of madder a year in a hole made in his farmyard, or in a pit dug at the end of the field; only obſerving to lay it in alternate layers of roots and of earth. He will thus be enabled to wait till he finds a proper opportunity to ſell, and the buyer will no longer have it in his power to tyrannize over him by taking advantage of his neceſſities. The dyer, who will know his own intereſt well enough to adopt my method of dying with freſh roots, may alſo keep them equally well in the ſame manner, in a hole in his cellar, from whence he will take, whenever he pleaſes, whatever quantity of them he has occaſion to uſe.

"It may not be amiſs to repeat here, that when theſe roots are uſed freſh they need only be waſhed a little to clear them of earth, and that the quantity of them put into the dye ſhould be after the rate of four pounds for each pound of ground madder which the operation would require. Theſe roots are cut into middle-ſized pieces, and pounded in mortars of ſtone or wood (iron abſolutely excepted) till they are reduced into a kind of pummice, and this is thrown into the copper when the water (of which I have experienced that, in large works it is hurtful afterwards to increaſe the quantity) is a little more than lukewarm. The liquor is then heated to a degree at which a man can hardly bear to hold his hand in it, and whilſt it is in this ſtate the ſtuff or cotton is puſhed down into it, and there worked about during three quarters of an hour, between hot and boiling, after which the liquor is made to boil during three quarters of an hour more.

"As this liquor remains, after the dying is finiſhed, much finer than that which has been made with the Dutch ground madder, I intend this winter to try whether it may not be put to ſome farther uſes; and I ſhall, in due time, give an account of whatever I may ſucceed in."

M. Duhamel thinks the month of September the moſt proper time for cutting the ſtems of madder, in order to their being made into hay. The Flemings cut theirs in Auguſt: but that is when they do not intend to ſave the ſeed, of which indeed their madder yields but little, as was before obſerved. As Mr. Ray informs us that the madder which grows wild in England preſerves its verdure all the winter, it will become a conſiderable addition to our winter and ſpring ſucculent food for cattle, and this will add greatly to its value; for this plant has been experienced to be an excellent fodder for cattle.

Cows fed with the tops of madder yield plenty of milk, which is a little tinged with red; and the butter of it is yellow and well taſted.

After the madder has been cut for hay, the ground ſhould be gently ſtirred, eſpecially in the alleys, and particularly if theſe are to be planted with madder the next year.

When the ſame ground is to be planted anew with madder, the whole of it ſhould be thoroughly ploughed after all the roots are taken up, and the beds ſhould now be made where the alleys were before. If the ground is ſown with wheat after this ſecond crop of madder has been taken up, the farmer may reaſonably expect an abundant crop of corn: for beſides that madder does not impoveriſh the ground, the weedings and frequent ſtirrings neceſſary for the culture of this plant prepare it well for wheat or any other crop. M. Duhamel confirms this by the following experiments.

A field of madder being dug up, he ſowed it with ſpelt, which was harrowed in, and did not appear for ſix weeks, becauſe the ground was very dry: and even after this, only a ſmall quantity of it ſprouted: yet, at harveſt, this field yielded as many ſheaves as others in the ſame country; but with this eſſential difference, that the ſtraw of theſe was ſix feet long inſtead of four, and the ears were as long again as thoſe in the other fields.

Another year, having ſown ſpring-wheat after a crop of madder, there were, at harveſt, twenty dozen of ſheaves on an arpent (about an acre and one fifth) whilſt the other fields yielded but eight or nine. Likewiſe, another year again, having ſown oats on a piece of ground where the madder has juſt been dug up, it yielded forty dozen of ſheaves to the arpent. The common lands produced that year but five or ſix dozen.

The peaſants about Liſle, being in too great a hurry to enjoy the fruits of their labour, take up their madder before its roots have attained a proper ſize. The Zealanders let their's grow larger. A medium ſhould however be obſerved; for the roots which have remained long in the ground yield leſs dye than thoſe which have ſtood only till they have acquired the bigneſs peculiar to each kind.

This root, which is one of the beſt ingredients that can be uſed for dying wools and ſtuffs, gives them a red colour, not very bright, it is true; but which reſiſts, without alteration, the influence of the air, the heat of the ſun, and the effects of the ingredients made uſe of to try colours: it contributes alſo to make other mixed colours laſting: finally, a method is found out of giving cotton a very pleaſing and laſting carnation colour with it. All parts of the root do not yield this red; the dye of ſome parts fades, other parts are worth nothing at all.

In examining a well-conditioned root of madder with a microſcope, under the outer bark, in the fleſh may be perceived certain red particles, which certainly yield the colour which the root contains; but there is, beſides this, ſeen a great quantity of woody ſubſtance of a fallow colour; and this ſubſtance probably impairs the firſt mentioned colour. According to M. de Tourniere, this fallow colour is not ſo good a ſhade as the red; and he imagines that leys, &c. give a brightneſs to the colours dyed with madder in no other reſpect than by abſtracting this fallow colour. The ſun and dews have the ſame effect on yarn dyed with madder, when it is expoſed on the graſs.

M. de Tourniere alſo imagines, that the part which yields the red, is, in the green root, diſſolved in a mucilaginous juice; for the bark, and the other parts which contain moſt red, are alſo moſt ſucculent: by drying them

in a kiln they loſe ſeven eights of their weight, and yet the roots are not perfectly dry; for they bend before they break; they are rather bruiſed than ground by the mill; and this unctuous powder is apt to clot: it is true, that in time they loſe this unctuouſneſs, and become dry; but at the ſame time the quality of the red particles is lowered. Theſe obſervations are well deſerving of attention; for they make it evident to us, that theſe valuable particles may be impaired by too great a heat: ſuppoſing it unctuous, were it too much dried, perhaps water would not diſſolve and ſeparate its parts. Finally, theſe reflections of M. de Tourniere agree very well with the experiments of M. d'Ambournay, and convince us that madder-roots may be uſed green with very conſiderable advantage. But green madder can never be uſed, except when the grounds lie convenient for the dyers: thus, when madder is to be carried to any conſiderable diſtance, it muſt of courſe be dried, and pulverized. I ſhall reſume this ſubject.

1. As madder-roots are very apt to ferment when they are bought green, it will be neceſſary to examine carefully whether they are ſpotted, or have a muſty ſmell: if the fermentation has given them a black hue, they are by all means to be rejected.

2. The roots to yield a fine dye ſhould be freſh: ſuch as are duſty on being broke muſt therefore be rejected, and with ſtill greater reaſon thoſe that are rotten and worm-eaten: on the contrary, ſuch ought to be preferred as have a ſtrong ſmell ſomewhat like that of liquorice: the ground-madder ſhould be unctuous, and run into clots on being handled.

3. As madder is ſold by weight, it is an advantage to the purchaſer to have the roots quite dry; but he ſhould be careful that they have not been kiln-burnt: ſuch as have a ſtrong ſmell have ſeldom this defect. Too haſty a drying wrinkles and ſplits the bark: and, as it then ſeparates very eaſily from the wood, the moſt uſeful part is loſt: the bark therefore ſhould be ſmooth, entire, and adhering to the wood: but we muſt not confound the true bark with the outer bark, or epidermis, which would only leſſen the brightneſs of the colour.

4. The largeſt roots are not always the beſt: they are frequently yellow, and have but little of that red which alone yields the colour. The very ſmall roots are of little value, as they have too much outer bark, which hurts the colour: but thoſe of the beſt quality are from the ſize of a gooſe-quill to that of the end of the little finger.

5. In breaking the roots there may be ſeen, as I have already obſerved, two ſubſtances differing one from the other: that which inclines to a yellow only, hurts the dye: that of the deep red is the part really uſeful; conſequently the higheſt coloured roots ſhould be preferred.

It would be a uſeful diſcovery could there be a method found out of extracting the red particles without any mixture with the fallow or yellow part: I am of opinion the trials ſhould be made on the green root, that the red particles, which are then in a ſtate of diſſolution, may be more eaſily extracted.

6. As the ſureſt method of knowing the quality of madder is to make a trial of it on ſome piece of ſtuff, it will not be amiſs if ſuch as plant much of it accuſtom themſelves to make this trial, that they may demonſtrate to the purchaſers the quality of their roots: the following proceſs for doing it, is extracted from the works of M. Hellot.

To dye a pound of woollen-yarn, a bath muſt be made with five ounces of allum, and one ounce of red tartar, diſſolved in a ſufficient quantity of water: the wool that is to be dyed muſt be well drenched in this liquor: in about a week half a pound of ground madder root is to be thrown into water as hot as you can bear your hand in; and, after having mixed the water and powder together with a ſtick, the wool is put into it; and the bath muſt be kept hot for an hour, but not boil; for, if it did, the colour would be dull: but towards the end of the time the bath is made to boil; but the yarn muſt be inſtantly taken out.

As very trifling circumſtances will affect the beauty of the colour, it will not be amiſs to make at the ſame time two trials with the ſame yarn; one with the madder that is to be proved, and the other with the fine madder of Zealand, or azala: the beauty of the ſkains will determine which is the beſt madder.

As theſe trials may as well be made on two or four ounces of yarn as a pound, the baths may be made accordingly. I ſhall now treat of the methods of drying and pulverizing madder.

We have obſerved that green roots are very apt to ferment: it is therefore neceſſary to abſtract the great quantity of moiſture that cauſes it. If the weather is very dry and hot, it is certainly adviſable to take the advantage of it to dry the roots in part, and ſave wood; but, if the weather is damp, the roots muſt be ſpread under ſheds, or on barn-floors, and often moved: for, if they were laid in heaps, they would ſoon heat, and change, more or leſs, according to the ſtate of fermentation they were in. With care the fermentation of the roots may be greatly leſſened; and, according to M. d'Ambournay's opinion, they may even be kept good for ſome time; but the roots cannot by theſe means be made dry enough to preſerve them from any change. For ſmall crops a common oven will ſerve; but it muſt not be heated to above forty-five or fifty degrees of M. de Reaumur's thermometer. But this method is very tedious, and it would require very large ovens to ſupply the place of kilns. To ſave the expence of building a kiln, I would recommend the making a place over the roof of the oven, to put the roots in, that they may begin to dry: but, if we grow much madder, it is abſolutely neceſſary to have a kiln proportioned to the quantity that is to be dried, not only of our own crops, but thoſe of the peaſants that cannot afford kilns.

The kilns may be made of very different forms, many of which are of equal goodneſs; but when a man propoſes building one, he ſhould be attentive, 1. That it may contain a large quantity of roots: 2. That it may be worked with eaſe: 3. That as little fuel as poſſible may be uſed: 4. And that it be ſo contrived as to retain an equal and moderate heat. To make theſe matters eaſy to planters, we ſhall deſcribe the kilns that have been long in uſe at Liſle for drying madder-roots: we ſhall point out their defects, as well as the defects of two kilns that were ſucceſſively built at Corbeil; and, laſtly, we ſhall mention the attempts we have made to improve and perfect them.

Deſcription of the Liſle Kiln.

This kiln differs very little from that uſed for drying malt. To have a general idea of it, we muſt ſuppoſe there is a large furnace, in which a great fire is made: this furnace is made under an arch: the hot air and ſmoke paſs through

through a funnel over the furnace, and ſpread themſelves in a ſpace in form of an inverted pyramid, the bottom of which is covered with a perforated floor, on which the madder-roots are ſpread. This is the general form of the kiln; but we ſhall give a deſcription of it according to the figures in the plate, for the uſe of ſuch as intend to build one.

Fig. 1. Plate XVIII. repreſents the ſection of a building, containing a madder-kiln.

In this building may be ſeen a vault, K, K, a ground-floor, L, L, and a firſt floor, G, G, over which we are to ſuppoſe a granery, H. The foundation of the brick-work of the kiln, is ſomewhat lower than the bottom of the vault; the walls terminate in arches, at the bottom of the firſt ſtory; the ſide-walls of the building ſerve as upright ſupporters; and the arches of the kiln are ſuſtained by jams, which are put into the ſide-walls. All this will be better underſtood by explaining the letters of reference.

A, an aſh-hole two feet wide, three feet and a half deep, and two feet three inches high. B, the furnace with an iron grating, *b b*, at bottom. C, a pricked line, which determines the height of the furnace door: this aperture is ſixteen inches wide, and ſeventeen high. D, the chimney, B, the perforated funnel, which diſperſes the heat, by means of the holes, *i i i*. It is to be obſerved, that this chimney is entirely covered at the top, to prevent any thing falling into it. I I I, holes two inches ſquare, by which the heat eſcapes; they are placed chequerwiſe. F, an empty ſpace, into which the heat goes, out of the funnel before it reaches the upper ſtory. G G, a floor ſet with ſquare tiles, on which the roots are to be ſpread one foot and a half thick. Theſe tiles are fifteen inches long, ten or eleven wide, and two thick; they are perforated with conic holes, as here repreſented. H H, tubes four inches wide, by which the ſuperfluous ſmoke eſcapes, and through which fall the duſky particles that drop through the holes in the tiles of the floor G. Theſe tubes are ſtopped by a little iron door, which is opened when the heat is too great.

K, the vault in which the fuel is kept. L places where the undried madder is ſafely kept. M, iron joiſts two inches thick, traverſed by bars which bear the tiles that compoſe the floor. N, iron braces fixed to the beam P, to ſupport the floor G. P, the beam of the ſecond ſtory. Q, a caſement or window, to be opened at the beginning of every drying, to let out the ſmoke. When the madder begins to dry, theſe caſements are ſhut, to keep in the heat. There are alſo in the ſecond flooring two trap-doors, which are open to let out the ſmoke and ſteam.

Fig. 2. repreſents the plan of the furnace. The three iron bars which croſs it, are each two inches and a half broad, and ſix lines thick; they are let into the wall three inches; the bars of the grating are one inch ſquare, and rivetted to the other bars. In this plan are to be ſeen the tubes marked H, to ſhew that they run the whole depth of the furnace. Theſe tubes are very neceſſary to convey into the kiln the heat from the body of the furnace.

Fig. 3. repreſents the plan of the tiled floor, G: it is ſixteen feet ſquare.

As the furnace we have deſcribed reſembles that uſed for drying malt, we were willing to obſerve in what manner it was dried, and remarked, that they lay it about nine inches thick, and that it is very hot at bottom. When M. de Reaumur's thermometer was applied, it roſe upwards of twenty-two degrees above Zero; but the upper part, being influenced by the external air, heats but little: the ſteam that riſes, being condenſed by the cool air, is reduced to water, which occaſions the upper part of the bed of malt to be always wet: for this reaſon it muſt be often turned. In this method, by being often wetted with the ſteam, the bed of malt is much retarded in its drying. We imagined this inconvenience might be removed, by preventing the external air from affecting the ſurface of the bed: and this would be affected by making a covering for it: and, if this covering could be fixed within a foot of the malt, another advantage, which we ſhall mention, would reſult.

It is well known in phyſics, that the vapours which ariſe from heated matter, have a great power of penetrating and heating the matter whence they proceeded, provided they are collected, and in ſome manner reverberated on the matter to be heated: it is on this principle the machine was conſtructed in which the bones of animals could be diſſolved; and we know, that in an equal degree of heat, water has eight hundred times more volatility than air; and vapours or ſteam contain a great deal of water.

This induced us to think, that it would be of great uſe to reverberate the ſteam on malt and madder-roots, by means of the covering above mentioned. M. Villot, a brewer at Paris, who takes all opportunities of improving his beer, has made ſome experiments of this nature, and in part ſucceeded. It is only neceſſary then to contrive a method of putting this in execution in a large building, of which we ſhall in due time take notice.

One great defect of the Liſle kiln is, that the ſmoke, mixing with the roots, charges them with fuliginous matter, which probably hurts the colour, and is perhaps the cauſe of the difference betwixt the Levant madder and that of Liſle, theſe laſt being by no means fit for dyeing cotton, as done in the Levant: beſides, in theſe kilns the workman cannot properly regulate his fire: theſe defects might be removed by making the middle cloſe, and terminating it in a tube of caſt or hammered iron, to carry off the ſmoke: the floor, ſupported by iron bars, might very well be diſpenſed with, and inſtead of it one of wood, lattice, wicker-work, or iron wire, would do; for the funnel once properly ſecured, there will be no danger of fire. In order to enable every one to vary the conſtruction of theſe kilns, we ſhall add ſome reflections and obſervations made with great care by M. de la Levrie, who ſuperintended the building of two kilns at Corbeil.

Remarks on the Kiln uſed at Liſle.

It will not be amiſs to begin by relating the experiments made with two kilns, built one after the other at Corbeil, to dry madder, as thereby the advantages of that, herein after propoſed, will be more evident.

The firſt of theſe kilns was twenty-one feet long, twelve wide, and ten feet high: within-ſide it was ſurrounded by three ſtages of hurdles, like ſhelves, four feet wide, and twenty inches one from the other: the firſt ſtage was five feet from the ground: on theſe ſtages the green madder was laid eight inches thick. In the upper floor was a trap-door, which opened to let out the ſteam of the root. The furnace, which was not without defect, went three feet within the kiln: it was ſupplied with

fuel from without: within-ſide it was furniſhed with metal tubes, which paſſed through the fire: theſe tubes received at one end the outward air, which they diſcharged within, very hot, by an aperture two feet from the ground. The effect produced from this kiln was as follows: the three ſtages, being filled with roots, thoſe on the upper ſtage became dry enough to ſend to the mill. It is true, they dried but ſlowly, becauſe the ſteam, which proceeded, though in no great quantity, from the two lower ſtages, wetted the under part of the hurdles of the firſt ſtage, thereby retarding the work. The heat, which was not powerful enough to raiſe all the moiſture of the madder-root on the lower ſtages in ſteam, made them ſweat abundantly, ſo that the under parts of the hurdles were covered with drops of water as big as the finger's end, which fell from the ſecond ſhelf on the firſt, where they wetted the root; and from the firſt ſhelf they fell to the ground. On the upper ſhelf were very few of theſe drops of water, except for a very ſmall ſpace of time after the kiln had freſh roots put into it, becauſe at the upper part of the kiln the heat was powerful, and regularly diſperſed, whilſt at the bottom it was cold. At each ſtage was fixed one of M. de Reaumur's thermometers: after four days continual fire the loweſt ſcarcely roſe to eighteen degrees; the ſecond, ſomewhat higher; and the uppermoſt never paſſed eighteen degrees, which is thought ſufficient, when the drying is not retarded by any ſteam from below. When the dried root was carried to the mill, the root from the ſecond ſtage, which had loſt part of its moiſture, was removed to the third, and that of the firſt ſtage, ſtill wet, was laid on the ſecond, the firſt ſtage being filled with freſh roots. The loweſt thermometer then fell to fourteen degrees, and the uppermoſt to Zero: this induced them to dry all the roots that were at once put into the kiln, before they admitted any freſh; yet even in this method it was neceſſary to move the roots from the lower to the upper ſtages, where the laſt laying dried faſter than the others. As this work was tedious and troubleſome, it was determined to take down this kiln, and build a new one, now in uſe.

This ſecond kiln is of the ſame length and breadth as the firſt; but the hurdles on which the madder is put are raiſed only ſix feet from the ground, and the apertures of the furnace, which ſupply the hot air, are level with the ground: they, beſides, continued to avail themſelves of the miſtaken advantage of encreaſing the ſurface to contain more roots, by making, as in the firſt, three ſtages of ſhelves. The roots indeed dry in it faſter, becauſe the furnace yields more heat; but this heat is very unequally diſperſed at the different heights, and in the different parts of the length of the kiln; becauſe the ſame inconveniences ſtill ſubſiſt, as they have made in it, like the other, three ſtages, one above the other, and they have formed the kiln long, without letting the furnace extend through its whole length. They have beſides placed the firſt ſtage too near the fire; but this may be remedied by taking it entirely away, and uſing only the uppermoſt ſtage, which is fifteen feet from the bottom of the kiln, and may extend over the whole of it: the heat will then be more regularly diſperſed. The roots may be laid fifteen or eighteen inches thick, and may be much eaſier attended to than on the ſhelves, which occaſion a great deal of trouble: there might alſo be two furnaces, one at each end of the kiln, and the tubes might be carried over the whole length of it.

From what has been ſaid, we may conclude, that to dry a plant like this, which contains a great deal of moiſture, no advantage can reſult from having a kiln with three ſtages, one hurting the other; ſince the heat tending always upwards, the roots muſt be moved higher, which cannot be done without trouble, loſs of time, and expence; whereas, the ſame quantity may be dried in leſs time on a floor raiſed eighteen or twenty feet above the furnace.

It is certain that a peaſant, who raiſes madder after a proper method, will always be a greater gainer than ſuch as are obliged to hire day-labourers. But the peaſent cannot go to the expence either of a kiln, or a mill: it muſt be planters who raiſe large quantities of it, and can afford the expence, that have them: thus it is to be preſumed, the peaſants will be under a neceſſity either of ſelling their roots green to the dyers, of taking them up in the ſpring to dry them in the ſun, of drying them in their ovens, when they have only a ſmall quantity; or, finally, of carrying their roots to the kiln, as they do their grapes to the preſs.

The Liſle kiln, though built on a good principle, is too expenſive for a young planter. There muſt be ſtrong walls to ſupport the arches, internal abutments, and bricks to build the arches with. In ſome provinces there is not a workman capable of turning an arch in brick-work. The floor requires many large iron-bars. On the other hand, a kiln in the form of an oblong ſquare, like that at Corbeil, will never heat equally in its whole extent, unleſs tubes be made to convey the ſmoke through various parts of the kiln, before it reaches the chimney, or there is a furnace at each end. All this is expenſive, and ſubject to inconveniencies.

Perhaps then a kiln ſomewhat reſembling a malt-kiln would do; and this might any where be built at a ſmall expence: ſuch a kiln need not be above eighteen feet ſquare, and eighteen or twenty feet high from the ground to the floor. Underneath the floor ſhould be a reverſed pyramid, ſomewhat obtuſe at bottom, to receive the funnel and tubes that are to give the ſupply of hot air: this may be made with quarter-ſtuff covered with lath and plaiſter. This kiln does not require any large furnace. The new kiln at Corbeil is much larger, taken from the ſecond ſtage to the bottom; yet has the heat been brought there to upwards of forty-five degrees. The floor of the kiln is to be made with joiſts eight inches by four, covered with laths, grating, or with hurdles as at Corbeil, where it has already laſted ſeven or eight years: there muſt be walls to ſupport the roof and beams, and it ſhould have two windows: there ſhould be a plaiſter-floor eight or nine feet above the grating, with one or more trap-doors, as they let out the ſteam much better than the windows: laſtly, the beams ſhould be plaiſtered. There is reaſon to think that ſuch a kiln would coſt little, and anſwer the intended purpoſe. It ſhould have been obſerved, that over the grated floor ſhould be laid a large thin cloth, or rather a hair-cloth, riſing round the edges, and faſtened with nails: this is particularly uſeful when ſmall roots are dried, as it prevents their falling through. A foot above the roots may be put wooden traverſes, over which may be laid ſtraw-mats quilted on cloth: this will keep down the ſteam, and may be of great ſervice, as has been already obſerved.

The

The Furnace of this Kiln.

The furnaces of the Liſle and Zealand kilns are certainly neither of them proper for drying madder, any more than thoſe of the malt-kilns: they have all the ſame defect, as they fill the kiln with ſmoke, which damages the roots. It was this inconvenience induced us to endeavour to contrive one that would give a great deal of heat, without the above defect. This may be probably effected, by not letting the funnel be perforated, and carrying tubes from it which ſhould run under the madder before the ſmoke was diſcharged; and by having other tubes run near the fire, to circulate in the kiln a warm air, which they ſhould receive from without. We have made the trial of ſuch a furnace, and confeſs it did not yield ſufficient heat: the furnace ſhould certainly have been made larger, but the expence is a continual objection, which, beſides being conſiderable, is pure loſs to one that makes experiments for the public good, without being in a ſituation of reaping any profit from them. We ſhall cloſe then what we have to ſay on madder-kilns, by concluding, that malt-kilns ſeem well adapted to the purpoſe; but ſome method muſt be found to prevent the ſmoke damaging the roots.

Madder well dried and cleaned may be ſold in that ſtate to the dyers; but if it is to be pulverized, there will be occaſion for a mill, which we ſhall now deſcribe.

Deſcription of a Mill, at Liſle *in* Flanders, *for pulveriſing Madder.*

Plate XIX. Fig. 1. repreſents the part of a madder mill: it is inſulated, and covered only by a ſlight thatch. The figures 2, 3, 4, 5, and 6, are ſupplementary to the firſt: we muſt have recourſe to them in our explanation of the parts of the mill: they are therefore diſtinguiſhed by the ſame letters, and each piece is repreſented apart.

A is a lever, or pole, nine feet eight inches long, and ſix inches by four in magnitude. B, the axis of the wheel, ſix feet four inches ſix lines high, and nine or ten inches diameter. C, ſtays, or knees, four feet ſix inches long, and four or five inches ſquare. D, the cogged wheel, three feet one inch ſix lines ſemi-diameter, and furniſhed with fifty-ſeven cogs.

The fellies, or circumference of this wheel, muſt be eight inches by four large: they are ſecured by an iron hoop. The traverſes are ſix inches by four thick, pinned and keyed. The cogs are made of apple-tree wood, and project three inches three lines: they are two inches and a half by two, at their inſertion, and two inches and a half by one at top: and beneath the wheel they are two inches long, and one and a half ſquare: they act on the rounds of the trundle-head about one inch and a half of their length. The pins that faſten them are alſo apple-tree wood.

E is a beam twelve inches ſquare. F, the trundle head, thirteen inches ſemi-diameter, furniſhed with eighteen rounds, each a foot long, and two inches diameter: the ends of this trundle-head are two inches and a half thick, and hooped with iron. There are alſo two iron bars pinned on to ſecure the joints of the wood.

G is another axle-tree, or turning-beam, eighteen feet ſix inches ſix lines long, ten inches ſquare near the trundle-head, and fourteen inches diameter in its octogonal part. H, lifters four inches nine lines long, five inches broad, two inches and a half thick. Hence it is apparent, that there are fifteen lifters inſerted into the axle-tree, to ſerve five beetles; that is, three to each. For this reaſon the lifters, the catches, and the peſtles, are diſtinguiſhed by the ſame figure.

K, flyers four feet five inches long, and four inches ſquare: they are loaded with lead at their ends. L, catches, which anſwer to the lifters, H: they project five inches nine lines, and are five inches broad and two and a half thick.

M, other catches inſerted into the ſides, or thickneſs of the beetles, N, and anſwer to the levers. Q, N, beetles ten feet four inches long, and four inches ſquare. They are round at the ends next the mortars, and ſhod with an iron foot four inches diameter, which may be ſeen in figure 6. The beetles are numbered in this manner, 1, 4, 2, 5, 3, (Fig. 1.) to ſhew the order in which they play when the machine is in motion. O, croſs-bars ſix inches by four, which ſupport the joints, P.

P, joints eight inches long, ſix wide and four thick. An iron pin, keyed, paſſes through each joint, and ſupports a moveable lever, Q, which acts on the catch, M. when the peſtle, N, is to be kept up. Q, levers, two feet three inches ſix lines long, three inches thick, by four wide.

R, keeps, ſix or eight inches wide to prevent the beetles from being diſordered. S, an upright poſt four inches ſquare, in which the croſs-bars and keeps are inſerted. T, mortars cut in a ſingle piece of wood ſixteen inches ſquare: they are eleven inches deep, and their greateſt diameter is ſeven inches: the bottom is lined with lead three or four lines thick.

V, a trough to prevent waſte, over which hangs a cloth, faſtened above to the keep, whilſt the mill is at work.

X, a beam twelve inches ſquare; this beam, and that at the other end, marked E, reſt on the timber work that ſupports the roof. The ſockets and pivots may be ſo well comprehended by the plate, that letters of reference were thought unneceſſary; the ſockets are braſs, the pivots ſteel.

We have purpoſely omitted giving the dimenſions of every part, to avoid confuſion; but the machine may be eaſily conſtructed by attending to the diſcription we have given, which is very exact.

But though the mill deſcribed above, is now actually employed in grinding or pulverizing madder at Liſle; yet it labours under ſeveral imperfections, which we ſhall endeavour to point out, and deſcribe a mill conſtructed in a more perfect manner.

There will be, however, no occaſion to deſcribe the wheel work of this mill, it being the ſame as that of Liſle: it will be ſufficient to give the proportion of the parts which compoſe it. The pole, or lever, from the center of the axis of the cogged wheel, to the part where the links of the ſpring-tree bar are faſtened, is nine feet long; the wheel is five feet ſemi-diameter, and has ſeventy-two cogs; the trundle-head is ten inches ſemi-diameter to the center of the rounds, and has twelve rounds; thus it makes ſix turns to one of the wheel. The horſe, going three feet in a ſecond, makes three rounds and a half in a minute, and the trundle-head twenty. The axle-tree having on its circumference three lifters to every beetle, each beetle makes ſix ſtrokes in a minute,

minute, and the four two hundred and forty in the ſame ſpace. The ſquare part of the axle-tree, on which the trundle-head is fixed, is made out of a piece of wood five inches ſemi-diameter; the other part of the axle-tree is larger, being ſeven inches ſemi-diameter. It is neceſſary it ſhould be ſo large, that the tenons of the lifters may have a proper length and thickneſs: it is much better to be round than an octagon, or any other faced form, as the mortiſes may be more regularly made. From the end of the lifters to the center of the axle-tree is twelve inches; ſo that in their motion they form a circle two feet diameter: the upper face of theſe lifters is cut in a curve, the radii of which are tangents to the circumference of the above-mentioned circle; the largeſt of theſe tangents is twelve inches, and determines the greateſt riſe of the beetles. By the lifters being thus curved, the reſiſtance is equal, at whatever height the beetles may be, as they are always in contact with the lifters at the ſame diſtance from their center of gravity. As there are on the length of the axle-tree twelve lifters in four parts, they form, one with the other, angles of thirty degrees, ſuppoſing them to be ſeen one behind the other, as if inſerted on the ſame plane: on this account, when the firſt beetle is raiſed to half its height, the ſecond is about to riſe; the firſt quitting the lifter, the third is on the point of riſing, &c. We ſay, on the point, becauſe we are to obſerve, that the lifters go under the catches, or under that which ſupplies their place, five or ſix lines; and that the greateſt tangent of the curve, being twelve inches, is leſs, by near ſeven lines, than the ſixth part of the circumference of the circle, and gives the firſt beetle time to quit the lifter before the third riſes: this is neceſſary, that the power may never have more than two beetles to act upon.

The front of the frame-work is that ſide before which the axle-tree turns. The frame-work conſiſts of two beams, ten feet long, and eight inches ſquare: betwixt them, at each end, is a traverſe quarter, ſix inches by four. In the middle of the length and width of the beams, riſe two uprights, which are mortiſed and pinned: they are twelve feet eight inches high without their tenons, fourteen inches wide, and ſix inches thick, ſupported by a brace mortiſed into the front at the height of two feet, at the back part four feet and a half. Betwixt theſe two uprights is the block on which the beetles fall: it is made of a piece of dry tough elm, four feet and a half long betwixt the uprights, to which it is joined by a dove-tail two inches thick, and as much deep: it is twenty inches high, and eighteen broad: it reſts the whole breadth of its ends on the edge of the beams, and betwixt them, on three pieces of wood, at equal diſtances, that lie on the brick-work, which ſupports the whole. The block is divided croſs-ways, by a partition two inches thick, parallel with the uprights, and of the ſame breadth, fixed into the block by two tenons, and in a groove wide enough to receive its whole thickneſs; the ſame is obſerved in the back part of the firſt keep, which is fixed: the upper end is, in like manner, fixed to the upper-keep: this partition divides the block croſs-ways into two troughs, each twenty inches long, formed by two ſloping planks; ſo that the troughs are four inches and a half wide at the bottom within, eleven inches and a half at the top, and twelve inches perpendicularly high: and to prevent the loſs of the light duſt that riſes in the work, the ſpace betwixt the edge of the troughs, and the firſt keep, is boarded up; the boards at the back-part, as well as the ſides of the troughs there, are faſtened with grooves and dove-tails into the uprights and partition; thoſe before lift up in a groove like a ſaſh, and are faſtened by turn-buckles; the fronts of the troughs take entirely off; the pulverized root is taken out with a wooden ſpoon, and a feather broom, and they let it fall on a ſhelf before, which has a ledge four inches high: the fronts of the troughs are then put on again, and are filled with branch-madder; the ſliding-ſhutters are pulled down, and the peſtles are ſet at liberty to work, which had before been ſtopped whilſt the troughs were emptied; this takes but little time in doing, and the mill continues going during the time they gather up the root, and bolt or ſifts it. There are two keeps, which ſerve to direct the beetles: the under part of the firſt is three feet, and the under part of the ſecond ten feet: above the block they are three inches and a half thick; the firſt is made level in the front with the back of the groove, that the ſliding ſhutters may reſt on it when they are raiſed. Each keep conſiſts of two parts; thoſe at the back are let into the uprights, and pinned to them, and ſtrongly faſtened to the partition: thoſe in the front are made to take down, and put up, as occaſion ſerves; they ſlide in the grooves of the uprights, and thoſe that run along the middle of the partition: they have, beſides, two pins, by which they are kept in their places.

The beetles are, at the lower parts, twelve inches wide, eighteen inches high, and four inches thick; ſo that their face, or bottom, contains forty-eight ſquare inches: the upper part, or ſtock of each peſtle, is eight feet and a half long, four inches wide, and three thick; ſo that in the whole, they are ten feet long, without compriſing the cutters, which are four inches long, and formed like a carpenter's chiſſel; the blades of them are two inches and a half wide, and the tongues three inches and a half long: there are ſeventeen to each beetle. There are no catches, becauſe the lifters being in contact with their extremity, always at the ſame diſtance, five inches from the center of gravity of the beetles, the reſiſtance occaſioned by the friction of the ſtocks in the keeps, would have been very conſiderable. To avoid this inconvenience, a mortiſe twenty-five inches long, and three inches wide, is made in the face of the ſtocks of the peſtles, ſtrengthened on the ſides by cheeks two inches thick. The upper parts of theſe mortiſes are ſix feet above the block; that is, on a level with the center of the axle-tree: this part is lined with a plate of copper, ſtrongly ſcrewed, well poliſhed, and rounded at the edge, to facilitate the fall of the beetles. On the ſide of the beetle-ſtock, ſixteen inches below the upper keep, are fixed catches a full inch thick, two inches high, and projecting four inches, to keep the beetles up while the troughs are emptying.

The levers, which ſerve for this purpoſe, are placed behind, and reſt on ſhoulders fixed on a piece of wood, which bears by its two ends on two brackets, mortiſed and pinned into the two uprights, and ſupported by braces: theſe pieces are ſix inches ſquare. The levers are made of quarter-ſtuff, ſix inches and a half ſquare, as well as the lifters of the axle-tree. The upper face of the ſhorteſt arm of the lever is rounded like the lifters, in a curve deſcribed by the original circle, the radius of which is the ſpace from the middle of the catch to the center of motion of the lever, which ſhould be parallel to the bottom of the catch. The radius of this circle, as well as the greateſt

greateſt of the curve, ſhould be fifteen inches, that the beetle, being raiſed thirteen or fourteen inches, may not ſlip off. That the levers may be the ſtronger, the wood muſt not be croſs-grained; and in the center of motion, it ſhould be traverſed by a ſquare iron bar, projecting two inches on each ſide: theſe projections, being rounded into pivots, reſt on the ſhoulders in braſs ſockets. A cord is faſtened to the ſhorteſt arm, and the end of it is faſtened occaſionally to wooden pins at the back of the block, to keep the levers ſomewhat lower than the catches, whilſt the beetles are at work. The longeſt arm leſſens by degrees towards the end, till it is reduced to a ſquare: at this part is fixed another cord, which is faſtened to the ſame wooden pins, when the beetles are to be kept up. The above deſcription, with figures on the copper-plate, will be ſufficient for an ingenious mechanic to conſtruct a mill of this kind, which will doubtleſs be of great advantage to this kingdom, as conſiderable quantities of madder are now planted, and ſome of it fit for uſe.

REMARKS.

The beetles of this mill weigh only one hundred pounds with their mounting; perhaps a few pounds more, which may be abſtracted by taking off a few inches of the lower part: there are never more than two beetles raiſed at a time, and one hundred and thirty-three pounds and a half for the power to act upon. A middle-ſized horſe is generally reckoned able to apply one hundred and eighty pounds of his ſtrength to move a machine, working for four hours together, and going three thouſand ſix hundred yards in an hour: he often goes faſter, but ſo was this mill calculated: there remains then forty-ſix pounds and two-thirds for the action, which is more than it amounts to in this machine: we may even venture to aſſert, that the friction of it is leſs than any other mill of the kind. A horſe may bear this work the better, as every five or ſix minutes there are two or three minutes reſpite to empty the troughs, and give them a freſh ſupply. This mill at Corbeil never pulverized above two hundred pounds of roots a day, becauſe that was all the kiln could ſupply it with; but the time in which this work was done, induces us to think it could eaſily pulverize four hundred and eighty, or five hundred pounds. They ſay that the Liſle mill can pulverize five hundred pounds in twenty hours: we ſcarcely believe it, eſpecially as we imagine it does not work in the night: thus we muſt ſuppoſe it really works only ten hours, like that at Corbeil. Be it as it may, the work of theſe mills ſhould be calculated by the weight of their beetles, the number of blows they ſtrike in a minute, and the ſuperficies of their baſes; that is, the Corbeil mill is to that of Liſle, as four hundred pounds, the weight of the four beetles multiplied by two hundred and forty, the number of blows they ſtrike in a minute, and the product by one hundred and ninety-two, the ſuperficies of the baſes of the four beetles, is to three hundred and eighty-five, the weight of the five beetles, multiplied by one hundred forty-two and a half, the number of blows they ſtrike in a minute, and the product by ſixty-three, the ſuperficies of the baſes of the five beetles; or, after the numbers are reduced, as ſixteen is to three; by which it appears, that if the Corbeil mill pulverizes five hundred pounds in twelve hours, that of Liſle ſhould pulverize no more than one hundred.

The indifference they diſcover in Flanders, with reſpect to the ſituation of the kilns and mills, is worthy of blame: they are, it is ſaid, in ſeparate buildings, which have no communication: nothing can be more inconvenient. It is well known at Corbeil, that the root, which they ſome time ago pulverized in a little hand-mill, fixed in a barn, ten or eleven yards from the kiln, which had no influence to warm it, grew damp, and clogged under the cutters, by which it was much damaged. This work is always done in winter, and it is ſcarcely poſſible it ſhould be otherwiſe: the fogs muſt therefore be guarded againſt.

The kiln we have recommended would contain four thouſand pounds weight of green madder, which would yield five hundred pounds of dry root when it had been there forty-eight hours: the mill can pulverize this quantity in a day. If one had a very conſiderable crop, for inſtance, four hundred thouſand pounds, which would yield fifty thouſand pounds of dry root, and this is as much as the mill could turn out in four winter months, working every day, it would be neceſſary to have two kilns. The buildings to contain the kilns and mill might be diſpoſed nearly in the following manner. A building ſhould be erected ſixty-three feet long, and twenty-one wide, with a floor twenty or twenty-two feet from the ground, which ſhould be a ſtore-room for part of the green root: the under part ſhould be occupied by the mill and its frame-work, ſo that at each end there would be a ſpace of eighteen feet to the walls at the extremities: in the middle of this ſpace the apertures of the furnaces to heat the ſtoves ſhould be made, which ſhould be ſo ſituated, that the floors of the kilns ſhould be on a level with that of the ſtore-room: trap-doors might be contrived in the floor of the ſtore-room, to throw the dried roots down; and as they ought to be kept dry till they go to the mill, they may be heaped round the furnace under the reverſed pyramids of kilns; for they ſhould be kept dry till they are barrelled up.

On a ſuppoſition that the produce of four hundred thouſand pounds might be pulverized in the four winter months, ſome place ſhould be provided to keep it in proper order till the laſt went to the kiln: it muſt be ſpread at moſt two feet thick, that it may every day be turned. Experience convinces us, that eight cubic feet of green root weigh one hundred pounds. The ſurface of the granary will give one thouſand three hundred and twenty-three ſquare feet, which, divided by four, give three hundred and thirty quintals and a quarter, or thirty-three thouſand ſeventy-five pounds; but this does not come near four hundred thouſand pounds. It is preſumed, the beſt way would be to erect ſome large building, four or five ſtories high, which might altogether contain, at leaſt, twelve times as much as the ſtore-room above-mentioned; but this expence might be ſaved, if the root could be taken up in ſmall quantities during the autumn, winter, and part of the ſpring.

Explanation of the Figures of the Corbeil *Mill.*

Fig. 4. Plate XVIII. is the frame-work of the mill ſeen in the front: Fig. 3 is the ſame frame-work ſeen end-wiſe, the upright and beam being taken off.

A, beams, eight inches ſquare, ſeen end-wiſe (Fig. 4.) and the length of one of them, which is ten feet (Fig. 5.)

B, traverſe quarters, which are fixed into the beams; the length of one of them is ſeen (Fig. 4.) and the ends of

of both are ſeen (Fig. 5.) they are ſix inches by four.

C, a flooring or ſtage, laid on the grooved edge of the beams and the traverſe quarter.

D, uprights, fixed to the beams: their thickneſs may be ſeen (Fig. 4.) the top of one of the uprights only is perceivable (Fig. 5.) over the upper keep, N; and the breadth of the bottom is diſtinguiſhed by two pricked lines on the end of the block which covers it, as the remainder of it is concealed by the middle partition. Theſe uprights are twelve feet eight inches high, ſix inches thick, fourteen inches broad, as high as the axle-tree, then reduced to ten inches.

E, braces which keep the uprights ſteady on the beams; thoſe in the front are mortiſed at the height of two feet, thoſe behind at four and a half: they are ſix inches by four.

F, the block, on which the beetles fall: it is made of elm, four feet and a half long betwixt the uprights, and twenty inches high by eighteen broad: it has at each end a dove-tail two inches thick, and as much deep, which goes into the grooves of the uprights.

G, a ſhelf, level with the upper part of the block, of the ſame length, twelve inches wide, two inches thick, and a ledge four inches high: it reſts on a groove at the edge of the block, and on the brackets H, Fig. 4 and 5.

I, three pieces of wood, which ſupport the block.

K, the brick-work, which is the foundation of the frame-work.

L, a partition which divides the block into two parts: it reaches from the block to the upper keep; it is two inches thick, and the ſame breadth and ſhape as the uprights: it has on the front, and two ſides next the uprights, grooves which run up till it begins to narrow; there are other ſimilar grooves in the uprights. This partition conſiſts of two parts: the lower part is fixed in a groove of the block, and above with a tenon, and is beſides pinned to the back part of the firſt keep, which is fixed: the upper part is tenoned into the upper part of the firſt keep, and the under part of the ſecond: they go into grooves that croſs the whole breadth of the front parts of the keeps, which are moveable.

M, troughs in which the roots are kept: they are four inches and a half wide at bottom, eleven inches and a half at top, and twelve inches perpendicularly: they conſiſt of two boards ſloping before and behind (Fig. 5.) the ſpace between their edges and the firſt keep is boarded up. In the front *d*, are ſliding ſhutters. The front of the troughs take off. In Fig. 4. is ſeen one of the troughs open, and the ſliding ſhutter puſhed up: two of the beetles are alſo viſible, one quite, the other half raiſed.

N, are keeps, three inches and a half: their breadth conſiſts of two parts: thoſe behind are entirely fixed to the uprights: they are ſeven inches broad, notched half the thickneſs of the ſtocks of the beetles, in the parts where they paſs: the other two pieces take off at pleaſure, and are notched in the ſame manner to give the beetles room to work: they have each of them two keys, or tongues, four inches broad, four long, and one thick, which go into mortiſes in the fixed part of the keep, between the ſtocks of the two beetles belonging to each trough, where they are faſtened by two large pins, *g*. They ſlide on the grooves of the uprights: the undermoſt is ſix inches broad, that the ſhutters may ſlide over it: the uppermoſt is four inches, conſequently projects an inch: the edges are rounded off. The under part of the firſt keep is three feet above the block; the under part of the ſecond, ten feet.

O, beetles, ten feet high: they are twelves inches broad at bottom, to the height of eighteen inches (Fig. 4.) four inches thick (Fig. 5.) with a ſtock eight inches and a half long, and four inches broad, by three thick. At an inch above the firſt keep, they are left ſeven inches broad, for thirty-ſeven or forty-eight inches, to make room for a large mortiſe, *h*, twenty-four inches long, and three inches wide. The upper part of the mortiſe is lined witn copper, the angle being rounded off. Sixteen inches below the ſecond keep, there are, on the ſides of the ſtocks catches, *i*, two inches high, an inch thick, and projecting four inches. The bottoms of the beetles are ſecured with an iron band, *m*, one inch and a half broad, and four lines thick, and armed with ſeventeen cutters, *n*. The order in which they are placed may be ſeen in Fig. 7. and the ſhape of them in Fig. 8.

P. (Fig. 4.) is a bracket ſix inches ſquare, with its baace, both mortiſed and pinned into the upright (Fig. 5.) There is another on the other upright, not viſible in Fig. 4.

Q, (Fig. 4.) a piece ſix inches ſquare, fixed to the brackets. The end of it might have been ſeen in Fig. 5. but it was not pointed out, to avoid confuſion.

R, ſhoulders, reſting on, and pinned to the piece Q, notched at *o*, to receive the leaves, Fig. 4. alſo at *p*, Fig. 5. to receive their pivots.

S, levers which ſerve to raiſe the beetles, and keep them up while the troughs are emptied: they reſt on ſhoulders, R, where they play: they are made of a piece of even grained wood ſix inches broad, and two inches and a half thick: the length of the ſhorteſt arm is fifteen inches; that of the longeſt ſixty inches. The center of the point ſhould be on a level with the under part of the catches. At the extremity of the long arm is faſtened a cord, *g*, which is fixed to the pins, *r*, in the block, when the beetles are raiſed thirteen or fourteen inches. Another cord, *s*, is faſtened as near as poſſible to the end of the ſhort arm, which is tied to the ſame pins *r*, when the beetles are at work.

T, the turning axle-tree, ſeen endways, Fig. 5. and in front, Fig. 6. It is round, and fourteen inches diameter. It is furniſhed with twelve lifters, on four planes, ſo diſpoſed, that, when it is at work, the lifters anſwer the mortiſes, *h*, Fig. 4. by which they raiſe the beetles, without touching the ſides: they may all be ſeen in Fig. 5. Thoſe that are on the ſame plane, are diſtinguiſhed by the ſame figures, 1, 2, 3, 4, as well as here in Fig. 6. They are made out of pieces of wood, ſix inches broad, and two inches and a half thick: their tenons, X, Fig. 5. are two inches and a half by two, and as long as poſſible, without touching in the center of the axle-tree. From the center of the axle-tree, to the point of contact of the levers with the mortiſes, *h*, is twelve inches: this point is five or ſix inches under the mortiſes. Great care muſt be taken, that the tenons of the lifters be not made of croſs-grained wood.

V, V, (Fig. 7.) the baſe of a beetle, to explain the manner of placing the cutters, which are repreſented by black lines, as if only their edges were ſeen. The pricked lines make the diviſion of the ſuperficies to arrange them.

Y, (Fig. 8.) one of the cutters, marked *n*, Fig. 4, and 5. The height from the upper part of the ſhoulder to

to the edge, is four inches; the tongue three inches and a half; its largeſt part half an inch ſquare; the ſhoulder about eighteen lines diameter: the edges twenty-ſeven lines broad; they ſhould be ſteeled and ſhort.

The Fig. 7. and 8. are drawn by a ſcale, four times as large as the reſt, that their parts might be the better diſtinguiſhed.

MADS, earth-worms.

MAIZE, a ſpecies of grain ſo generally uſed for food in America, that it has obtained the name of Indian corn.

The ſize of its ear differs greatly, according to the fertility of the ſoil, and the warmth of the climate in which it is cultivated; but, at a medium, it is about a ſpan long, and commonly has eight or more rows of grain, each of which uſually contains upwards of thirty ſeeds, of various colours, as red, white, yellow, blue, olive, greeniſh, blackiſh, ſpeckled, ſtriped, &c. ſometimes in the ſame field, and the ſame ear: but the white and yellow are the moſt common: nor does this diverſity of colours ever reach beyond the outſide of the grain, the flour of which is always white, with a little tinge of yellow. Theſe ſeeds, which are as big as large peas, are round at their outer ſurface, very ſmooth, and ſet extremely cloſe, in ſtraight lines. The ear is cloathed and armed with ſeveral ſtrong thick huſks, which defend it not only from unſeaſonable rains, and the cold of the night; for it does not ripen fully in ſome places, till towards the latter end of September, but alſo from crows and other birds, which being allured by the ſweetneſs of the grain before it hardens, flock to it in great numbers, ſuck through the top of the outer covering, and devour as far as they can reach. In the northern colonies, the ſtalk of this plant, which contains a remarkably ſweet pith, and is jointed like a cane, does not grow near ſo high as in the ſouthern parts. It has long leaves, almoſt like flags, at every joint, and at the top a bunch of flowers, of various colours, highly pleaſing to the eye. The northern Indians, far up in the country, have a ſpecies of this grain, called Mohawk's corn, which never grows high, and, though planted in June, ripens in due ſeaſon. The general time of planting it, is between the middle of March and the beginning of June, or, more particularly, from the middle of April to the middle of May.

Mr. Ray was of opinion, that there are only two really diſtinct ſpecies of this plant; but Mr. Miller is certain there are three, which do not alter by culture, and he enumerates them in the following manner:

"The firſt of theſe, with yellow grains, grows naturally in the iſlands of the Weſt-Indies, and has a very large ſtrong ſtalk, which riſes to the height of ten or twelve feet. Its leaves have a broad white mid-rib, are long, broad, and hang downward. The male flowers (for maize has both male and female flowers, ſituated at remote diſtances on the ſame plants) come out in branching ſpikes at the upper part of the ſtalks, and are from eight to ten inches long. The female flowers come out from the bottom of the leaves on the ſide of the ſtalk, and are diſpoſed in a cloſe, long, thick ſpike, which is covered cloſely with their leaves: out of the end of this cover hangs a thin long bunch of filaments or threads, which are ſuppoſed to convey the *farina fæcundans* of the male flowers to the germ of the female. When the ſeeds of this ſort are ripe, the ſpikes or ears are nine or ten inches long, and ſometimes a foot: but theſe rarely ripen in England.

"The ſecond ſort, which has white grains, is cultivated in Italy, Spain, and Portugal. The ſtalks of this ſpecies are ſlenderer than thoſe of the former, and ſeldom riſe more than ſix or ſeven feet high. Its leaves are likewiſe narrower, are hollowed like the keel of a boat, and their tops hang downward. The ſpikes of the male flowers of this are ſhorter than thoſe of the former ſort, and the ears, or ſpikes of grain are ſlenderer, and not more than ſix or ſeven inches long. The grains of this ſort do not come to maturity in England, unleſs the ſeaſon proves very warm, and they are planted early in a warm ſoil and ſituation.

"The third ſpecies, which has a yellow and white ſpike, is cultivated in the northern parts of America, and alſo in Germany. The ſtalks of this are ſlender, and ſeldom riſe more than four feet high. Its leaves are ſhorter and narrower than thoſe of the two former, are hollowed like the keel of a boat, and their tops hang down. The ſpikes of the male flowers of this ſort are ſhorter than thoſe of the others, and the ears, or ſpikes of grain, are ſeldom more than four or five inches long. This ſort ripens perfectly well in England, in as little time as barley, and therefore may be cultivated here to advantage."

This plant is ſeldom cultivated in England for uſe, tho' it might probably turn to good account, as was lately experienced by a gentleman in Lincolnſhire, who planted this corn in an open field, where it ripened perfectly, and yielded an abundant crop; but very great quantities of it are raiſed in Aſia and Africa, in ſeveral parts of France, in Italy, Germany, and North America; its culture in the latter is given in the following manner, by a very worthy and ingenious gentleman of that country, who ſpeaks from his own knowledge.

"The Engliſh in North America plough the ground thoroughly before the grain is planted. They ſeldom, if ever, dung the whole face of the field, but ſometimes put a little dung in each hill of corn, if they think the ground requires it. Where fiſh are plenty, in the planting ſeaſon, they put two or three ſmall fiſh into each hill, with the grain.

"In order to plant the corn, they make trenches, or furrows, with a plough, acroſs the field, at certain diſtances from each other, and croſs theſe with others of the ſame diſtance, which divide the field into ſquares; and where the trenches interſect, the grain is put in and covered. Three or four grains are commonly planted for each hill. The intermediate ground is afterwards ploughed at leiſure, as the plants grow, and want more looſe earth for the roots to ſpread in. The hills are made at the time of weeding; ſome looſe earth being then hoed up over the roots, and round the ſtems or ſtalks of the corn.

"The corn is planted at different diſtances in different places. In the northern colonies, the Indian corn grows low; ſeldom exceeding four or five feet in height; and the leaves being proportionably ſmall, the plants do not require ſo much ground as in the ſouthern colonies, where they frequently riſe to fourteen or fifteen feet. The ſpace generally allowed for the loweſt plants, is three feet, and for the higheſt five or ſix. This diſtance may be more neceſſary in our manner of cultivating this corn; more ground being required to nouriſh three or four plants than one; for I do not know that we ever pluck up any of the plants. An advantage attending this method is, that the labour is leſs in hilling; three or four plants being earthed up in the ſame time as one; and there is more room for paſſing between the rows when the corn is to be weeded.

"At the ſame time that the corn is weeded, the ground is looſened round the plants, with a hoe, and the hills are raiſed and enlarged from time to time, by adding more earth. The morning, before the dew is off, and the evening, are reckoned better for this work, than the middle of the day.

"The hilling of the corn, as it grows, has been the univerſal practice: the deſign being to give the plant more nouriſhment, and to ſupport it better againſt the winds: but of late, ſome planters have thought it better to plant in holes: the reaſon is, that this plant requires a good deal of moiſture; and indeed nature, by the form and poſition of the leaf, appears to have intended the receiving of the rain that falls around, and conducting it to the ſtalk, and by that down to the roots: but a hill round the ſtalk, tends to throw the water off to a greater diſtance: and as to ſupporting the plants, they ſay the hills do not effect it, becauſe, by covering the ſtalks in that part from the air and ſun, which would harden and ſtrengthen them, the mould around them keeps them ſoft and tender, and thereby rather weakens them.

"The panicles, or toſſils, contain the *farina fæcundans* of the plant, and therefore ſhould not be cut off till the grain in the ear is filled. If the toſſils of a whole field ſhould be cut off before that time, there would be no grain at all in the ears. This has been proved by experiment.

"In the more ſouthern colonies, where hay is ſcarce, and the leaves of this corn are very large, they cut them off for fodder: but in the northern colonies, where there is plenty of hay, and the leaves of the corn are ſmall, they generally neglect cutting off the toſſils, and ſtripping off the leaves. They are left on the ſtalks, and the cattle, being turned into the fields, after the corn is gathered in, eat what they like of them: but they are not eſteemed ſo good as what has been cut in ſeaſon.

"An eaſy way of taking the grain out of the ears is, to rub one againſt another, holding one in each hand.

"When the ears are ſtript of their huſks, they are reckoned in the beſt ſtate for preſervation; much better than when the grain is rubbed off from the ear: for then, they ſay, inſects can get at the ſoft part of the grain, and eat into it, which they cannot do while the ſoft part is connected with the cob in the ear, and the hard flinty part of every grain turned outward, and the grains cloſe to each other.

"To preſerve this corn, they make in North America a ſort of bins, or cages, which they call corn-cribs, 15 or 16 feet long, and five or ſix wide, widening upwards to the top a foot or more. They are made of ſapling poles, three or four inches diameter, framed roughly together, by notching the ends where they croſs the corners, at ſuch a diſtance from each other, as but juſt to keep the ears from falling through, that there may be a free paſſage for the air. Theſe bins ſtand abroad, and have a ſlight moveable covering, or thatch, to keep out the rain. The Indians bury their corn in holes in the ground, lined with mats and dry leaves.

The manner of uſing this corn in America, is various. It has this advantage over wheat, that ſubſiſtence may be drawn from your corn-fields long before the general harveſt: for the green ears roaſted, are delicate food; and as the corn ripens and grows harder, the ears boiled are good eating, with butter and ſalt. When it is ripe, the corn parched and ground into meal, is the hunting and war proviſion of the Indians, being light to carry, and affording good nouriſhment. They mix a little of it with water, and it needs no other cooking, having already paſſed the fire in the parching. The grain ſoaked in water, will part with its ſkin when beat in a large mortar with a wooden peſtle: then it is boiled, and eaten with milk. Being pounded coarſely, dry, it is alſo boiled and eaten as rice. Bag puddings, and baked puddings made of it properly, are very good. The meal is alſo boiled with water, to make what they call a haſty pudding, which they eat with butter and ſugar, or with milk. This haſty pudding, or boiled meal, being mixed with twice as much dry wheat flour, and worked into loaves, makes much better and pleaſanter bread than flour alone. All creatures fed with Indian corn, have firm and fat fleſh: the pork of corn-fed hogs, is reckoned the fineſt in the world for taſte and goodneſs; their fat is milk-white, and as hard as butter. The horſes of Virginia and Maryland, whoſe chief fodder is the leaves and ſtalks of this corn, are reckoned the hardieſt of the ſpecies, bearing moſt labour, and requiring leaſt care; and the people of thoſe countries where it is the common food of men, are healthy, ſtrong, and hardy."

This corn is thought to keep better than wheat, and has frequently been of infinite ſervice in many countries in times of ſcarcity of other grain. It anſwers all the purpoſes of the white pea, of about the ſize of which its grains are, and would certainly be a better ſubſtitute for the poor, than bean-flour, or ſome other ſorts, which have been uſed even in England, where maize may doubtleſs be cultivated to advantage in light ſandy lands, in which beans and peas do not thrive well. It is excellent for feeding poultry, either given whole to the larger ſort of fowls, or broken a little for the ſmaller. The Breſcians, in particular, who are remarkable for the fatneſs of their capons, uſe a great deal of it for this purpoſe. The Indians reckon it a good remedy in all acute diſorders; and it has been obſerved, that thoſe people are very little ſubject to the ſtone, which ſome aſcribe to their living upon this corn. They extract from its ſtalk, when green, a ſweet ſyrup, which anſwers all the ends of ſugar; and when the ſtems are diveſted of their ears, and dried, they make excellent fences, coverings of ſheds, &c.

The Indians, and ſome Engliſh, particularly where the ground is good, and has been well manured with fiſh, plant with the maize, in every corn hill, a kind of French beans, which run up the ſtem of the corn, and are ſupported by it: others plant potatoes, gourds or pumpkins, and others again ſow turnips, in the intermediate ſpaces between the hills.

Some curious perſons, by way of experiment, have planted ſeeds of only one colour in the ſame field, without any other coloured ſeeds near them, and their produce has been entirely of the ſame colour: but when the rows have been planted alternately with grains of different colours, they have interchanged, and produced a mixture of all the ſorts in the ſame row, and frequently, as was ſaid before, on one and the ſame ſpike. It is even affirmed, that they will mix with each other at the diſtance of four or five rods, if no tall fence or building ſtands between, ſo as to intercept their communication.

Mr. Miller, who mentions this, very rightly recommends the horſe-hoeing huſbandry, as, in all reſpects, fitteſt for the culture of maize; and gives the following as a method in which it has ſucceeded beyond expectation.

The

The land, which was very light and ſandy, and far from being rich, was ploughed deep before winter, and laid up in high ridges till the ſpring, when it was broken fine with the harrow. It was ploughed again in April, laid level, harrowed ſmooth, and then ſowed in drills four feet aſunder, into which the ſeeds were dropped at the diſtance of about eight or nine inches from each other. When the plants were about three inches high, they were thinned with a hand-hoe, by cutting up ſome of them where they grew too cloſe, and the intervals between the rows were ploughed ſhallow, to deſtroy the young weeds: but when the ſtems were advanced, the ground in the intervals was ploughed deep, and the earth laid up to the plants on both ſides; and when the weeds began to grow again, a third ploughing was given, to deſtroy them. This kept the ground pretty clean from weeds till the corn was ripe, as the ſeaſon did not prove wet; for otherwiſe a fourth ploughing would have been neceſſary. Each of the ſtalks of theſe plants produced from three to ſix ſpikes of grain.

Sir Richard Bulkley, who planted ſome of this corn in Ireland, from ſeed which grew in Brandenburgh, had, from each of his grains, which were ſet a foot aſunder in rows about a yard diſtant from each other, from three to ſix ſtems, and upon each ſtem three ſpikes or ears of corn, with two hundred and forty grains in each ſpike. An amazing increaſe!

Some good huſbandmen in France, have cultivated this grain upon nearly the ſame principles as thoſe which Mr. Miller points out. The little differences in their methods may not be uninſtructing: for which reaſon we ſhall here give the ſubſtance of M. Duhamel's account of their management of this corn.

"Maize thrives better in a light and ſandy ſoil, than in ſtiff and clayey land. It cannot do without dung; and the ground intended for it ſhould receive two good ploughings in March. A third ploughing, which is given towards the end of April, makes the furrows for the ſeed; and what clods remain after this, are broken by hand, the furrows then preventing the uſe of a harrow.

"A fine clear day is choſen in May, to ſow the ſeed, which is done by making at the bottom of the furrows, with a ſtick or other inſtrument, ſmall holes, into each of which two grains of maize are dropped. The furrows are a foot and a half aſunder; and the holes, at the ſame diſtance from each other, are diſpoſed in ſuch manner that they form a kind of quincunx.

"When the corn is riſen, the weakeſt of the two plants is plucked up, where both ſeeds have ſprung; and where neither of them had grown, two new grains are planted.

"Towards the middle of June, the ground is hand-hoed round each plant; and as they ſtand in the bottom of a furrow, the mould which crumbles down, from time to time, lays freſh earth to their roots, and helps to ſupport them. About the end of July, a ſlight hoeing is given them, which is the laſt; and in ſo doing the earth is laid toward the roots of the plants.

"The panicles of the male flowers, which grow at the top of each plant, and are well known not to contain any grain, are cut off about the middle of Auguſt. But care muſt be taken that the grain be impregnated before they are cut off; which may be known by the then turgid appearance of the outward covering of the ears: nor ſhould the panicles be cut off from all the plants at the ſame time; becauſe ſome of the ears are not impregnated till a fortnight after others. Theſe panicles are excellent food for cattle. When they are cut, or ſhortly after, all the leaves are ſtripped off the ſtalks, together with all the blighted and ſmutty ears: for it is ſaid that the good ears would not grow ſo large, nor the grains be ſo well nouriſhed, if they ſhould be left upon the ſtalks. All theſe leaves and ears are given as fodder to oxen; and it is remarkable, that thoſe creatures are fonder of the ſmutty ears than of all the reſt.

"The time for reaping maize is towards the end of September. The ears are then gathered by hand, and put into baſkets, in which they are carried and laid in heaps from ſpace to ſpace in the field; after which they are loaded in carts, carried home, and ſpread upon an even floor prepared for that purpoſe. They are then taken out of their ſheath or hood, and dried in the ſun before they are laid up in the granary; or elſe the grain is taken out at that time. Maize which has been well dried in the ſun will keep ſeveral years, and not be the leſs fit for ſowing. The granary ſhould be very dry, and the corn laid up in it ſhould be turned at leaſt every three months, to prevent its growing muſty, or being attacked by inſects.

"There are two ways of taking out the grain. The firſt, which is the moſt expeditious, is by threſhing it with a flail: but in this method a great deal of the corn is broken or bruiſed. The ſecond, and more common, is by rubbing the ears hard againſt the edge of a flat piece of iron. This eaſily ſeparates the grains from the ſpike, or cob, without hurting them, and this remainder of the ear is very good food for oxen.

"As ſoon as the ears are gathered, the ſtalks remaining in the ground are plucked up, and laid by for winter fodder, for oxen. The field is afterward ploughed up as ſoon as poſſible: it being the general opinion of farmers, that the roots of the maize would otherwiſe continue to ſuck up the rich particles of the earth. Whether this be true, or not, their notion is, that if this ploughing ſhould be deferred, the next year's crop would certainly ſuffer by it.

"When maize is planted only for fodder, particularly of cows and oxen, it is ſowed very thick, and harrowed in, or covered with a rake, in a good ſoil, which has been ploughed twice, and well dunged: but it is obſerved, that in theſe thick ſowings, all the female flowers are barren, and produce no grain: and it likewiſe is ſo great an impoveriſher of land, that though the ground be dunged every time it is planted, wheat never does ſo well where this corn has grown, as in the neighbouring fields where it never was."

M. Aimen, M. D. in the province of Guyenne, where great quantities of this corn are raiſed, obſerves to M. Duhamel, 1. That it is important to ſow maize rather in the beginning than at the latter end of May; becauſe, if it is ſowed early, the plants will have acquired ſufficient ſtrength before the great heats, to ſhoot out then with vigour; nor will their ears be burnt, or liable to that barrenneſs to which they are ſubject when this corn is ſowed late; beſides which, the ſtalks will be ſtronger, and their ears larger and fuller of grain. 2. That the ears of maize are greatly hurt by cutting the panicles too late; and that they ought to be cut before the hoods are open. By leaving a plant with its male flowers at every twenty feet diſtance, all the female ears will be impregnated.

In two different, but ſucceſſive years, this gentleman ſingled out two rows of maize, the plants of which ſeemed

to him equally ſtrong. He cut off the panicles of the male flowers of all the plants in the firſt row, before their hoods opened, and let the panicles of the other row remain till the uſual time of performing this operation: the conſequence was, that the female ears of the firſt row were much the largeſt and beſt filled with grain.

He likewiſe ſowed a row of maize at a diſtance from any other field planted with that corn, and cut off the panicles of that row before the hoods were opened; leaving only one plant with its male flowers at every twenty feet diſtance. At harveſt, he obſerved, 1. That all the female ears of all the plants were impregnated. 2. That the female ears of the plants which had loſt their male panicles early, were thicker, longer, and fuller of corn than any others. 3. That the female ears of the plants whoſe panicles had been cut late, were ſmaller and ſhorter, and that in ſome parts of them the grains were abortive.

To ſatisfy himſelf whether it be beſt to ſow maize thick, or thin, he planted three different ſpots of ground with this corn, on the third of April 1753. The ſeed uſed for the firſt, where the grains were placed about a foot and a half aſunder, according to the common practice of the country, in which experience had inſtructed the huſbandman, weighed one ounce and one penny-weight: the ſecond, in which the grains were only a foot aſunder, was ſowed with two ounces and two penny-weights of ſeed: and the third, in which they were but ſix inches apart, was ſowed with four ounces and a half. The firſt of theſe ſpots produced eighteen pounds and four ounces of grain: the ſecond, fifteen pounds ſeven ounces: and the third, eleven pounds two ounces. A manifeſt proof, as M. Duhamel obſerves, that ſome ſorts of grain will not thrive unleſs they are ſown very thin; and that, for want of this precaution, a great deal of corn is often loſt, and the crops are conſiderably diminiſhed.

As maize is a large plant, and requires much nouriſhment, it would certainly be right to try the culture of it with the horſe-hoe: to this end, it will be proper to plant the rows two feet aſunder, and the grains in them twelve or fourteen inches apart. All the neceſſary hoeings may then be given with the cultivator drawn by one horſe; and I believe, with Mr. Miller, M. Aimen, and M. Duhamel, that the corn will thrive the better for it, and the land be afterwards fitted for other grain. It is worth the while of thoſe who live in the countries where maize is cultivated, to try what will be the effect of this method.

MALANDERS, cracks in the bend of a horſe's knee, that diſcharge a ſharp indigeſted matter; they are often the occaſion of lameneſs, ſtiffneſs, and the horſe's tumbling.

This diſtemper is cured by waſhing the parts with a lather of ſoap warmed, or old chamber-lye; and then applying over the cracks a ſtrong mercurial ointment ſpread on tow, with which they ſhould be dreſſed, night and morning, till all the ſcabs fall off: if this ſhould not ſucceed, anoint them night and morning with a little of the following, and apply the above ointment over it.

Take of Æthiops mineral half an ounce; white vitriol one dram; ſoft green ſope ſix ounces: anoint with this often, but firſt clip away the hair, and clear the ſcabs. On their drying up, it may be proper to give a gentle purge or two; or the nitre-balls may be taken advantageouſly for a fortnight or three weeks. *Bartlet's Farriery.*

MALT, is barley prepared, to fit it for making a potable liquor called beer, or ale, by ſtopping it ſhort in the beginning of vegetation.

It is ſaid, that the ſoil on which barley grows makes a conſiderable difference in the grain, and that the barley fitteſt for malt is that which grows on a rich, light, or gravelly ſoil, and which has been raiſed from ſeed brought from a farm of a different ſoil and ſituation. The fulleſt and largeſt grains of ſuch a crop ſhould be choſen for making malt. It ſhould be heavy and perfectly ſound, and ſuch as has not ſuffered any accident in the field. Its being a little heated in the mow, is by ſome reckoned an advantage, becauſe the grain will be the more equally dried, and will conſequently the more equally imbibe water. If it has been ſo much mow-burnt as to look blackiſh when broken at the root end, or, as Mr. Combrune ſays, if it has ſuffered a heat of 120 degrees, it is unfit to make good malt. It is alſo found by experience, that barley taken immediately from the field does not malt ſo kindly as that which has been ſome time in the houſe, or mow. Special care ſhould be taken that it be free from the ſeeds of weeds; for theſe, in the malting, are apt to give the grain a bad taſte, which cannot be afterwards got rid of.

By germination, all the principles of barley are put in action. The heat which it undergoes in malting ſeparates and divides its parts; and the viſcidity which it before poſſeſſed is removed by the looſer texture of its oils, and their intimate union with the ſalt, which gives malt the ſweetiſh taſte that diſtinguiſhes it from barley.

In order to its being malted, the barley is put into a ciſtern lined with lead or ſtone, and covered with water about ſix inches deep above the barley, to give room for its ſwelling. All the good grain will ſink in the water; but, after ſtirring it, the imperfect or diſtempered grains will riſe to the ſurface. Theſe ſhould be ſkimmed off, and given to poultry or hogs, for they will never make good malt. By the water's gaining admittance into the barley, a great quantity of the air is expelled; as appears from the number of bubbles which riſe on the ſurface.

The barley is left in the water two or three days, more or leſs, in proportion to the heat of the weather and the dryneſs of the barley. A judgment is formed that grain is fully ſaturated with water, from its appearing turgid, and eaſily giving way to an iron rod dropped perpendicularly into it. Or, take a corn from the middle of the ciſtern, and hold it ſteadily, by the two ends, between the fore-finger and thumb: preſs it gently, and if it continues firm when ſo preſſed, and the ſkin does not break, it muſt ſoak longer: if it cruſhes together and feels mellow, and the ſkin crack, it is watered enough. Nicety in this is a material point, and can be learnt only by experience. If the grain ſhould be ſuffered to remain too long in the water, it would begin to loſe part of its ſweetneſs. When it has been ſteeped ſufficiently, the water is drawn off.

The water uſed for this purpoſe ſhould be that of a clear running ſtream, or rain water; or, if ſuch cannot be had, pond water, provided it be ſweet and clean, will do very well; or pump water, which ſhould be rendered ſoft, if it be naturally hard. If the water made uſe of is any way tainted, it communicates to the malt a taſte which it never loſes. Mr. Combrune adviſes the

adding

adding of lime to the water in which the barley is ſteeped: but this ſeems to be improper, becauſe it appears from Dr. Home's experiments that lime renders water hard.

From the ciſtern, the barley is laid in a regular heap, or couch, where it muſt remain thirty hours, or till it contracts a heat. It muſt then be worked in one or more heaps, and turned every four, ſix, or eight hours, according as the weather is cold or hot. When it begins to ſpire, it ſhould be turned every three or four hours, according to the temperature of the air; and as it comes (for ſo its ſpiring is commonly termed) the heap muſt be ſpread thinner to cool it, leſt it be heated too much, and the germination be carried on too faſt, by which the oils would be too much conſumed. The turning of it muſt be continued in proportion as it is more or leſs ſlow in growth, ſo that it may be brought tolerably dry to the kiln. When the roots begin to deaden, the couch muſt be thickened again, and often turned, that the growth of the roots may not revive. At this time, the ſpire ſhould be near piercing through the outer ſkin of the barley: for if it grows quite out, the ſtrength of the malt will be too much conſumed. After the malt is made thus far, the common practice is to lay it at once on the kiln: but the beſt way is to gather it all up in one heap, to let it lie in that ſtate twelve hours, and then to turn it every fourth hour, during the ſpace of twenty-four hours.

No perſon ſhould be ſuffered to tread on the malt with their ſhoes, while it is on the floor; becauſe many grains are inevitably bruiſed thereby, and theſe, vegetating no longer, afford the roots of the other grains a ſubſtance into which they extend their fibres, and are by that means intangled in bunches: and beſides this, the bruiſed corn acquires a degree of putrefaction which taints the liquor made of the malt intermixed therewith. Equal care ſhould alſo be taken, that the grain be not bruiſed by any other means.

Mr. Combrune thinks, that the time moſt proper for malting is when the temperature of the air is ſuch that barley begins naturally to germinate, at which ſeaſon the thermometer marks from between thirty-two to forty degrees. How far that time may be extended, experience alone can determine. The warmer the weather is, the greater muſt be the diſadvantage under which the maltſter labours; becauſe the motion of the fluids is then ſo ſtrong, that the proceſs goes on too quick, and the finer parts are apt to fly off; the conſequence of which is, that inſtead of a ſweet, the malt inclines to a bitter taſte, the oils being turned rancid. This is ſo univerſally experienced, that brewers carefully avoid purchaſing what is termed latter made malt.

The grain thus prepared for drying is ſpread on the kiln, where, meeting with a heat greater than is ſuited to vegetation, its farther growth is ſtopped. It is ſpread on the kiln three or four inches thick, and turned every three or four hours. The laying of it thicker is attended with inconveniencies, among which is particularly its being unequally dried; and therefore that ſhould be avoided. The ſtrength and duration of the fire is different, according as the malt is intended to be dried, pale, amber, or brown. The pale malt requires more leiſure, and leſs fire, than the amber or brown.

Pale and amber malt are dried with coke or culm, which not emitting any ſmoke, give the malt a brighter colour, and do not communicate that bad reliſh which malt has when dried with wood, ſtraw, &c. the ſmoke of which taints it. Coke is beſt, becauſe its fire gives a ſteady and conſtant heat, whereby the malt is dried uniformly. If wood, or any vegetable fuel is uſed, it ſhould be extremely well dried, in order that, being as free as poſſible from moiſture, it may yield the leſs ſmoke.

The ſize of the malt kiln is generally proportioned to the quantity of malt for which it is intended. Some build their kiln ſquare, and others make it round; but this laſt is undoubtedly the beſt form, becauſe the heat of the fire is more equally diffuſed therein, and the grain is of courſe more equally dried. Various ſubſtances have been made uſe of for covering the kiln, ſuch as tiles, plates of tin, and wire: of theſe, the wire is to be preferred, becauſe it does not contract ſo great a degree of heat as to parch the grain in contact with it: but, for this very reaſon, hair cloth is preferable to any other covering; becauſe, when any part of the malt is in immediate contact with a ſubſtance much more ſolid than itſelf, and therefore capable of receiving a proportionably greater degree of heat, the malt in contact with that heated body is parched or burnt, by heat which is not equally diffuſed through the whole maſs. which maſs cannot therefore be all equally heated. The hair cloth is ſpread upon ſmall wooden rafters, and theſe are ſupported by bars of iron laid acroſs the kiln.

An ingenious and attentive maltſter marked the degree of heat in the malt whilſt on the floor: and the reſult of his obſervations in this reſpect is as follows. During the firſt ten days that the malt was on the floor, the heat in it was between 50 and 60 degrees. During the next three or four days, the heat was increaſed from 60 to 65 and 67 degrees; and during the laſt days of its lying there, to 80, 84, and 87, which laſt was the degree of heat when the malt was put on the kiln. There cannot be any abſolute rule as to the difference of heat during the different times in the proceſs of malting, becauſe it muſt be ſuited to the heat of the air: at leaſt we have not yet ſufficient data whereon to found ſuch a calculation. The heat of the malt on the kiln when fit for pale malt was 120 degrees, and when it was fit for brown the heat was 147.

This intelligent artiſt's obſervation, that the malt was fit for what is called pale malt when its heat was at 120 degrees, ſuggeſts a caution which ſhould be moſt carefully attended to, namely, that whatever colour it be intended to give the malt, the heat at firſt ſhould always be the ſame: thus, for example, malt which is dried to the degree of high brown, ſhould firſt be rendered pale malt, then amber, and ſo on progreſſively; not by a ſudden increaſe of the fire, but by a longer continuance thereof. In this manner, the whole body of the grain is equally and gradually dried; whereas a ſtrong and quicker fire would parch, or as it were ſinge the outſide, while the internal parts remain moiſt: and as that moiſture is afterwards evaporated, it muſt crack the ſurrounding hardened cruſt, whereby the grain is again damaged in another reſpect.

As ſoon as the malt is dry, it muſt be removed from the kiln, and ſpread thin, that it may cool to the temperature of the air. It cannot be ſuppoſed, that any of its parts are capable of retaining the fire in ſuch manner as not to ſuffer it to eſcape; though ſome have conceited that they do. In proportion as malts are dried, their particles are more or leſs ſeparated, and coming in contact with water, they

ſtrongly

ſtrongly attract from it particles which fill up their interſtices. In maſhing, this action between the malt and the water generates a ſmall degree of heat, but no way durable; though from hence aroſe the opinion, that brown malt is full of fire.

Barley may, at a medium, be ſaid to loſe, by malting, one fourth part of its weight, including what is ſeparated from it by the roots ſcreened off: but this proportion varies, according as it is more or leſs dried.

The condition of the barley, as to its greenneſs or ripeneſs, at the time of its being gathered in, is clearly diſcernible when it is malted. If it was gathered green, it rather loſes than gains in quantity, the malt becomes of a ſmaller body, appears ſhrivelled, and often is unkindly hard; whilſt, on the contrary, that which was cut at full maturity increaſes in malting, appears plump, bright, and clear, if properly carried through the proceſs, and, on being cracked, readily yields that fine mealy ſubſtance ſo much deſired by the brewers.

Malt which has not had a ſufficient time to ſhoot, ſo that its plume, or acroſpire, as the adepts in malting call it, may have reached to the inward ſkin of the barley, remains charged with too large a quantity of its unattenuated oils. All thoſe parts which have not been put in motion by the act of germination, will, when laid on the kiln to dry, be ſo hardened, as not to be ſoluble in water, and conſequently will be loſt to the ſtrength of the drink.

When malt is ſuffered to grow too much, or until the ſpire has ſhot through the ſkin of the barley; though all that is left be malt, yet, as too large a portion of its oils will have been expended in vegetation, the malt will be greatly diminiſhed in proportion to what it ought to have been, and what remains cannot be fit to brew drink for long keeping, becauſe of the loſs of the oils.

Malt which has been duly worked on the floor, will, if it has not been ſufficiently dried on the kiln, be apt to germinate or ſprout afreſh; perhaps to conceive ſo great a heat as to take fire; and ſhould it continue long with a moderate degree of heat, the leaſt evil that can be expected, is that it will grow mouldy and have an ill flavour.

Malt well worked, but over-dried, will be ſo hardened, or its ſaponaceous quality will be ſo deſtroyed, that it will not imbibe from the air that moiſture which is neceſſary to mellow it, and render it fit for brewing: for when it has been previouſly ſoftened by the moiſture of the air, it mixes more eaſily and more intimately with the water, and by that means yields a more copious extract, than it would otherwiſe do.

Malt juſt, or but lately, taken from the kiln, remains warm a conſiderable time. Until it becomes as cool as the ſurrounding air, it does not mellow by the addition of a due quantity of moiſture from the air: and the wort made of ſuch malt requires a much longer boiling before it breaks, than that which is made of malt ſome months old.

The practice of thoſe maltſters who ſprinkle water on malt newly taken from the kiln, to give it the appearance of having been made a proper time, or, to uſe their own expreſſion, to plump it, is highly blameable. It is, in fact, a downright fraud, practiſed chiefly becauſe leſs grain then fills the buſhel: but a farther evil is, that if it be not uſed ſpeedily, it heats, ſoon grows mouldy, and ſuffers great damage.

Malt dried on a kiln not ſufficiently heated muſt require a proportionably longer time for it to receive the due effect of the fire: for want of which it will be in the ſame ſtate as malt not thoroughly dried. Or if the fire be too quick, or too fierce, inſtead of gently evaporating the water from the corn, it ſcorches the outward ſkin, and ſeparates it from the body of the grain. The malt to which this happens is called blown malt; of which Mr. Combrune obſerves, that, by the internal expanſion of its parts, it occupies a larger ſpace than it ought to do. He adds, that if ſuch a fire be continued, it changes ſome parts of the grain into ſo brittle a ſubſtance, that the malt is ſaid to be glaſſy. The particles which are thus hardened will not diſſolve, or but in ſmall proportion: ſo that they frequently occaſion an almoſt total want of extract, which, in the phraſe of the art, is termed, ſetting the griſt.

The goodneſs of malt may be known by the following marks. Bite a grain of it aſunder, and if it taſtes mellow and ſweet, breaks ſoft, and is full of flour from one end to the other, it is good. If it has a round body, and upon putting ſome grains of it into water, they ſwim on the ſurface, it is good. Barley ſinks in water, and malt that is not well made will do the ſame: but it is to be obſerved that this is not an invariable proof, becauſe, if the malt be broken, or in the leaſt cracked, it will take in water, and ſink. Malt that is rightly made will not be hard, but of ſo mellow a nature, that if drawn over an oak board, acroſs the grain, it will leave a white line upon the board, like a mark of chalk. Its ſmell alſo may be conſulted; for malt, though otherwiſe good, may have contracted an ill ſcent from the fuel, or from the water uſed in the ſteeping.

Before malt is ground, it ſhould be freed from the tails and duſt, which would otherwiſe heighten the colour of the wort, render the liquor muddy, and give it a bad taſte, which could not afterwards be got rid of. The cylindrical ſieve will be of excellent uſe for this purpoſe.

The malt muſt be broken, in order to its communicating its virtue to the water. If it be ground too ſmall, its flour will mix too freely with the water, and cauſe the wort to run thick. Many are of opinion that the beſt way is only to crack it, ſo that none of the grains may come out whole: for the intent is, that the water ſhould draw out an extract, but not be mixed with the mealy part, in the manner of a paſte or gruel. Some think that malt is better ground by a ſtone mill, than by a ſteel one, becauſe the former bruiſes it, and the latter only cuts the grains.

After the malt is ground, it ſhould lie ſometime to mellow in a cool room where no ſun comes. The time for this is different, according to its kind. Brown malt may be ground at from three to fourteen days before it is uſed, in order that the corn, which is rendered uncommonly hard by that degree of drying, may be gradually ſoftened by the moiſture in the air; by which means it will become the more ſoluble in water. The pale malts require only one or two days. After lying thus in the air, leſs maſhing ſuffices; the ſtrength of the malt is more perfectly extracted, and the beer will be conſiderably ſtronger than it would be with the ſame quantity of malt taken directly from the kiln. Care muſt be taken that it get no damage in lying.

Mr. Combrune obſerves, that malt imbibes moiſture more readily by being ground and expoſed for ſome time to the air, than it does when whole; and that as the dampneſs

neſs thus abſorbed by the grain is in reality ſo much cold water, malt which has been long ground requires to be maſhed with hotter water than it would otherwiſe be neceſſary to uſe. *See the article* BREWING.

The reader is obliged for the following uſeful obſervations on the art of making malt to a very ingenious gentleman, who has practiſed the art many years.

Experience, and a conſtant obſervation on effects and their cauſes, have, ſays he, made me maſter of ſome pieces of knowledge relative to this ſubject, which your farming readers may probably think worthy their attention: the reſult of this experience I ſhall lay before them.

The firſt thing I ſhall mention, with regard to malt, is the benefit of changing the water whilſt it is ſteeping.

Some maltſters think this change of water no ways neceſſary; others, on the contrary, approve of it, but do it indiſcriminately in the ſame proportion during the whole ſeaſon. They are in both reſpects wrong; for the times when the water requires to be changed oſteneſt are at the beginning and latter end of the ſeaſon, in autumn and ſpring, when the weather is warm; for in the middle of the winter the weather is too cold to admit of the water being at all changed to any advantage. Suppoſe the barley to be left in ſteep forty-eight hours in the ſpring: if the weather is inclinable to be warm, the water may be in that ſpace of time changed three times; in other caſes twice may be enough; but the beſt rule to go by, is that which follows.

Every maltſter muſt know, that in the autumn and ſpring, if barley is left too long on the ſteep in the ſame water, the water will grow ſlimy, and ſometimes ſour: now I would adviſe the maltſter to watch the changes of the water, and when he finds that it is ſmooth and oily to the touch, and that it is inclinable either to ſmell or taſte ſour, let him by all means have it inſtantly changed; but he muſt obſerve, if he regards his intereſt, a particular method even in doing this.

The uſual way of changing the water is, firſt to draw off that in which the barley was ſteeping, and afterwards by pails full, or by pumping, fill the ciſtern again.

This I do not approve of, becauſe the barley when the water is drawn off lies cloſer, and is apt, in a very ſhort ſpace of time, to heat: this is a great damage to the commodity, and, without precaution, a conſiderable loſs enſues. Now my method has always been, firſt to get a hogſhead of water in readineſs near the ciſtern; which I cauſe to be thrown on the barley the inſtant the firſt water is drawn off; and as a hogſhead of water is ſufficient to wet eight buſhels of barley, I add afterwards as many hogſheads, ſave one, as my ciſtern will wet quarters. By theſe means I avoid the danger of the barley heating in the ciſtern.

The conſequences of not changing the water whilſt the barley is ſteeping, are often fatal to the malt.

I have already obſerved, that in the ſpring and autumn it is neceſſary to change the water often in which the barley is ſteeped: it ſhould likewiſe be remembred, that in theſe ſeaſons the making of malt, in all its parts, is a very critical buſineſs; particularly it is then neceſſary that the beds, or couches, ſhould be frequently turned, or the malt will not come kindly; but the tap root will be apt to ſhoot forth vigorouſly, ſtarving the other roots, and preventing them from accompanying it in its growth: this muſt be checked, and the remedy is, to turn the couch often, ſpread it thin, and give it a ſufficient quantity of air, at the ſame time keeping it cool and temperate. This will ſtop the progreſs of the firſt root, give the others time to ſprout, and the barley will malt kindly and regularly.

A thin ſkinned fine coated-barley is beſt for making malt, and is not the worſe for not being very full bodied; yet would I by no means recommend a lean, half-ſtarved unripe grain.

Barley, which has grown on lands highly manured, is not ſo good for making malt, as that which has been produced by land of a moderate richneſs without any manure: in fact, a luxuriant ſoil, whether naturally ſo, or enriched by art, is not, in general, beſt for yielding barley for the maltſter's uſe.

For the reaſons above mentioued, never chuſe to buy barley from the farmers who have large crops, as it is moſtly a full bodied grain they have to ſell. I prefer, for malting, a grain which is the produce of a ſoil that is rather poor than rich, rather light than ſtrong, and more inclined to a gravel than a clay.

This grain is clean-coated, taper, and elegant in its form, is full of flour, almoſt tranſparent when watered, and will be ſufficiently wetted in forty-eight hours.

This grain increaſes in the malting, fills the buſhel well, and makes a fine, ſweet, wholeſome, clean, full-bodied malt, from which the beſt of beer may be brewed, either brown or pale, according as the malt has been dried higher or lower.

Now I have mentioned drying of malt, a few cautions on that head may not be amiſs.

My practice has been to give my malt as much drying as I could on the floor: this is not only a great ſaving of fuel to me, but is alſo attended with ſeveral other advantages.

I find that my malt, by being thus gradually diveſted of its outward moiſture, does not ſhrink ſo much when it comes to be laid on the kiln; of courſe it meaſures to more advantage: it is beſides of a better quality, having acquired no foreign taſte in drying.

It may very eaſily be obſerved, that if malt is laid very damp on the kiln, a thick miſt, or ſmoky vapour, will immediately ariſe from the ſurface of it, which being repelled and condenſed by the cold circumambient air, falls again on the malt, where, by the heat from the furnace, it is a ſecond time rarefied, and aſcends in clouds of ſteam.

This alternate rarefaction and condenſation of the moiſture is of great diſſervice to the malt, giving it often a diſagreeable muſty flavour, and making it beſides more unfit for keeping.

Now, by my method of ſuffering the malt to receive a part of its drying on the floor, this inconvenience is, in a great meaſure, avoided; for the groſs moiſture is already evaporated before it is laid on the kiln, and that which remains creates no great degree of ſteam, provided the fire in the furnace is not at firſt made to burn too fierce.

With this precaution I have often made pale malt as fine as I have any where ſeen, ſuch as ſome gentlemen, who long dealt with me, frequently, nay, conſtantly, praiſed. In drying this malt, I took care that there was, during the whole time it was on the kiln, but a very moderate, yet equal, fire in the furnace.

If

If I had an inclination to have any malt high dried (for ſome like brown malt better than pale) when the moiſture was nearly evaporated, I cauſed the fire to be gradually encreaſed till it roared again in the furnace, taking care that the malt ſhould be properly ſtirred, leſt it proved kiln-burnt; and by this method I had a fine, ſweet, brown malt, fit for making harveſt beer, ſuch as ſome farmers are very fond of brewing.

Many are of opinion, that brown malt, uſed in the ſame proportion with the pale, will make the ſtrongeſt beer; but this is certainly a miſtake; for I have often made the experiment with great preciſion, but could never find any material difference, and what difference there was at any time, ſeemed to me to be rather in favour of the pale than the brown malt: this may eaſily be accounted for, as the flour in the pale malt always remained ſound and uninjured in the drying; whereas the brown malt would ſometimes, notwithſtanding all the care of the maltſter, be injured or parched by the fire, and that part which was parched had of conſequence loſt its ſpirit and virtue.

I muſt, however, on this occaſion, make one neceſſary remark, which is, that ſome pale malts are ſlack dried: theſe, I own, make a raw unwholſome liquor, which will not keep well; but if the pale malt is gradually and ſlowly dried by an uniform gentle heat, it will certainly anſwer the character I have already given of it, and will, beſides, (I have experience for my voucher) keep as well as any brown malt whatever.

Maltſters in general are too little nice in the barley they buy. I have already ſaid ſomething on this head, to which I ſhall add, that I would by no means have them ever bargain for mixed grain: what I mean by mixed grain, is barley grown on various ſoils, and in different fields. There is a ſure diſappointment in buying ſuch grain, as the kerns will ſpire at different times, and ſome of them not at all; ſo that, after the couch is dried, ſome part of it will not be half malted, and a great deal of the remainder not malted at all.

In order to avoid this misfortune, for ſuch it is, as the maltſter's cuſtomers will, with too much reaſon, find fault with his commodity, let him by no means attempt to buy tythe barley, for that he is ſure is mixed: I experienced myſelf, many years ago, a great loſs by a purchaſe of the kind. A neighbouring farmer, with whom I was well acquainted, brought a ſample of barley to market: I looked at it, and though it was not very fine, I bought it, on account of his letting me have it ſix-pence a quarter cheaper than I could then buy of others: the lot conſiſted of one hundred quarters; but when it came home, and I had tried ſome of it, I think about ten quarters, I was greatly ſurpriſed to find the malt ſo bad, when examining the barley with great attention, I ſoon diſcovered the reaſon of it. Meeting the farmer, of whom I had bought it, within a day or two afterwards, I aſked him how he came to ſell me mixed barley, adding, that I always thought he kept his grain with more care ſeparate; he ſoon unravelled the myſtery, by telling me, that it was the parſon's barley, not his own, which he ſold me.

When I heard this, I was not a little diſpleaſed; however, reſolving to make the beſt of a bad bargain, I carried a ſample of it to market rhe next day, and ſold it to a hog-feeder for eighteen-pence a quarter leſs than I gave for it. This was ſome loſs; however I was glad to get off ſo well, as I would not have made the whole into malt, and have impoſed on my cuſtomers for an hundred pounds.

To ſhew that I am not ſelf-intereſted, I will inform your readers of a method by which they may diſcover whether malt has been made of mixed, or in part unripe barley. Take a bowl of water; throw into it a couple of handfuls of the malt; give it a gentle ſtirring, and the barley which has not been malted will ſink to the bottom; the half-malted grains will have one end ſunk, being in a vertical poſition; and the true good malt will ſwim. This experiment I have often made, and never found it deceive me.

The ſame barley, though ever ſo good, will not malt alike well at all times: for, inſtance, take it as ſoon as it is houſed, it comes well, but whilſt it is in its ſweat, by no means; yet after it has none ſweating, it comes well again.

In the ſame manner, barley which has been got in early in a very dry ſeaſon, makes but indifferent malt; whereas the ſame barley, if it is left abroad till rain falls on it to looſen the huſk from the kernel, malts very well, and yields a large increaſe.

Alſo, old barley, mixed with that of the laſt harveſt, does not malt well, for the reaſons above mentioned; it does not all ſpear, or put forth its beard, at the ſame time.

Theſe I know are niceties which few maltſters attend to; yet I am certain that an obſervance of them, and ſome few more particulars, would increaſe their profits nearly ten per cent.

A great many maltſters in the counties of Hertford and Eſſex, make prodigious quantities of malt for the London market; and there are often diſputes happen between the maltſters and the factors and buyers at Mark-lane, about the malt not holding out meaſure; the reaſon of which many of the country dealers are unacquainted with, and therefore know no other way of guarding againſt it, than by throwing in a buſhel or two extraordinary: this is ſome abridgment of their profits, and is beſides often unneceſſary. One reaſon for this deficiency, is the avariciouſneſs of the maker, who is willing to have as large an increaſe as poſſible, to the amount of ſix pecks in eight buſhels; whereas, if the malt is intended for the London market, four pecks is all that can, with propriety, be allowed; for it muſt not be drawn too long; and this malt requires more cleaning by the ſcreen, &c. than that ſold in the country.

Malt, if it is not thoroughly cleaned, will heat in the hold of the veſſel that carries it; and the tails, being looſened, will fall off; the neceſſary conſequence of which muſt be a deficiency when it comes to be meaſured a ſecond time at the wharf or ware-houſe: now, to prevent any altercation or diſpute, let the maltſter always cauſe his commodity to be well ſcreened before it is meaſured into the ſacks to be carried on ſhipboard: he need then put up no more than the meaſure; he will gain himſelf a character as a clean good workman; and I will anſwer for it, that the factors, if he makes his malt according to ſample, will readily give him one ſhilling a quarter more than his neighbours.

MALT-DUST, the duſt, &c. that ſeparates from the malt in the act of drying.

The

The following obſervations on the benefit of malt-duſt, as a manure for a ſtiff ſoil, with a relation of ſome experiments made to aſcertain its virtues, appeared in the *Muſeum Ruſticum*, *vol.* III. *page* 277.

For the benefit of your farming readers, ſays this gentleman, I ſhall communicate a few experiments I made ſome time ſince, in order to try the virtue of malt-duſt as a manure for a crop of wheat.

I had often heard it aſſerted, that malt-duſt was much better ſuited, as a manure, to barley than wheat; for the latter lying a whole year in the ground, and the malt-duſt being ſown with it, the virtues of the manure were exhauſted long before the ſummer, when the corn principally wants nouriſhment; being advanced in its growth, and ſerved chiefly to make the wheat winter-proud.

Others, contradicting this aſſertion, ſaid it was beſt for wheat, and made it appear, that it often cauſed very good crops of corn, particularly after a hard winter.

Being determined in my own mind to try ſome experiments, in order to determine this matter, I pitched upon a field of ten acres, which had borne a good crop of horſe-beans; after which it was ſown with turnips, which being fed off, it was ſummer-fallowed, being intended for wheat.

The ſoil was a ſtiffiſh loam; it was in good heart, and tolerably clean.

I divided this field by deep furrows into ten equal parts, each containing one acre, numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10.

The whole field, during the courſe of the fallowing had four ploughings, which reduced it to a fine tilth.

When wheat ſeed-time came, I ſowed number 1. broad-caſt, with three buſhels of wheat, and ploughed it in, laying on no manure whatever.

Numb. 2. I ſowed with the ſame quantity of wheat, after which I ſtrewed over it ten quarters, or eighty buſhels of malt-duſt, and ploughed that and the ſeed in together.

Number 3. I ſowed alſo with wheat in the ſame manner, except that I deferred ſtrewing on the malt-duſt, till the latter end of January.

Number 4. had a dreſſing of dung in the ordinary way, and was ſowed with three buſhels of wheat like the other parts.

Number 5. was dreſſed by ſheep-folding, and was alſo in like manner ſown with wheat.

Number 6. was ſown with wheat in the ſame quantity: and in February, after ſowing, received a half dreſſing of very rotten dung; which had been ſeveral times turned and mixed.

Number 7. after receiving a ploughing in the ſpring, was ſown with ten pecks of barley, which was harrowed in, and no manure at all applied.

Number 8. was ſown with barley, as above, but had ten quarters of malt-duſt laid on it.

Number 9. had in the winter a good dreſſing of dung, and was in the ſpring ſown with the ſame quantity of barley.

Number 10. was ſown with barley, like number 8. only it had five inſtead of ten quarters of malt-duſt laid on it.

It may be neceſſary, perhaps to obſerve, that all the pieces of wheat were ſown the firſt week in October, and all the barley the ſecond week in March.

Soon after Chriſtmas I went to take a view of my wheat, when I found that the acre marked number 2. looked moſt forward and flouriſhing; though I muſt own there was in appearance but little difference between that and number 4.

The numbers 1, 3, and 6, neither of them looked ſo vigorous as thoſe already noticed; and number 5. ſeemed rather thin on the land; but the wheat plants were in good condition and healthy.

In May I took another view of my wheat crops, and found number 1. tolerably clean, and promiſed well.

Number 2. gave me hopes of a large crop, and was ſurpriſingly clear of weeds.

Number 3. was greatly improved ſince the laying on of the dreſſing of malt-duſt.

Number 4. looked very vigorous and ſtrong, but was very foul, having ſeveral ſorts of weeds not to be met with in other parts of the land.

Number 5. was thin of plants, and they did not branch much; however, they ſtill ſeemed healthy and ſtrong.

Number 6. was like number 3. greatly improved; but it was foul, and, what appeared ſtrange to me, had many weeds of a nature quite different from thoſe with which number 4. was infeſted, though the dung laid on both theſe parts was taken from the ſame heap.

I, at this time, alſo looked at my pieces ſown with barley, when I found number 7. promiſing and clean.

Number 8. was forwarder, and flattered me with the proſpect of a large crop.

Number 9. was forward and fine, but foul with weeds.

Number 10. bore much the ſame appearance as number 8. and promiſed as well.

At harveſt number 2. of the wheat was firſt fit to reap, after which ſucceeded number 4. the reſt were ready nearly at the ſame time.

Of my barleys, number 8. and 10. were firſt ready to mow.

I ſuppoſe it is unneceſſary to obſerve that thoſe crops which were cleared of weeds were the ſooneſt fit for carrying.

I ordered theſe crops to be all laid ſeparately; and as I was obliged, juſt after Michaelmas, to go up to London, about ſome particular buſineſs, I left orders with my bailiff, that they ſhould all be ſeparately threſhed and dreſſed as early as might be in the winter.

The produce of the ſeveral crops was thus diſtinctly noted to me, for I had ordered that particular care ſhould be taken not to mix one with the other, and my orders were, I found, on enquiry, punctually carried into execution.

	Buſh.	Pecks.
Number 1. unmanured, yielded of wheat -	20	1
Number 2. manured with malt-duſt when ſown —— —— ——	28	3
Number 3. manured with malt-duſt after Chriſtmas, by way of top-dreſſing ——	41	0
Number 4. manured with dung in the ordinary way —— —— ——	32	2
Numb 5. folded with ſheep —— ——	29	3
Number 6. dreſſed with rotten dung in February —— —— ——	30	0
Number 7. unmanured, yielded of barley	32	3
Number 8. manured with ten quarters of malt-duſt when ſown —— ——	48	0
Number 9. manured with dung in the winter	40	2
Number 10. manured, when ſown, with five quarters of malt-duſt —— ——	44	0

I muſt, with your leave, treſpaſs upon your reader's patience, till I make a few obſervations on the above ſtate of the produce of my crop.

Firſt, I conclude, that when malt-duſt is uſed as a manure for wheat, it is beſt to lay it on by way of top-dreſſing after the corn is come up, as the crop of number 3. yielded above twelve buſhels more than that of number 2. and I am apt to think that the virtue of the malt-duſt laid on number 2. was exhauſted before it could be of any eſſential ſervice to the crop; whereas, in number 3. the manure began to yield forth its virtues juſt as the wheat plants began to be in want of a freſh ſupply of nouriſhment. It was alſo obſervable, that the grains of wheat which grew on number 2. were thinner, and had leſs ſubſtance, than thoſe of number 3. the grain of which was fine, plump, and heavy.

The produce of number 4. convinces me that malt-duſt is, in many caſes, a better manure for wheat than dung, not only as it gives a larger encreaſe, but alſo becauſe it does not ſtock the land with deſtructive and devouring weeds.

The wheat grown on number 5. was as fine as that of number 3. but conſiderably leſs in quantity, as appears by the account.

I do not much approve of the method purſued in number 6. yet is it a good alternative, if the farmer happens to have too little dung to dreſs all his fallows.

I judge alſo malt-duſt to be a very good and profitable manure for a barley crop; but the yield of number 10. being forty-four buſhels, and of number 8. only forty-eight buſhels, which laſt is not an encreaſe in proportion to the additional quantity of manure laid on, I thence judge that eight quarters, or ſixty-four buſhels, of malt-duſt, is the proper quantity of malt-duſt to lay on an acre for a barley crop, and that at the time of ſowing.

When I ſpeak of malt-duſt, I mean the kiln-duſt, which falls from the malt in drying: as to the tail-duſt, which falls through the ſcreen whilſt the malt is cleaning before it is put up in ſacks, that may be applied to a better uſe, being generally given to pigs, and often to cows, in which laſt caſe it makes them give a great deal of milk.

It has been ſuggeſted that the virtue of malt-duſt, as a manure, laſts only for one crop; but this is a miſtake, for when this manure is laid on in January or February, a good crop of barley may be had after the wheat.

It (I mean malt-duſt) is of a very warm nature: this has induced many farmers to think that it will burn a crop; and I will not anſwer for it but it might do ſo on a hot gravelly ſoil; but on clay land, or a ſtiff-loam, it ſeldom or never does any damage: and indeed the only danger is a dry time enſuing after it is ſpread on the land, for the firſt ſhower of rain waſhes it in, and ſecures the crop from all hazard of being burnt.

Many of my acquaintance, beſides myſelf, have found that malt-duſt is for a ſtiff ſoil a better manure than dung; but the diſpute among them was, whether it was moſt profitable to lay it on when the wheat was ſown, or by way of top-dreſſing in January or February: however, ſince I made the above experiments, they are all converts to my opinion, and are determined in future always to dreſs their heavy wheat land with it after Chriſtmas.

One thing more in recommendation of this my favourite manure let me add before I conclude, that nothing ſurpaſſes it when laid on cold graſs grounds, to the amount of about eight quarters, or ſixty buſhels, on an acre, but not leſs. Such as have not ſeen its effects in this way applied, would be ſurpriſed at the large encreaſe of ſweet feed which it occaſions: in ſhort, whoever finds it neceſſary to dreſs ſuch land, and can get malt-duſt in a ſufficient quantity, will do well to uſe it, as they will be puzzled to find any thing in the extenſive circle of manures better adapted to the purpoſe.

MANGER, the place or veſſel in which the horſe's corn is put.

MANURE, a general name for ſoil of all kinds laid upon land to improve it. *See* DUNG.

The following Letter ſent to Dr. Templeman, *Secretary to the Society for promoting Arts, &c. to be by him communicated to the Committee of Agriculture, in Recommendation of a new Manure, is of too much Importance to be omitted here.*

"SIR,

"As a farmer, like a chemiſt, ſhould loſe none of his materials, but make even his waſhings, runnings, and reſiduums, turn out to his advantage, I have ſent you ſome account of an experiment I have made in manuring of land, which I beg you will lay before the committee of agriculture, that they may communicate it to others.

"I am poſſeſſed, Sir, of a farm of near three hundred pounds a year, and have in my yard, what you uſually ſee in moſt farmers yards, two receſſes or pools, as reſervoirs of dung and water. Theſe reſervoirs in wet weather are continually running over; and of courſe part of the matter contained in them is carried off, by the neceſſary drains, into the highways, ditches, and rivers.

"As much of the eſſential quality of the dung is loſt in this manner, (for part of the ſalts, whether fixed or volatile, will be waſhed into the pools, and when they overrun, will be conveyed into the ditches, &c.) I thought it a part of good huſbandry to carry this ſuperabundant water, or manure, (for ſo we may juſtly call it) on my land, which I did by means of a watering-cart, not unlike thoſe with which the roads near London are watered in the ſummer-time to allay the duſt.

"That the experiment might be the more obvious and certain, I firſt tried it (in the beginning of March, 1763) on a few acres in the middle of a large meadow, and on ſome lands in the middle of a large field of wheat, where, in a little time, I found a conſiderable encreaſe, in growth, both of graſs and grain; and at hay time and harveſt, both the one and the other were much better crops than what the ſame lands produced that were not ſo manured.

"As a man, or even a boy, with one of theſe carts, and one horſe, may manure a great deal of land in a day, provided it be near the yard, I would recommend the practice to all my brother farmers; for the expence is nothing, but the value of the time of the boy and the horſe; and the encreaſe, by what I have ſeen, will be very great.

"This manure may be alſo laid, to great advantage, on land that is freſh ſown with barley, oats, or any other grain; but on graſs it ſhould be only laid in the winter time, when the rains will waſh the ſalts off the blade; or in the ſpring, when the lands are laid up for hay; as the cattle will not feed on the graſs, while the dung, or ſalt, adheres to the blade of it.

"This dung-water ſhould likewiſe be carried on the land, not at a time when it rains, but in the dry weather, and at a time when the dung-water in the pools is

of a deep brown colour, and ſtrongly impregnated with ſalts. By this means the land may be manured from time to time, and the pools kept almoſt empty for the reception of freſh matter every time it rains; and nothing will be loſt.

MARE, the female of the horſe. *See the article* HORSE.

Such mares as are deſigned for breeding, ought to be as free from defects as poſſible, and ſhould, no more than the ſtallions, have either moon-eyes, watery-eyes, or blood-ſhot-eyes; they ſhould have no ſplint, ſpavin, or curb, nor any natural imperfection; for the colts will take after them: but choice ſhould be made of the beſt and ableſt, the moſt high ſpirited, beſt coloured, and fineſt ſhaped; and the natural defects that may be in the ſtallion, ſhould be amended in the mare, as well as that which is amiſs in the mare ſhould be amended in the ſtallion.

As for her age, ſhe may be covered when three years old; but the moſt convenient time is after four, when ſhe will nouriſh her colt beſt; and though ſhe may breed till ſhe is thirteen, yet ſhe is not fit for it when ſhe is paſt ten, for the colt of an old mare is commonly heavy. Before a mare is covered, ſhe ſhould be in the houſe about ſix weeks, during which time ſhe ſhould be well fed with good hay and oats well ſifted; and in order to render her conception the more certain, near a quart of blood may be taken from each ſide of her neck, about five or ſix days before covering. Another method to bring a mare in ſeaſon and make her retain, is to give her, for the ſpace of eight days before you bring her to the horſe, about two quarts of hemp-ſeed in the morning, and as much at night; and if ſhe refuſes to eat it, to mingle it with a little bran or oats, or elſe to let her faſt for a while: and if the ſtallion alſo eat of it, it will greatly contribute to generation.

Mares go with foal eleven months and as many days as they are years old; and therefore the propereſt time for covering them is in the beginning of June, that ſhe may foal the May following, when there will be plenty of graſs, which will afford the mares a great abundance of milk for nouriſhing their foals: but a mare ſhould never be covered while ſhe is bringing up her foal, becauſe the foal to which ſhe is giving ſuck, as well as that in her belly, will be prejudiced by it, and ſhe herſelf ſooner ſpent. After covering, let her, for three weeks or a month, have the ſame diet as before, and kept clean in the ſtable till the middle of May, with her feet well pared and thin ſhod: take her in again about the latter end of September, if not before, and keep her to the end of her foaling. If ſhe cannot readily bring forth, hold her noſtrils ſo as to ſtop her taking wind; and if that will not do, diſſolve madder, to the quantity of a walnut, in a pint of ale, and give it her warm. In caſe ſhe cannot void her ſecundine, or after-burden, boil two or three handfuls of fennel in running water, then put half a pint of that liquor into as much ſack, or, for want thereof, into a pint of ale, with a fourth part of ſallad-oil, mixed together, and pour it luke-warm into her noſtrils, holding them cloſe for ſome time: otherwiſe give her green wheat, or rye, the laſt of which is beſt.

If the mare has but little milk, boil as much as you can get from her, with the leaves of lavender and ſpike, and bathe the udder with it warm, till the knobs and knots are diſſolved. She ſhould now drink only white water (which is bran put into water;) give her alſo ſweet maſhes: and a month after foaling, let her have a maſh with ſome brimſtone or ſavin in it.

MARLE, a kind of dry, ſoft, foſſile earth, uſed in manuring land.

Marle is either grey, blue, brown, yellow, red, or mixed, and is known by its pure and uncompounded nature: beſides which, it is diſtinguiſhed by ſeveral other marks, ſuch as, its breaking into little ſquare bits: its faling eaſily to peices, by the force of a blow, or upon being expoſed to the ſun or froſt; its feeling fat and unctuous; and its looking, when dry, after having been expoſed to the weather for ſome time, as if it was covered with a hoar-froſt, or ſprinkled with fine ſalt. Even when mixed with the land intended to be manured by it, the whole ſurface of the ſoil will have that whitiſh appearance. But the moſt unerring way to judge of marle, and know it from any other ſuſtance that may reſemble it, is, to break a piece as big as a large nutmeg, and, when it is quite dry, drop it into a glaſs of clear water, where, if it be the right ſort, it will ſoon diſſolve into a ſoft and almoſt impalpable pap, ſhooting up many ſparkles to the ſurface of the water. Some marles effervеſce but little with acids: but they ſhould always be put to that trial; becauſe the more they effervеſce with them, the more valuable they are as manures. In hot weather, good marle will ſlake with the heat of the ſun, like lime; eſpecially if any rain follows a hot-day.

The farmers in Staffordſhire reckon the ſoft blue marle, which is moſt commonly found under clay, or low black ground, at the depth of ſeven or eight feet, the beſt for arable land, and the grey ſort the beſt for paſture. That which is of a browniſh colour. with blue veins in it, and little lumps of chalk or lime-ſtone, generally lying under ſtiff clays, and very hard to dig, is moſt eſteemed in Cheſhire. The marle which is uſually found at the depth of about two feet, or a yard, on the ſides of hills, and in wet boggy grounds which have a light ſand in them, is very fat and cloſe, and reckoned the ſtrongeſt of all marles; for which reaſon it is particularly good for ſandy lands. This is commonly called peat-marle, or delving-marle. The paper-marle, as it is ſometimes called, frequently lies near coals, and flakes like leaves or pieces of brown paper, than which it is of a ſomewhat lighter colour. That which ſome writers call clay-marle, becauſe it looks like clay, is very fat, and ſometimes mixed with chalk-ſtones. Steel-marle breaks of itielf into ſquare cubical bits. Theſe two laſt kinds generally lie under ſand or clay; ſometimes about a yard deep under the former, but often much deeper under the latter.

Stone, ſlate, or flag-marle, which is a kind of ſoft ſtone or rather ſlate, of a blueiſh colour, is generally allowed to be the beſt. It eaſily diſſolves with froſt or rain, is found near rives and on the ſides of hills, and is a very laſting manure. An ingenious gentleman, paſſing lately through Bedfordſhire, obſerved, that the people employed to mend the highways, were laying upon them a blueiſh kind of ſtone. Struck with the novelty of the appearance, he ſtopt, took up a lump, and ſoon found it to be this blue marle, which the ignorant peaſants were uſing inſtead of real ſtone. The conſequence was, that, when he returned the ſame way ſome time after, a heavy ſhower having fallen, the whole road where this ſubſtance had been ſo injudiciouſly ſpread, was become a perfect quagmire.

Mr. Markham reckons four ſorts of marle, in Suſſex; viz. grey, blue, yellow, and red. The blue is accounted the beſt, the yellow next, and then the grey. The red is

the leaſt durable. A great deal of the marle in the north country runs much upon the loam; but that in Suſſex is more like fuller's earth, and therefore muſt certainly be the fatteſt.

Mr. Mortimer ſays, he ſaw a ſample of marle from Derbyſhire, which was very fat, though it contained ſo much ſand, that, when wet, it could not be worked into a ball, or be made to hold together. This marle did very well upon clayey land, becauſe it was of an opening quality.

In many parts of moſt counties in England, marle diſcovers itſelf to the moſt negligent eye; particularly on the ſides of broken hills, or deep, hollow roads. Many rivers are bordered with a vaſt treaſure, which is plundered by every flood. Boggy lands frequently cover it; and, in them, it ſeldom lies above three feet deep. It is ſomewhat lower under ſtiff clays, and marſhy level grounds. The loweſt parts of moſt ſandy lands abound with it, ſometimes at the depth of three feet, and ſometimes at ſeven, nine, or more. The depth of the marle itſelf can ſeldom be found; for when the upper cruſt of the earth is removed, all that can be ſeen, or dug, is marle, to ſo great a depth, that there are few, if any, inſtances of a marle-pit's having been exhauſted.

Nothing is more common than to find the ditches which incloſe a field, dug ſo deep that they have penetrated ſix or ſeven inches into a bed of marle, without the farmer's taking any notice of it; though the extraordinary ſhooting and encreaſe of the graſs which is put forth by the marle thrown up on the ſides of the bank, might, one would think, be a means of diſcovering it. Where the marle is thus accidentally diſcloſed, it not only turfs the ſides and tops of the banks, and thereby ſecures them againſt all injuries of the weather, but makes the graſs grow ſo long and thick, that, when beaten down by winds, it hangs as if it thatched the earth which nouriſhed it, and carries off the rain, without letting any great quantity penetrate through it.

The marquis of Turbilly, in his excellent directions for clearing and breaking up land, recommends, for boring it (in order to know what different layers of earth, ores, quarries, ſprings, &c. lie underneath, and at what depth, by which means the better judgment may be formed of the plants moſt proper for the ſoil), an inſtrument of his own inventing, as far ſuperior to any thing that has yet been thought of for that purpoſe. A deſcription of it may be of ſervice to every ingenious improver of land. *See the article* BORER.

Marle is very common in Ireland, where it ſeldom lies above a foot or two below the ſurface of the ſoil; luckily for that country, which is extremely boggy. But in France, though they have marle in many places, they are often obliged to dig for it very deep, particularly in the province of Artois, where it generally lies eighty or ninety feet under ground, in beds about five feet thick, at the bottom of which frequently is water, which breaks in upon the workmen. On account of this great depth of the marle-pits there, extraordinary care is taken to ſet up marks, and rail them in, to prevent the fatal accidents which might otherwiſe happen. The ſame is, indeed, done in England; but not ſo ſtrictly as it ought to be.

Authors differ widely both as to the quantity and the manner of uſing almoſt all the manures they treat of; points which muſt, in a very great meaſure, depend on the quality of the ſoil, and the ſtrength of the manure, of whatever kind it be, and in which experience will ever be the judicious farmer's ſureſt guide. In marling, it is particularly neceſſary to find the true proportion which the land requires, and better to err in laying on too little, than too much; becauſe, more may be added at pleaſure; whereas by over-doing it, the firſt year's crop often fails, becauſe the body of the marle has not been ſufficiently opened; and, in that caſe, it will ſometimes be two or three years before the ground comes to a proper temper. The beſt directions that can be given to the farmer in the application of this manure to light ſoils, is, to lay on the quantity which will give the degree of coheſion wanted in thoſe ſoils. A general rule cannot be laid down in this reſpect; becauſe, the quantity of marle requiſite to effect the deſired end, muſt be different, in proportion to the degree of lightneſs of the ſoil.

Pliny ſpeaks of marle as a ſpecies of improvement known to the Greeks, but more peculiar to Britain and Gaul. He calls it, the fat of the earth, and compares it to the glands in the human body, which are lapped in a coat of fat. As this manure, ſo far as we can find, was not uſed, and probably not to be found, in Italy, it ſhews how attentive the Romans were to agriculture, wherever they carried their victorious arms; ſince, notwithſtanding the continual alarms they lived in from the natives here and in Gaul, they found time to diſcover and perfect a means of improving land, particularly ſuited to the ſoil and climate, and, of all others, the cheapeſt and moſt laſting.

Before we quit this ſubject, we muſt obſerve, with Dr. Home, that a body very ſimilar to marle in its appearance, but eſſentially different in its effects, is often found in the ſame bed with the beſt marle. It is of a darkiſh red colour. Inſtead of fertilizing the earth, it renders even the beſt ſoils incapable of bearing any kind of vegetables for many after. I have ſeen, ſays that gentleman, the ſpots on which it was laid, entirely barren three years after; and have heard of its bad effects continuing in other places for a much longer time; nor is it certain when they will ceaſe. A body ſo very deſtructive to agriculture, deſerves to be well characterized, in order to its being ſhunned; and ſhould be thoroughly examined, that we may know whence proceeds this noxious quality, and how to cure it when it has taken place.

Marle takes a ſmooth poliſh from the inſtrument with which it is wrought. A piece of this taken up, when it has not been much expoſed to the influence of the air, differs greatly in taſte from marle. Inſtead of the ſmooth unctous taſte of the latter, it is acid, and remarkably aſtringent. It agrees with marle, in crumbling in water but differs remarkably from it in not raiſing any effervеſcence with acids, nor in the leaſt deſtroying their acidity. It turns the ſyrup of violets red; which ſhews that it contains an acid: whereas marle, like all abſorbent earth, gives it a green colour. The trying of marle with acids is therefore the more neceſſary, to guard againſt uſing this pernicious ſubſtance.

It appears from experiments made by the doctor, that this pernicious ſubſtance conſiſts of an earthy body like clay, about an eighteenth part of ſalt of ſteel, and a ſmall proportion of the vitriolic acid; from whence he concludes, that good marle is the proper cure where this noxious earth has been inadvertently uſed; becauſe it corrects the acid, and decompoſes the ſalt.

The

The following account of marle was ſent by a very intelligent gentleman to the editors of the *Muſeum Ruſticum*.

A ſhort Diſſertation on Marle.

It is taken out of the bowels of the earth at ſeveral depths, is of divers colours as after named, and ſome ſorts have often two or three colours intermixed. It is unctuous, of a ſlippery nature, and in goodneſs pure; ſoon relents after rain, and, when dry, ſlackens like lime, and at laſt diſſolves into the fineſt powder.

I intend to leave with you ſome ſpecimens of two kinds of marle (which you may give to the gentlemen or farmers who deſire them): they are what I have collected in Middleſex, which county abounds with good marle; but it is not uſed by the gentry, or farmers, ſo much as it ought, becauſe they have ſo readily dung, ſoot, aſhes, and other compoſts, from London.

In order to diſcover marle, the beſt way is to uſe the auger, and obſerve the ſtrata taken up from time to time by it.

I have found, after I have got through the ſurface, which is about a ſpade and half deep, that the next earth was a very ſtrong, coarſe, bed of clay, five or ſix feet deep; afterwards, getting through it, the auger brought up marle, viz. that which appears of a fine light-brown colour, and ſome of it mixed with blue veins (which I will here call pigeon marle, by way of diſtinction): here was a bed of this pigeon marle of five or ſix feet deep, and after that followed another kind of marle, which I will call toad marle, by way of diſtinction; this is heavier, and without any veins of blue.

When either of theſe marles are dug out of the pit, the ſpade cuts them like ſo much ſoap; and the laſt-named marle look very blackiſh and dark, and may be, and I believe is, in ſome countries, called toad marle, from its reſemblance in colour to that animal; but this marle being expoſed to the air alters the colour very much. This appears to me to be the ſtrongeſt marle.

Marles may be diſcovered ſometimes near the ſurface, by carefully obſerving the ditches and fences of your lands.

It is frequently found near rivers, or brooks, and ſometimes may be diſcovered on the banks of ſuch waters.

To know when you have found true Marle, try it by Air, Fire, and Water, or Vinegar.

Firſt, By expoſing a large lump of three or four pounds in the air, which, if true marle, will, in a little time, by the nitre, dews, &c. break into ſmall parts; and there will be an hoary, or white, congelation on that part of it which is expoſed to the ſun.

Secondly, When your marle is dry, break it into ſmall particles, and put an handful into an hot coal fire, and it will crackle as if ſo much ſalt had been put therein.

Thirdly, Place a piece of the dried marle in a glaſs, and thereon gently pour as much water as will cover it. If true marle, it will then gradually moulder, and diſſolve into a liquid ſoap. Let not the glaſs be ſhaken, that you may obſerve the ebullition (which is material); or you may, in like manner, try it with vinegar, where the effervеſcence, or ſtruggling, will be much ſtronger than in water.

The Virtues of Marle.

It is the beſt manure for ſandy, dry, gravelly, or light lands of any kind: It is excellent for moſſy lands. It is, indeed, good for all other lands, of what nature ſoever, even clay, provided care be taken in laying on a proper quantity, and that the ſame be well diſſolved.

Care muſt be taken in the quantity uſed; if too little, you may eaſily add; but if too much is laid on the land, you cannot take it away.

It is uſed in ſome countries for arable lands only: yet it is as good for graſs or paſture lands, but does not the firſt, and ſeldom till the ſecond year, ſhew forth its utility; and then you will obſerve the graſs to ſhoot out a dark, or blackiſh colour, which afterwards turns to the fineſt green; and with it come up quantities of white clover-graſs, which hath occaſioned me ſome difficulty with the farmers to convince them I had not ſown the clover-ſeed.

If lands are properly marled, they will continue good for twelve or fourteen years for the plough; and for paſture, or graſs-lands, much longer.

I would recommend that the plough be not ſuffered to enter into the land till the marle is thoroughly diſſolved.

Fiſh thrive prodigiouſly, and grow fatter in marle-pits than any other ponds.

Quantities to be uſed.

A great difficulty this to aſcertain the quantity.

In ſome countries they will tell you of laying three hundred loads to an acre, others more, others leſs; but they no where aſcertain what is a load. In Cheſhire and Lancaſhire their loads are ſcarcely ſix buſhels, and they uſe a ſmall cart made for the purpoſe, drawn by two or three ſmall horſes.

If the land is gravelly, ſandy, or light, let as much be laid on it as will make a good thick coat to bind and ſtiffen the ſoil.

But let the land be what it will, ſo much ſhould, in all events, be laid on as will make a thin coat over the entire ſurface.

Upon my lands, which are graſs and paſture, of a tolerable mould, on a clayey ſoil, and which were left, about eight years ſince, in a bad plight, by the late tenant, I firſt attempted to lay ten loads to every acre, (by a load I mean as much as three large, well-fed, ſtrong horſes could draw) but found it was too little, and would not meet in the ſpreading.

I immediately doubled the quantity, and two years afterwards I added another coat of fifteen loads more to every acre, and find it anſwers very well for hay and paſture. I need not ſay horſes and cows are fonder of this hay and graſs than of that wherein the dung may be taſted and ſmelt.

A work of this kind ſhould be ſet about by the end of Auguſt, or beginning of September; and the loads ſhould be ſhot into ſmall heaps, as the Middleſex farmers ſhoot their dung, viz. two or three buſhels in each heap; and a man muſt be ready to ſeparate it, that the nitre, air, dews, and rain, coming on the large pieces, may act, and cauſe them to break, as of themſelves, into ſmaller parts.

After the marle has been laid upon the ground, and you ſee that the air, nitre, &c. have looſened the great lumps,

and

and they are ready, on a ſlight touch, to fall into pieces, a perſon ſhould be ordered (when the weather and marle are quite dry) to break and ſpread the pieces to complete your coat; and you ſhould avoid as much as poſſible, leaving any large pieces to lie and diſſolve without being ſpread on the ſurface, but cauſe them to unite therewith.

In the beginning of February, and in dry weather, I cauſe an old gate to be well buſhed, and a heavy weight laid on it, to be drawn by one horſe over the whole field, in order that every part may have its due proportion.

If you intend to plough your lands, the preceding cautions are not ſo neceſſary, as the plough and harrows will ſpread and intermix the marle with the ſoil ſufficiently; but if you uſe the drill-plough, the above hints may be uſeful.

It would take a volume to give an exact and full hiſtory of marle, its virtues and uſes, and to ſhew that it was uſed by the Romans, and many years diſcontinued, and eſpecially till the houſes of York and Lancaſter were united, and then revived in ſome few counties; and the great benefits received by marling in Suffolk and Norfolk within a few years paſt.

We very well know that gentlemen and farmers are a long while ere they care to venture on the practice of marling from theory, and principally from not having ſeen or known what is, and what is not, true and genuine marle, and from being unacquainted with the rules or modes to judge and determine upon it: therefore, if this ſhort account will obviate their doubts, and in any way contribute to the advancement of agriculture, vegetation, and paſturage, my deſign is anſwered.

There are variety of colours in marle, viz. blue, white, yellow, red, and other colours, which make no material difference, provided they be earthy and fat, or ſlippery as ſoap, and as free as poſſible from a mixture of ſand, gravel, or ſtone.

DICE MARLE, a name given by the people of Staffordſhire to a reddiſh marle, that breaks into ſmall ſquare pieces like dice, or into thin flakes, in the manner of lead ore, and looks ſmooth on the ſurface.

MARSHY LANDS, a ſort of paſture or grazing grounds, lying near the ſea, rivers, or fens.

As to lands lying near rivers, the great improvement of them is their being overflowed, which brings the ſoil of the uplands upon them, ſo that they need no other mending, though kept conſtantly mowed. The great inconveniency of theſe lands is their being ſubject to floods, which high hills near the ſides of rivers, and the long courſe of them, beſpeak to be frequent: and, though the richeſt land generally lies near ſuch rivers, yet there is the greateſt danger of the crops being ſpoiled, eſpecially when they are not incloſed, and therefore cannot be fed with cattle. This, when feeding bears any thing of a price, would be the very beſt way of managing theſe uncertain lands; and incloſing them would be highly beneficial on this account. *Mortimer's Huſbandry.*

The marſh-lands in Lincolnſhire, and many other parts of England, produce a ſort of graſs, which feed ſheep in a better manner than that of almoſt any other land, in regard to their ſize, and the quantity of wool. The ſheep about Grimſby, and ſome other places in this county, produce ſuch luſty wool, or, as they call it, wool of ſo large a ſtaple, that three or four fleeces uſually make a tod of twenty-eight pounds weight. Several hundred loads of this wool are yearly carried from theſe places to Norfolk, Suffolk, and other parts of the kingdom, for the cloth manufacturers. They ſend this in large packs, which they call pockets, each containing about five and twenty hundred weight. *Philoſ. Tranſ.* Numb. 223.

When marſh lands lie flat, it is neceſſary for the owner to keep all the water he can from them. The ſea-water in particular is to be kept from them as much as poſſible; and this is uſually done at a very great expence, by high banks and walls.

Two things greatly wanting in theſe lands, in general, are good ſhelter for the cattle, and freſh water. The careful farmer may, however, in a great meaſure obviate theſe by digging in proper places, large ponds to receive the rain water, and by planting trees and hedges in certain places towards the ſea, where they may not only afford ſhelter for the cattle, but keep off the ſea breezes, which often will cut off the tops of all the graſs in theſe places, and make it look as if mowed.

Theſe lands fatten cattle the ſooneſt of any, and they preſerve ſheep from the rot. It would be of great advantage to them, if there were raiſed, in the middle of every large marſh, banks of earth in a croſs, or in the form of two ſemi-circles, and theſe planted with trees; theſe would ſerve as a ſhelter for cattle, let the wind blow from what quarter it would, and would ſoon repay the expence of making.

There are, in different parts of England, very large quantities of land upon the ſea-coaſts that would be worth taking in, though no one has yet thought of doing it. The coaſts about Boſton, Spalding, and many other parts of Lincolnſhire, give frequent inſtances of this, where the ſea falls from the land, ſo that on the outſide of the ſea walls, on the owſe, where every tide the ſalt water comes, there grows a great deal of good graſs, and the owſe is firm to ride upon when the water is upon it.

This owſe, when taken in, hardly ſinks any thing at all, and they dig the walls from the outſide of it, all the earth they are made of being taken from thence, and the ſea, in a few tides, filling it up again: and though the ſea, at high water, comes only to the foot of the bank, yet once in a year or two, ſome extraordinary tides go over the banks, though they are ten feet high. Theſe banks are fifty feet broad at the bottom, and three feet at the top; and the common price of making them is three ſhillings a pole, the earth being all carried in wheel-barrows, and face towards the ſea, where the greateſt ſlope is, being turfed. *Mortimer's Huſbandry.*

MATFELLON. *See* BLUE BOTTLE.

MAY-WEED, a wild ſpecies of chamomile, a trailing perennial plant, which puts outs roots from its branches as they lie on the ground. By this means, and by ſcatterings its ſeeds long before the corn is ripe, it ſpreads and multiplies greatly. It flowers in May, and thence has acquired the name of May-weed.

The means of extirpating it are, ſummer fallows, repeated good harrowing, and burning the collected roots, as before directed, in ſimilar caſes, or, which will be found ſtill more effectual, the frequent hoeings practiſed the New Huſbandry. What eſcapes theſe clearings ſhould be very carefully pulled up by hand; for the common weeding-hook will not go deep enough to take out the whole of the long ſlender tap root of this plant, of which every remaining bit that has a knot in it will produce new ſhoots. Nor ought the farmer to regret this ſmall additional expence, to get rid of one of the moſt

fatal enemies his corn can have. Mr. Liſle aſſures us, that as good a crop of wheat as one would wiſh to ſee all the winter time was, to his knowledge, ſo deſtroyed by the coming up of May-weeds and poppies in the ſpring and ſummer, that it did not at laſt yield ſo much as the ſeed.

MEAD, a liquor made of honey, and held in great eſtimation by moſt of the northern nations, but perhaps not eſteemed here ſo much as it might deſerve, if due care was taken to prepare it properly.

All the writers who have hitherto treated of this ſubject, have given into a capital error with regard to the ſtrength of this liquor, by directing too great a proportion of honey to be diſſolved in the water. The uſual practice of making it ſo ſtrong to bear an egg, is very wrong. The liquor is thereby rendered a meer ſtum, and this bad quality is ſtill increaſed by the long boiling generally practiſed. It is ſcarcely poſſible to procure honey ſo pure, but that ſome bee-bread, wax, or other ſubſtance, is mixed with it; and this cannot be perfectly ſeparated from it, ſo far as I know, but by boiling. On this account the boiling of mead ſeems indiſputably neceſſary. In order the more effectually to ſeparate theſe impurities from the liquor, it will be adviſable to mix ſome whites of eggs with it before it is put on the fire, and it will be particularly neceſſary to ſkim off the thick ſcum that riſes, the moment the liquor begins to boil; and this muſt be attentively continued ſo long as it boils. The only intention of boiling being here to ſeparate the impurities, and to make a perfect union of the water and the honey, both which purpoſes are very ſoon obtained, it evidently appears, that the boiling need be of but very ſhort duration. This becomes here more particularly neceſſary, becauſe the liquor will be the leſs diſpoſed to ferment kindly, the longer the boiling has been continued. It is perhaps owing to the ſingle article of long boiling, that mead has hitherto lain under ſo great diſcredit; becauſe it then never fermented ſufficiently to take off its luſcious ſweetneſs; whereas, had it undergone a due fermentation, that ſweetneſs would have gone off, and the mead would have attained a fine racy flavour.

Some notable houſewives have added hops to their mead. This helps to take off its ſweetneſs, and, as the bitterneſs of the hop goes off, gives it a pleaſant flavour. A ferment is here, as in all liquors that are boiled, generally wanted to bring on a perfect fermentation: but as the leaſt taint in the ferment is communicated to the whole liquor, particular care ſhould be taken that it be very ſweet and good. Mead, judiciouſly managed on theſe principles, will keep for years, and be improved by age. The racking, fining, &c. of this liquor, are the ſame as thoſe of other white wines.

MEADOW, a general name for paſture or graſs-lands, annually mown for hay; but is more particularly applied to lands which are ſo low as to be too moiſt for cattle to graze upon them in winter, without breaking the ſward.

Meadows, being generally enriched with the fine mould waſhed down from the adjacent riſing grounds, are uſually of a good ſoil, and ſeldom require any other improvement, than the removing of temporary imperfections. But they may likewiſe be of ſuch a nature as to ſtand in need of a more particular treatment: as is the caſe when their ſurface is a moſſy looſe earth, or when it is of a binding or clayey quality.

If, through long neglect, a coarſe ſtrong graſs, ruſhes, or other buſhy plants, be ſuffered to remain upon the ground till they rot there, they will, in ſome years, form a looſe ſpongy ſubſtance, ſomewhat reſembling moſs. In this caſe, the firſt neceſſary ſtep is to pare off and burn that looſe ſurface, or at leaſt ſo much of it as to enable the plough afterwards to reach the better ſoil underneath. The manner of doing this has already been explained ſo very amply, that it will be ſufficient to add here, that this looſe upper earth muſt be ſo ſtrengthened as to afford ſufficient ſtability to the roots of whatever plants are ſown on it, by mixing it well, either with the better ſoil underneath, or with marle, clay, or rich loam, brought to it from the neighbouring grounds, or with the compoſts before directed for this purpoſe.

If the ſoil is clay, or a ſtrong binding earth, the treatment of it is much the ſame, whether it be meadow or upland paſture. Such ſoils, by retaining water in every hollow place, become what the farmers call ſour, and produce a coarſe graſs, compoſed, as Mr. Miller obſerves, of bad weeds, of which the ſeveral ſorts of docks make no ſmall ſhare. Although many of the meadows produce a great burden of what the country people call hay, yet this is fit only for ſuch cattle as, by hard labour and hunger, are driven to eat it: for horſes which have been accuſtomed to feed on good hay, will almoſt ſtarve rather than touch this. A plain proof of its being diſagreeable to all cattle, is, that when they are turned in, after it has been mowed, we often ſee the ground covered with rank weeds, which they will not meddle with.

When a paſture is in the ſtate above deſcribed, if there is a ſufficient depth of ſoil to admit of it, the ſurface ſhould be pared off, and burnt: and as ſuch places are uſually over-run with ant-hills, theſe ſhould alſo be burnt; after which, by the addition of proper manure, and by the help of deep plowing, the land ſhould be brought into fine tilth. The deeper this improvement goes, the deeper and more laſting will the graſs be. We have been informed of a particular inſtance of the good effects of this method, by which the gentlemen who practiſed it had graſs which continued for years in a ſtrong ſtate of vegetation, and was conſtantly near a month forwarder than that of his neighbours, whoſe ſoil and ſituation were exactly the ſame.

Let not any one be deterred by the expence attending this improvement: for the crops of grain and other plants taken while the ſoil is thus preparing, will nearly repay all the charges, and the ground will afterwards yield much more plentiful crops of graſs; at leaſt for a number of years. But as clayey lands require more frequent and more thorough repairs than other ſoils, the returns of tillage propoſed by Camillo Tarello will be the moſt proper means of managing them.

He would have farmers divide their paſtures in four parts, keep one of theſe parts under grain or pulſe, during five years, and at the expiration of that time lay it down to graſs as before; and ſo proceed with every other part. He propoſes, that the firſt breaking up ſhould be by paring and burning, and thorough plowing. But if we may differ from him in opinion, we think it is needleſs to keep the ground ſo many years in tillage, unleſs this ſhould ſuit the huſbandman's convenience for the culture of particular plants. In this caſe, the paſture may be divided into five or ſix parts. After each part has thus been in tillage, Tarello adviſes breaking up again the ſpot firſt began with; though

though not by burning now, but only by ploughing, in order to ſow it as before. "This, ſays he, will be profitable to the huſbandman, and improve the paſture. It will benefit the huſbandman, becauſe he will thereby raiſe a greater quantity of corn; and it will do good to the paſtures, becauſe nothing is more ſerviceable to them, than this renewal of their ſurface, as is atteſted by Columella. Let not the huſbandman imagine that he will have leſs hay when only three fourths of his uſual extent of land are under graſs: for, in fact, it is not the quantity of the land, but the care which is taken of it, that gives plenty of hay."

When a ſoil of this kind is laid down for meadow, great care ſhould be taken to ſlope it down gently, from the middle, in ſuch manner that no water may reſt on any part of it. If the extent is large, ſmall ditches ſhould interſect the meadow into as many diviſions as ſhall be neceſſary to form a ſufficient drain for the waſte water, and the ſpaces between theſe ditches may be gently raiſed. In an upland paſture on ſuch a ſoil, ridges ſhould be raiſed inclining a little from the horizontal, that the furrows may be ſo many drains, as before directed in the ploughing of ſuch ſoils, to prevent their becoming ſpewy or wet: for as the rain cannot deſcend beyond the clay, it will glide along it, till, collected in ſuch quantities as to form a ſmall ſtream, it iſſues forth at the ſurface, uſually loaded with ſome mineral quality imbibed from the earth underneath.

When the ſoil is a rich or light loam, the plough will not be ſo neceſſary; as ſuch meadows or paſtures may be repaired by the means which will be pointed out in the directions hereafter given for the improvement of the meadows already laid down to graſs. *See the article* GRASS *and* PASTURE.

Black, rich mould, requires but a moderate quantity of water: juſt ſufficient to give action to the fertilizing particles it contains. The watering here ſhould be frequently repeated, rather than long continued.

It is a general rule, that ſandy or gravelly ſoils require watering the moſt of any; becauſe whatever moiſture they receive, ſinks through them too ſpeedily. But it may be doubted, whether this very reaſon for watering them be not one of the greateſt of objections againſt their being watered, at leaſt ſo much as is generally directed: for the water not only paſſes rapidly through theſe ſoils, but it may carry down with it through the ſand or gravel, the finer and richer particles of the ſhallow mould uſually found upon ſuch ſoils, and thereby rather impoveriſh their ſurface. It would therefore ſeem adviſable, to let water in upon ſuch ſoils only occaſionally, to refreſh their verdure, when their ſurface is too dry: and to give it a pretty quick current, that it may reach to a greater extent of ſurface: for if it runs ſlow, it ſinks too faſt.

It is a queſtion whether paſtures newly laid down to graſs, after having been arable land, ought to be watered at all during the firſt year. The judicious author of one of the ingenious diſſertations in the Memoirs of the Berne Society conſulted on this ſubject an intelligent farmer, who had experienced the effects of watering, and of not watering, theſe new paſtures, as ſome call them, and was anſwered; that they had yielded the greateſt quantity of graſs the firſt year, when they had been watered, but that the crops had always dwindled in the ſucceeding years: whereas thoſe that were left dry till autumn, and then only begun to be watered, had made ample amends during the following years, for the ſcantineſs of their produce in the firſt. This huſbandman was therefore of opinion, that it is beſt not to water theſe meadows before the autumn; and he added a farther very ſenſible reaſon, namely, that as theſe new meadows ſtill retain ſome portion of the manure laid upon the land the year before, when it was ſowed with corn; the letting in of water upon them, while the mould is yet extremely looſe and light, will be apt to carry off thoſe rich remains of manure, which will otherwiſe incorporate with the ſoil, as it acquires more conſiſtence.

A very wrong cuſtom which prevails among our farmers, in general, with reſpect to low meadows, is, that of flowing them during the whole winter. The roots of all the ſweeteſt kinds of graſſes are thereby deſtroyed, and only ſuch left as are natives of marſhes, which are coarſe and ſour, and which no cattle will eat.

The method which Mr. Miller propoſes for the management of theſe meadows, is never to flow them till the middle or latter end of March, excepting once or twice in the winter, when ſuch floods happen, as bring down a great deal of ſoil from the upper lands: for then it will be of great ſervice to let ſuch water in upon the meadows, that the ſoil may ſettle there: but the ſooner the wet is drained off after this is lodged, the greater will be the benefit done to the meadows. By letting on the water frequently, from the end of March to the middle of May, the growth of the graſs will be greatly aſſiſted, and there will not then be any danger of deſtroying its roots.

River water, which is univerſally acknowledged to be the beſt for this purpoſe, cannot be ſo beneficial when the ſtream overflows its banks, and runs rapidly over the paſtures, as when its courſe is ſlow; and ſtill much leſs than when it ſtagnates. It therefore is adviſable to fence in every meadow liable to be thus overflowed, in ſuch manner that it cannot be flooded, but at the owner's pleaſure, by opening proper ſluices. But as the produce of many meadows will not bear this expence, the proprietor, or farmer, ſhould, if poſſible, prevent the too haſty current of the water, by raiſing at their upper end, or wherever elſe it may be neceſſary, ſuch fences as ſhall render the water which flows ſidewiſe upon the meadow, rather a back, or ſtanding water. Great advantages will ariſe therefrom. The finer mould will no longer be carried away by the ſtrong current of the river, which, inſtead of robbing the ſoil, will then depoſit a rich ſediment, and thereby greatly fertilize the land.

The water of mineral ſprings ſhould not by any means be brought upon paſtures; becauſe they are either deſtructive of graſs, or produce only a very harſh coarſe kind of it.

We ſhall cloſe this ſubject with the following remarks made by the judicious author of one of the before-mentioned diſſertations in the Memoirs of the Berne Society, and which deſerve the ſerious attention of every huſbandman who would water his paſtures with due care.

"Many people imagine, that the whole art of watering meadows conſiſts in making good channels, and in opening and ſhutting the ſluices at proper times. But this is not enough: for ſo long as the water flows in a meadow, the farmer ſhould viſit all his channels once or twice a day, with a ſhovel, hoe, or three grained fork in his hand, and examine carefully whether any of them want cleanſing or repairing. Sometimes he will find a channel choaked with ſlime; in other places he will ſee the water ſpread too far, or not far enough; and in others again he will obſerve it not riſe high enough to overflow its channel, ſo that the neighbouring

neighbouring ground is not watered at all. He will immediately endeavour to remedy theſe defects, according to the exigency of the caſe, whether by clearing away the muddy ſlime, heightening the banks of the channel, lowering them, giving a freer current to the water in ſome places, and checking its courſe in others, according to the nature of the ſoil; or by cutting new channels in ſome places, and laying ſods or ſluices acroſs others, to divert the ſtream from ſuch parts as are ſufficiently moiſt, and turn it to others which want watering: for it frequently happens that, even in the ſame meadow, though not a large one, there are very different ſoils, each of which requires the aſſiſtance of water, but in different degrees. In ſhort, the careful huſbandman will not ever viſit his paſtures without noticing in them things which may be altered and amended."

The farmer who has improved his meadows according to the foregoing directions, may expect abundant recompence in plentiful crops of graſs.

When graſs is to be fed off, it ſhould not be permitted to ſtand till it grows high, becauſe the cattle will then trample under foot great part of it, which they afterwards will not eat. The prudent huſbandman will alſo vary the kinds of cattle fed upon it. *See the article* HAY.

MELILOT, a plant of the trefoil kind, and grows in ſuch abundance among the corn in many parts of England, particularly in Cambridgeſhire, as to be a moſt troubleſome weed; for it is hardly poſſible to ſeparate it from the corn in reaping, ſo that they are houſed together, and the ſeeds of the melilot, which ripen about the ſame time as the corn, are threſhed out with it, after which, they being likewiſe heavy, it is very difficult to ſeparate them. If but a few of theſe ſeeds are ground with the corn, they will ſpoil the flour; for the bread, or whatever elſe is made with it, will have a ſtrong taſte and ſmell like melilot plaiſter. The roots of this plant are ſtrong and woody, and from them ſpring out ſeveral ſtalks, which riſe from two to four feet high, according to the goodneſs of the land. Theſe ſtalks branch out, and are garniſhed with trifoliate leaves, having oval ſawed lobes of a deep green colour. The flowers are produced in long ſlender ſpikes, which ſpring from the wings of the ſtalks. They are of a bright yellow, ſhaped like the other butterfly flowers, and are ſucceeded by naked ſeeds, which ripen in Auguſt.

MESLIN-CORN, wheat and rye mixed together.

MET, a ſtrike, or four pecks.

METEYARD, or METERWARD, a ſtaff of a certain length for taking meaſures.

MIDDING, a dunghill.

MIDGE, a knat.

MILDEW, a diſtemper very deſtructive to corn.

"This diſtemper, ſays M. Duhamel, attacks the blades and ſtems of corn, which it covers with a powder of the colour of ruſt of iron, when at the height of their vegetation. This ſubſtance does not adhere ſtrongly to the blades; for I have ſeen the hair of white ſpaniels full of this powder, after they have run through a field attacked with this diſeaſe. It is likewiſe known, that if the infected wheat is waſhed by a plentiful rain, the ruſt diſappears almoſt entirely, and the grain ſuffers little from it. The French give it the name of ruſt, from the colour of the powder, and it ſeems to be the ſame diſtemper which the Roman writers call *rubigo*.

"The cauſe of this diſtemper is uſually imputed to dry gloomy weather, happening while the corn is at the heigh of its vegetation: and in effect I have many times obſerved, that when a hot ſun has ſucceeded ſuch dry hazy weather, the corn was ruſted within a few days after.

"This diſtemper is not common in clear and dry hot years: but when the ſpring is wet, the fineſt fields of wheat run great hazard of being deſtroyed by the mildew, which generally appears upon the breaking out of the ſun in the morning, after cloſe and ſultry weather, during which there has not been any dew. The ruſty powder then gathers upon the blades in ſuch quantities as to cover the earth two feet around. M. de Chateauvieux cut off the mildewed blades, and found the trial anſwer: the ſame plants produced new blades, and throve much better than thoſe on which this operation had not been performed: but this cannot be done except when the corn is very young.

"This diſtemper is very fatal: for the fineſt wheat is ſuddenly brought almoſt to nothing, when it is entirely attacked with it.

"If it attacks the plants while they are young, and before their ſtems begin to riſe, the miſchief is ſometimes not very great, provided there comes on a ſeaſon favourable to their farther growth. In this caſe, they are only weakened, as if they had been fed or mowed. They ſhoot out anew, and produce ears: though their ſtraw is ſhorter, and thoſe ears are ſmaller, than they would otherwiſe have been. But if both blades and ſtalks are mildewed at the ſame time, the farther growth of the plant is ſtopt, and the grain gets ſcarce any more nouriſhment; ſo that the crop is exceedingly diminiſhed.

"This grievous diſtemper well deſerves the ſerious attention of every inquirer into nature, who intereſts himſelf in the progreſs of agriculture; and I cannot too ſtrongly exhort all ſuch to endeavour to inveſtigate its cauſes and remedies.

"Several authors have, very improperly, confounded this diſtemper with others to which corn is ſubject. M. Tillet imputes it to a ſharpneſs in the air in dry cloudy weather, which breaks the veſſels interwoven with the ſubſtance of the blades and ſtem, and makes them diſcharge a thick oily juice, which, drying by degrees, is turned into that ruſty powder. In effect, if we examine with a microſcope, or only wirh a good magnifying-glaſs, plants of wheat, whoſe ſtems and leaves are covered with ruſt, we ſhall ſee diſtinctly ſmall crevices in the places where this powder lies, and ſhall diſcern, from ſpace to ſpace, in the membrane of the plant, openings through which it ſeems probable that the juices, afterwards converted into this ruſty powder, iſſues, and over which one may perceive ſome ſlight fragments of the membrane imperfectly covering thoſe cracks and openings.

"In ſupport of this opinion, M. Tillet quotes a memoir of M. de Renéaume, publiſhed in the Tranſactions of the Academy of Sciences, on the extravaſation of the nutritive juice of the walnut trees in Dauphiny: of the manna of Calabria, which is not a dew, but the extravaſated juice of the leaves of a kind of aſh; and what M. Muſchenbroek relates in his Phyſical Eſſays of thick and oily juices which iſſue out at the excretory veſſels of leaves, and ſtop there in the conſiſtence of honey.

"However this may be, the ruſt of corn is the conſequence of a diſtemper of which the firſt cauſe is not yet ſufficiently known. It is a miſtake to think, that the ruſt and mealy powder which may be ſeen on many plants are a collection of eggs laid there by inſects, and that this is a

ſource of other innumerable inſects very fatal to vegetables. By admitting the extravaſation of the nutritive juices, as the cauſe of theſe diſtempers, we ſhall conceive that the ruſt of corn, the honey-dew, the mealy-dew, and all the unctuous ſubſtances which are found upon gramineous plants, depend on the quality of the juice concentrated in the plants, upon the outſide of which it manifeſts itſelf by evaporation, and is converted ſometimes into an impalpable powder, and ſometimes into that thick ſubſtance which is red on garden-beans, of a ruſty colour on all kinds of corn, greeniſh on the plum-tree, yellowiſh on the aſh, white on the larch-tree, &c.

"Theſe obſervations and reflections ſtill leave undoubtedly much room to wiſh for farther information. They will, however, help to point out the path to a careful obſerver, and ought to excite philoſophers to exert themſelves in a matter of ſo great importance to the public. We confeſs that we have tried to produce the ſame effects as the dry hazy weather, which occaſions the ruſt, by applying to the leaves of many plants, acid and corroſive liquors, to others alkaline or ſpirituous, and frequently ſuch clammy glutinous ſubſtances as might ſtop the perſpiration without hurting the texture of the plants: but none of theſe trials have produced any thing like ruſt. However, who can tell how far experiments may lead the judicious and attentive? Some little circumſtances which may have eſcaped us, might perhaps, if duly remarked, have led us to the object of our ſearch. The public welfare calls on all attentive obſervers, to exert themſelves on this very intereſting ſubject.

"Count Ginanni, in a memoir printed in the *Journal Economique*, for October 1761, treats expreſsly of this diſtemper, and ſays, he has obſerved, with the help of a microſcope, ſmall worms lodged between the two membranes of the blades.

"If we had any certain knowledge of the cauſes of the ruſt, we ſhould probably be enabled the more eaſily to find preſervatives againſt it: but in the mean time it will be right to collect every obſervation made by lovers of agriculture; becauſe they will certainly afford uſeful lights at one time or other.

"M. de Chateauvieux obſerved, in the autumns of 1753 and 1754, that when the corn was ruſted, the ſecond crop of hay was ſo likewiſe. The graſs turned from a fine green, to the ugly ruſty colour of the corn: it was covered with the ſame kind of powder, and its quantity diminiſhed ſenſibly every day; and as the whole of a field of corn is not uſually affected at the ſame time, ſo this diſtemper extended only to ſome parts of the meadow.

"The cauſe of this diſtemper is undoubtedly the ſame in corn and in graſs; but its effect is not exactly ſimilar. It may deſtroy annual plants, ſuch as corn, entirely; but in perennials, like graſs, it deſtroys only the leaves or blades. May not the preſervation of theſe laſt be owing to the taking off of thoſe leaves or blades, when they are cut for hay? But this is only conjecture; for I own that I have not yet made any obſervation on this head.

"As the ſtraw of ſmutty, mildewed, or ruſted corn, and by the ſame rule graſs, in a ſimilar condition, may poſſibly give diſeaſes to cattle fed with it; it were to be wiſhed, for the public good, that a parcel of fodder, the moſt infected with either of theſe diſtempers, ſhould be ſet apart for the food of a certain number of beaſts. If cows or oxen, for example, remain ſound and healthy after having been fed with this growth for two or three months, we may afterwards give it them with confidence and ſafety: but if, on the contrary, they are viſibly diſordered by it, the remedy is eaſy and at hand, by feeding them with good wholeſome hay, which will carry off the diſeaſe, then known to proceed from the bad quality of the food."

The air in England ſeldom is ſo dry as to exhale all the moiſture of the glutinous exſudations, and thereby convert them into the ruſty powder above deſcribed. The extravaſation of the ſap ſeems to account for this diſtemper of plants in a much more rational manner, than the thick clammy dews which ſome of our authors ſpeak of, as falling in cloſe weather, ſtopping the perſpiration of vegetables, and hindering their juices from aſcending to nouriſh the flowers, &c.

Mr. Miller takes the true cauſe of the mildew's appearing moſt upon plants which are expoſed to the eaſt, to proceed from a dry temperature in the air when the wind blows from that point; in which caſe it ſtops the pores of plants, and prevents their perſpiration, whereby their juices are concreted upon the ſurface of their leaves; and that concretion being of a ſweetiſh nature, inſects are incited thereto. Thoſe inſects, finding their proper nutriment, depoſit their eggs, and multiply ſo faſt as to cover the whole ſurfaces of plants, and, by corroding their veſſels, prevent the motions of the ſap. He thinks it very probable, that the excrements of theſe inſects may enter the veſſels of plants; and, by mixing with their juices, may ſpread the infection all over them; for it is obſervable, that whenever a tree has been greatly infected by this mildew, it ſeldom recovers in two or three years, and many times never is entirely clear from it after. But he by no means allows theſe inſects to be the firſt cauſe of this diſtemper, as ſome have miſtakenly imagined.

It is obſervable, that mildews and blights frequently attack only one ſort of corn, or fruit, and leave the other ſpecies unhurt.

Count Ginanni diſtinguiſhes two principal kinds of mildew, one of which ſpots the blades and ſtems of corn, and dries upon them, without ever producing any powder; but penetrates through their outward covering, and entirely dries them up. This is generally of a pale colour, either reddiſh, yellowiſh, purpliſh, or blackiſh; and ſometimes a variegated mixture of many colours. The other ſpeedily covers the plant with a moiſt and thickiſh ſubſtance, which afterwards becomes dry, and turns into a powder, of one or other of the abovementioned colours, but moſt commonly reddiſh or yellowiſh. This, ſays he, always fades, corrodes, and ſeparates the outer ſkin from the plant. The former extends to every ſpecies of corn; but the latter is almoſt peculiar to wheat in the blade; though it is ſometimes ſeen upon oats and barley. Some may perhaps reckon, as a third ſpecies of mildew, a yellowiſh ſubſtance, or powder, ſometimes ſeen under the membrane of the blades of corn, where it raiſes bliſters, makes many little holes and cracks, and corrodes the fibres; and perhaps they may not be wrong in accounting it ſuch.

He is confident that this diſtemper is the rubigo of the Latins.

"For the vegetation of ſeeds," continues count Ginanni, "after they have been properly depoſited in the earth, for their fecundity, their ſprouting, and the increaſe and well-doing of the plants produced by them, it is neceſſary that the action of the fluid which pervades them be duly regulated; for that fluid is operated on in them by the

the ſame cauſes which affect the liquor in a thermometer and barometer, or influence the hygrometer; ſo that whenever its due courſe is obſtructed or weakened, or its quantity too much encreaſed or diminiſhed, or its quality injured in any manner whatever, a diſtemper will enſue. This fluid is ſubject to two laws of motion; the one, ſimply as a fluid, which conſiſts in an inteſtine agitation of its minuteſt particles; and the other, as a fluid whoſe progreſs is through the various ducts of the plant. By the firſt of theſe motions it aſſimilates to itſelf all the homogeneous particles, and expels the heterogeneous; and by the ſecond, it penetrates into the various parts where thoſe functions are to be performed. When both theſe motions proceed naturally, equally, and juſtly, the ſecretions are duly made, and every part of the plant continues ſound and healthy: but when that harmony is interrupted, the fluid degenerates from its natural ſtate, and the ſecretion becomes vitiated and depraved.

"Now, if the ſeveral diſtempers to which plants are ſubject are owing to the various ways in which the regular action of this fluid may be hurt; and no one diſtemper can, in my opinion, happen to corn, which will not fall under one or other of theſe circumſtances, we ought to ſearch after, and endeavour to diſcover them, in order to be thereby enabled to prevent, or to cure them, that mankind may be the leſs expoſed to the injuries reſulting therefrom. But as the knowledge of theſe particular things depends on an adequate conception of thoſe which are univerſal; and as the univerſal cauſes of diſtempers are external or internal, and the diſtempers themſelves ſeem particularly to depend on the conſtitution of the air, or an alteration of food, or on both; ſo when we have diſcovered the genus of the cauſe, it will not be very difficult afterwards to find out the ſpecies, and the efficient cauſe. So many and various have been my reſearches, obſervations, and experiments, and ſuch the lights which they have afforded me, that, if the love of truth did not oblige me to be diffident of myſelf, and if I was not thoroughly perſuaded, with that great philoſopher and mathematician Gallileo, that we cannot in general underſtand how nature acts, becauſe ſhe makes uſe of means frequently beyond the reach of our comprehenſion, I ſhould, perhaps, flatter myſelf with thoughts of having diſcovered the origin of ſome of the diſtempers to which corn is ſubject whilſt in the blade."

He then gives his opinion of mildews, which is, that they come on very early in the morning, and cover the corn almoſt inſtantaneouſly, after a cold night, which has been preceded by a hot day; and that the ſap or moiſture which then iſſues out of the plant, is gradually exhaled, and forms the ruſty powder which characteriſes this diſtemper.

After trying in vain all the boaſted remedies of the ancients (highly commended by ſeveral modern writers) ſuch as burning of ſtraw and weeds in a ſerene night, when not a breath of air is ſtirring, or the wind, if any does blow, comes only from the weſt, ſticking up branches of laurel, &c. ſprinkling the corn with tobacco, and with pepper; and ſtrewing among it, as Dr. Hales adviſes, woollen rags ſteeped in a ſtrong ſolution of ſalt of tartar, or ſea-ſalt, or in good white-wine vinegar, and afterwards well-dried, even from which laſt he cannot ſay that he has found much benefit; the method long ago directed in this caſe by Mr. Worlidge, of making two men go at a proper diſtance from each other in the furrows, holding a cord ſtretched ſtrait between them, and carried ſo as to ſhake off the dew from the tops of the corn, before the heat of the ſun has thickened it, ſucceeded beſt of all; to which he adds as an excellent preſervative, keeping the ground perfectly free from weeds, and ſtirring the earth frequently between the plants. I ought not to omit here Mr. Worlidge's farther obſervation, that "the ſowing of wheat early has been eſteemed, and doubtleſs is, the beſt remedy againſt mildews; for by this means the corn will be well filled in the ear before thoſe dews fall, and the encreaſe will conſequently be the greater. For curioſity ſake, wheat was ſowed in all the months of the year: that ſown in July produced ſuch an increaſe as is almoſt incredible. In France, they generally ſow before Michaelmas.

"Bearded wheat is not ſo ſubject to mildews as the other, its awns keeping the dew from the ear."

MILKNESS, a dairy. *See* DAIRY.

MILLET, the name of a plant which grows naturally in India, from whence it was firſt imported into Europe, is greatly cultivated in Italy, Spain, and the ſouthern parts of France, for the food of men, as well as for that of poultry: and we alſo raiſe it in ſeveral places in England; though we have our annual ſupply of this grain from the Eaſt-Indies, which makes ſome people erroneouſly call it Eaſt-India wheat.

It delights in a light ſandy ſoil, prepared in the ſame manner as for maize; and in ſuch land it branches out into many ſtalks, ſometimes thirty or forty, not unlike reeds either in their ſhape or leaves, of which there is one at each joint. The top of each ſtalk is terminated by a large looſe panicle, which hangs on one ſide, with a chaffy flower, which is ſucceeded by a ſmall round ſeed, about the bigneſs of turnip or cabbage-ſeed, of a yellowiſh white colour in one ſort, and of a dark red, inclining to black, in another. The ſmall millet, and the large, a diſtinction which ſome writers make, are only varieties of the ſame ſort. It is likewiſe ſaid to thrive extremely well in ſtrong land: but will not do in ſtoney ground, or where the bottom is either chalk or clay.

Mr. Miller directs ſowing this grain in the beginning of April, which may be very right in this country, that it may be ripe in Auguſt: but in warmer climates, the general rule is to ſow it either between the middle and the end of May, or at Midſummer. The former is reaped at the end of September, and the latter about the end of October.

The ſeed is ſowed in furrows, very thin, and covered with the plough or rake. The largeſt ſort ſhould be ſowed thinneſt, becauſe it branches moſt. When the plants are about a month old, the ground ſhould be ſtirred round them with a hand-hoe, as well to lay freſh earth to their roots, for they require a great deal of nouriſhment, as to clear them from weeds, of which they will afterwards prevent any great increaſe, by over-topping them. At the ſame time, the millet ſhould be thinned wherever it grows too cloſe, ſo as to leave, in general, about ſix inches between each plant. The huſbandman has nothing more to do to this grain till harveſt, excepting that, when it begins to ripen, he muſt take great care to protect it from birds, which would otherwiſe ſoon devour it. If preſerved from them, the returns are very great; for it is not eaſily hurt by drought or rain, nor is it ſubject to blight. Frequent ſhowers of rain are of great ſervice to it whilſt growing.

When the millet is ripe, its panicles are cut off near

the uppermoſt joint of the ſtalk, with a knife, and put into baſkets or ſacks, in which they are carried home. They are then laid up in heaps, covered over with cloths, and after remaining in that ſituation five or ſix days, are ſpread upon the barn floor, threſhed out with a flail, and cleanſed, like other grain. Great care muſt be taken to dry it well in the ſun, before it is laid up in the granary: for it would ſoon ſpoil if the leaſt moiſture were left in it; this being of all grains the moſt difficult to keep, unleſs it be thoroughly dry: and, on the other hand, none keeps longer or better, after it has been well dried. It is not liable to the weevil: and tho' it ſhould be turned from time to time in the granary, yet if that happens now and then to be neglected, it ſtill keeps perfectly well.

It has been a conſtant obſervation, that the late ſown millet, I mean ſo late as Midſummer, had always had the greateſt number of abortive grains; that its panicles are ſmaller than thoſe of the ſame grain ſowed earlier; and that the crop was leſs plentiful.

The ſmall white millet, which is by far the moſt delicate, and of which excellent puddings, &c. are made, is the ſort chiefly cultivated in this country. The red, which is much larger and coarſer, is not uſed here, except, perhaps, for pigeons, poultry, and ſwine, for which laſt it ſhould be ground to meal: but the peaſants about Bourdeaux, where a great deal of it is raiſed in the poor light lands near that city, make of it a reddiſh, heavy, ill-taſted bread, difficult to digeſt. The culture of this ſort, which is Mr. Miller's *ſorgum*, is, in all reſpects, the ſame as that of the white; excepting that, as it grows much larger, the plants require more room.

Millet, either green, or after its grain is threſhed out, is very good fodder for cattle, for which uſe it may be ſowed thicker than for a crop of grain. Its many roots, large ſize, and quick growth, are ſaid to render it a great impoveriſher of the earth; for which reaſon ſome people pull up the roots, and plough the ground immediately, as ſoon as the crop is reaped: but others, more judicious, plough in the ſtubble and roots, which rot, and greatly enrich the ſoil: and indeed all other ſucculent plants, inſtead of being ſuch robbers as is commonly ſuppoſed, return to the earth, by the inſpiration of their leaves and perſpiration of their roots, even while they grow, perhaps as much as they borrow from it: for how ſhould it be poſſible for them to pierce into the very drieſt and hardeſt ground, as we frequently ſee they do, unleſs they perſpire moiſture through their roots? As this plant requires a great deal of nouriſhment, it would probably thrive beſt in the horſe-hoeing huſbandry.

The following account of the culture and amazing produce of the African millet, was ſent by the ingenious Mr. Burton, to the editors of the Muſeum Ruſticum.

"I cannot help mentioning to you, for the ſake of your practical readers, the African millet, *ſorghum*, *milium nigrum*, the culture of which is ſtrongly recommended by M. Tſchiffeli, who has written a paper on the ſubject, publiſhed in the Tranſactions of the Berne Society. There is ſomething ſo very extraordinary in this paper, that I am ſure you will think a ſhort abſtract of it worthy to be inſerted in your work.

"Monſ. Tſchiffeli obſerves, that this millet is a plant which merits the huſbandman's utmoſt attention, and that for the following reaſons: 1. It thrives in all ſorts of ſoils. 2. It neither requires much dung, nor a great deal of tillage. 3. It is not ſubject to the depredations of birds, which are very fond of panic and common millet. 4. It yields very large returns. 5. Laſtly, it does not exhauſt the land in proportion to the largeneſs of the crops.

"He farther ſays, that the ſeed of this ſort of millet comes originally from Africa, where it ſupplies the inhabitants with food; but that they are miſtaken who thence conclude it will thrive only in hot countries: for providence has endowed it with ſuch excellent qualities, that it may, with ſucceſs, be cultivated in countries much colder than Switzerland.

The firſt ſeed of it M. Tſchiffeli received was from Mr. Engel, magiſtrate of Eſchalens, who procured it from Pomerania, it being ſent to him by the celebrated doctor Schreber, in the ſpring of the year 1760. M. Tſchiffeli had from him about a ſpoonful.

"In the month of May of the ſame year, he ſowed it on a gravelly ſoil, hard and ſtony, very much expoſed to the north wind, and which the year before had borne ſome very indifferent bere. In the month of February preceding, ſome human ordure had been laid on this land; and in May the clods were all broken before the ſeed was ſpread: having ſo ſmall a quantity of ſeed, he took care to ſpread it very thin; and to this does he aſcribe the ſtalks running to the height of eight feet or more. The ears were above ten inches long; and if a ſhower of hail had not fallen on it, the ſpoonful probably would have produced him at leaſt a peck. This accident occaſioned the loſs of half his ſeed: he had, however, enough left to divide with his friends in Switzerland, as well as elſewhere.

"In the month of May, 1761, he ſowed about a quart of ſeed, or near a pound, on ſome land, from which he had firſt pared off the turf, and afterwards burnt it. The ſpace on which the ſeed was ſown might be about twenty paces long, and ten broad.

"Some time before harveſt, M. Tſchiffeli perceived he ſhould have allotted three times as much ground for that quantity of ſeed. The ſtalks, which were very cloſe, were interwoven one with the other, like the hairs of a bruſh. They were ſcarcely five feet in height, and the ears alſo were much ſhorter than the preceding year: this, however, did not prevent his reaping about ſeven pecks, or above fifty for one. In the year 1762, he ſowed about four pounds of ſeed, or about half a peck, on ſome pretty good land, being in quantity about thirty ſquare rods or perches. The year before, the ſame land bore potatoes; and as he had laid on no freſh manure for the millet, and had neglected to plough it before the winter (for it was only turned over with a ſpade before ſowing) he imagined he had not ſown the ſeed too thick: but in this he was greatly miſtaken; the millet came up almoſt as thick as the year before, and as he had not the courage to thin it, which would have been right, the ſtalks and ears were ſhorter than the firſt year.

"Notwithſtanding this, he was enabled to reap twenty buſhels, being ſix hundred and forty pounds; of courſe, a return of a hundred and ſixty for one.

"There can then be no reaſon to doubt, but that land of a moderate quality, ſown thin, and properly prepared, will produce, one year with another, one hundred buſhels of millet per acre; for our huſbandman got as much in proportion, though his land was but ſlightly tilled, and he manifeſtly ſowed his ſeed too thick. This is certainly a moſt wonderful increaſe, in what light ſoever we behold it.

"What

"What grain is there which in the open field will yield a return of one hundred and fifty for one, and which, at the ſame time, will ſell ſo well, for in price it is on a footing with wheat? It is true, it yields a heavy, crumbly, and indifferent bread; but if it is made into pottage, it is excellent, very nouriſhing, and of exquiſite flavour. Not only M. Tſchiffeli's ſervants and workmen were very fond of millet thus prepared; but he himſelf prefers it to the beſt rice, which will not grow in Switzerland, and comes at a much higher price.

"The millers in Switzerland, whoſe reputation is not of the beſt, return a good third of a buſhel of millet-meal for every buſhel ſent to them, after deducting toll, bran, waſte, &c. Now this ingenious writer knows by experience, that ſuch a quantity, when made into pottage with milk, will ſerve at leaſt fifty men for a meal. Surely they cannot be fed at a cheaper rate. In times of ſcarcity millet muſt be of great uſe, as with potatoes the poor might live comfortably.

"An acre of land requires, at moſt, but ten pounds of ſeed; and M. Tſchiffeli ſays he can, from his own experience, venture to aſſert, that millet does not impoveriſh land in proportion to its produce. The land he ſowed in 1760 and 1761, yielded, the following year, fine plants of Dutch clover, and rye-graſs in as great plenty, with reſpect to the crops, as the neighbouring land."

MILL-HOLMS, watery places about mill-dams.

MISLEN, the ſame with maſlin, or maſlin-corn. *See* MASLIN-CORN.

MIST, a meteor conſiſting of groſs vapours floating near the ſurface of the earth.

The bluiſh miſt, which we ſometimes ſee on our fields and paſtures in a morning, though often innocent, yet has been in ſome places found to be the actual cauſe of murrain, and other fatal diſeaſes among the horned cattle.

Dr. Winklar gives, in the Philoſophical Tranſactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently ſeen to ſpread itſelf over the countries in the form of a blue miſt. Wherever this was perceived, the cattle were ſure to come home ſick; they appeared dull and heavy, and refuſed their food; and many of them would die in four and twenty hours. Upon diſſection there were found large and corrupted ſpleens, ſphaceous and corroded tongues; and in ſome places thoſe people who were not careful of themſelves, in their management of the cattle, were infected and died as faſt as themſelves. The principal cauſe of this diſeaſe ſeemed to be the exhalation of ſome unwholeſome ſteams from the earth; and it was obſervable that there had been three earthquakes in Italy the year before it happened. The method of cure which ſucceeded beſt, was this: as ſoon as any beaſt appeared to be ſick, they examined the tongue, and, if apthæ, or little bliſters, were found on it, they ſcraped it with a ſilver inſtrument made with ſharp teeth at the ſides, till it bled in all thoſe parts where the apthæ were; the blood was then wiped away with a cloth, and the whole tongue waſhed ſeveral times with vinegar and ſalt. After this, the following medicine was given internally: take of ſoot, brimſtone, gun-powder, and ſalt, of each equal parts; mix theſe in as much water as will make them thin enough to be ſwallowed, and let a ſpoonful be given for a doſe three or four times a day. The cattle which were in health had this medicine given them, as well as the ſick; and the conſequence was, that very few died in Switzerland, while almoſt all died in other places.

It was very remarkable that the contagion, on this occaſion, ſeemed to travel ſlowly and regularly on; it came at the rate of about two German miles in twenty-four hours: this it kept regularly to, during the whole time of its raging, and never appeared in very diſtant places at the ſame time.

The whole ſurface of the earth emitting theſe effluvia, no cattle eſcaped them in the courſe of their way; but thoſe which were kept within doors at rack and manger, fell ill at the ſame time, and in the ſame manner with thoſe in open fields. Dr. Slare was of opinion, that it was owing to certain inſects which could not fly faſter than at the rate of two German miles a day; and that they travelled regularly, and ſpread the miſchief where they paſſed; but there wanted ſome judicious perſons, verſed in theſe obſervations, to have examined both the ſtate of the air, and the beaſts, on this occaſion. *Philoſ. Tranſactions*, Numb. 145.

MIXEN, a dung-hill.

MIZZY, a bog, a quagmire.

MOAR-LOVRE, a term uſed to expreſs a peculiar diſtemperature of corn, generally comprehended under the common term of a blight. In this caſe the earth ſinks away from the roots of the corn, and leaves the plant ſtanding in great part above ground with naked roots; theſe being too weak to ſupport the ſtalks, the plants fall, and the ears become light. This is a diſtemperature peculiar to corn growing on light and looſe lands. *Tull's Horſe-hoeing Huſbandry.*

The remedy is this: turn a ſhallow furrow againſt the rows, when they are ſtrong enough to bear it, and the mould is fine and dry; the motion of the ſtalks with the wind will draw in this looſe powder, and it will ſpread itſelf equally among all the rows, ſettle about the roots, and cover them.

MOLE, a ſmall animal too well known to the huſbandman, from the miſchief it does in the fields, by looſening of the earth, and deſtroying the roots of corn, graſs, and other vegetables.

The common method of deſtroying them is by traps, made in the following manner:

Take a ſmall board, about three inches and a half broad, and five inches long: on one ſide thereof raiſe two ſmall round hoops or arches, one at each end, like the two hoops or bails of a carrier's waggon, capacious enough for a mole to creep through eaſily: in the middle of the board make a hole about the bigneſs of a gooſe-quill, and have in readineſs to put into it a ſtick about two inches and a half long, fitted at one end to the hole, and a little forked at the other. Cut alſo a hazel or other ſtick, about a yard, or a yard and a half long, which will riſe with pretty ſtrong elaſticity, when it is ſtuck into the ground; and to the end of this ſtick faſten a very ſtrong nooſe of horſe-hair, made ſo as to ſlip eaſily. Have likewiſe in readineſs four ſmall hooked ſticks: then go to the furrow or paſſage of the mole, and after you have opened it, fit in the little board with the bended hoops downward, ſo that when the mole paſſes that way, it may go directly through the two ſemi-circular hoops. But before you fix the board in this manner, put the hair ſtring through the hole in the middle of it; place the nooſe in a circular form, ſo as to make it anſwer to the two hoops; put the ſmall ſtick before-mentioned gently into the hole in the middle of the board, ſo as juſt to ſtop the knot of the hair ſpring, without entering ſo far as abſolutely to tighten it. Then faſten

the

the board down with four hooked ſticks, and cover it with earth. When the mole, paſſing in its furrow, comes into this trap, it will diſplace the ſmall ſtick that hangs perpendicularly downward, the knot will then be drawn through the hole, and the nooſe inſtantly ſtreightened by the riſing of the end of the hazel ſtick to which it is faſtened, which will catch the mole round the neck.

Others, watching their motions in the morning and evening, which are their uſual times of ſtirring, dig them out in a moment with a ſpaddle: and about March which is their time of breeding, numbers of their young ones may be deſtroyed by turning up their neſts, which are generally in the greateſt hills; and the old ones who come to ſeek their young will preſently be taken.

Some commend the pot-trap, which is a deep earthen veſſel ſet in the ground with the brim even with the bottom of the mole tracks. The ſeaſon for uſing this is when the moles couple, which is about the beginning of March, or perhaps ſomewhat earlier.

Mr. Worlidge ſays, they may be driven from the gardens, meadows, and other places where one would not chooſe to dig, by fuming their holes with brimſtone, garlick, or other unſavoury things: and that the putting a dead mole into a common haunt, will make them abſolutely forſake it: to which Mr. Mortimer adds, but only upon report, that white hellebore and the roots of palma-chriſti, dried, powdered, and ſifted through a fine ſieve, then mixed with barley-meal and eggs, and worked into a paſte with wine and milk, will kill them, if laid in little pellets under their hills.

The writers of the Memoirs of the Society of Agriculture at Angers, recommend hazel-nuts boiled in an infuſion of hellebore, as a ſure method of deſtroying moles. Two or three of theſe nuts are to be laid under each mole hill, and the creatures, by being fond of that fruit, will be poiſoned by eating them.

The way to remove mole-hills and ant-hills, which are not only diſagreeable to the ſight, but detrimental to the paſture, and a great hindrance to the mowing of the graſs, eſpecially where they are numerous, is particularly in regard to the latter, either to divide the turf which grows over them, into three parts, with a ſpade, or other inſtrument, then to pare it off each way, to dig out the middle or core of the hills, to ſpread this mould over the other ground, to leave the holes open all the winter, that the ants may be killed, or lay the turf down again in the ſpring, and to roll thoſe ſpots after the re-inſtated turfs are ſettled, and their graſs has taken freſh roots; or, which is a more expeditious method, to ſcoop them out at once, with what Mr. Bradley calls a ſcolloped mole-hill plough, made in the following manner.

From *a* to *a* (Fig. 1. Plate XX.) is an iron plate, about five inches over, and above an inch thick at the back, *b b* is the ſcolloped ſpade, or tongue, of the plough, and about a foot over at the wideſt part. This, from the ſharp point, grows thicker by degrees, till it comes to the back, which ſhould be a full inch thick. The iron muſt be well hardened, and very ſharp at the edges. *c c* is the paring plate, which ſhould be very ſharp on the fore edge, and, with the ſcolloped ſpade, ſhould be four feet long from *a* to *a*. *d d* are iron ſockets, in which are fixed the plough handles, or ſtilts, *e e*. At *a a* are foot-links to ſet the harneſs on, for one horſe, or two horſes lengthwiſe, to draw by.

When this plough is uſed, the point of the ſcolloped ſpade muſt be ſet to the bottom of the hill, by raiſing the plough ſtilts, ſo that it may go into the ground; and when the hill is near cut through, the point ſhould be raiſed up again, by weighing a little on the ſtilts.

The hollow left by this plough will receive the rain as it falls, and this will drown the remaining ants.

After the mole and ant-hills, and other inequalities have been thus taken off, the beſt way is to carry them to a corner of the field, there to break them well to pieces, and mix them with a conſiderable portion of lime, or other manure ſuited to the ſoil, which will effectually deſtroy every remains of the ants, and convert the whole to good manure, which may then be profitably ſpread all over the ſurface of the ground. The ſpots on which the mole, or ant hills ſtood, ſhould be looſened with a ſpade, then mixed with lime or other manure, and afterwards be laid down with clean graſs ſeeds.

This method is the moſt adviſable of any, becauſe a fine graſs will be raiſed in thoſe places, inſtead of the coarſe benty growth which occupied them before.

MOLTEN-GREASE, a fat or oily diſcharge with the dung, and ariſes from a colliquation, or melting down of the fat of the horſe's body, by violent exerciſe in very hot weather.

It is always attended with a fever, heat, reſtleſſneſs, ſtarting and tremblings, great inward ſickneſs, ſhortneſs of breath, and ſometimes with the ſymptoms of a pleuriſy. His dung will be extremely greaſy, and he will fall into a ſcouring; his blood will have a thick ſkin of fat over it when cold, of a white or yellow hue, but chiefly the latter; the congealed part, or ſediment, is commonly a mixture of ſize and greaſe, which makes it ſo extremely ſlippery, that it will not adhere to the fingers, and the ſmall portion of ſerum feels alſo ſlippery and clammy. The horſe ſoon loſes his fleſh and fat, which probably is diſſolved and abſorbed into the blood; and thoſe that ſurvive this ſhock commonly grow hide-bound for a time, their legs ſwelling both before and behind, and continue in this ſtate till the blood and juices are rectified; and if this is not done effectually, the farcy, or ſome obſtinate ſurfeit, generally follows, very difficult to remove.

In the firſt place bleed plentifully, and repeat it two or three days ſucceſſively in ſmaller quantities; two or three rowels ſhould alſo be immediately put in, and cooling emollient glyſters, daily thrown up to abate the fever, and drain off the greaſy matter from the inteſtines. By the mouth give plenty of warm water, or gruel, with cream of tartar, or nitre, to dilute and attenuate the blood; which in this caſe is greatly diſpoſed to run into grumes, and endanger a total ſtagnation.

When the fever is quite gone off, and the horſe has recovered his appetite, gentle aloetic purges ſhould be given once a week, for a month or ſix weeks, in order to bring down the ſwelled legs; but if the purgative ingredient does not exceed half an ounce, or ſix drams of fine aloes, it only opens the belly gently; and, with the other medicines joined with it, paſſes into the blood, acts as an alterative, and operates both by urine and perſpiration; as will appear by the horſe's ſtaling plentifully; and the kindly feel of his ſkin. To this end give the following, which, repeated for ſome time, will intirely remove this diſorder.

Take

Take of ſuccotrine aloes ſix drams, of gum-guaiacum powdered half an ounce, of diaphoretic antimony, and powder of myrrh, of each two drams: make into a ball with ſyrup of buckthorn.

Or it may be prepared with an ounce of aloes, ſix drams of diapente, and a ſpoonful of oil of amber.

Theſe will ſeldom take a horſe from his buſineſs above two or three days in a week; neither will he loſe his fleſh or appetite with them, which cannot be obtained by any other method of purging, and gives this greatly the preference in many caſes.

Two ounces of nitre mixed up into a ball with honey, and a dram of camphire, will alſo be found an excellent medicine for this purpoſe, as it will powerfully attenuate the blood, and promote the due ſecretions; to which end it ſhould be given every day for a fortnight, or three weeks. *Bartlet's Farriery, page* 168.

MOLTER, the toll of a mill.

MOOR, a very fine black mould, ſometimes found under a pretty thick ſward of graſs, but more frequently under moſs, or ſtraggling plants of heath.

It differs from peat, in that it does not ſtick together, nor has the fibrous roots, or bituminous viſcous quality of this laſt. Peat, when dry, becomes hard and firm: this falls into powder. It cannot be better deſcribed, than by comparing it to that ſubſtance which is found in hollow rotten willows, and other trees of that kind; which gives room to think that it ariſes from rotten plants. It is of a ſpungy nature, and ready to imbibe moiſture, which adds conſiderably to its weight. There is generally underneath it, as under moſt earths of this kind, a bed of clay, or ſome ſubſtance impervious to water: ſo that the particles of bodies decayed on their ſurface, not being admitted into the ſoil, remain upon that ſurface, dry there, and increaſe its thickneſs, according to the continuance of the cauſe.

If this kind of ſoil is collected in a place where running water, in rainy ſeaſons, brings with it clay, or other fat ſoils, from the neighbouring grounds, it then acquires a greater degree of coheſion, hardens when dry, and reſembles the cleanſing of ponds, more than the former.

The moſt conſiderable ſoil of this kind is the ſort called peat. This is uſually full of roots of weeds, and even of trunks and branches of trees and other plants. It always contains a bituminous oil, which renders it very inflammable when dry; at which time it alſo becomes very hard, though it is quite ſoft when in the mine, if we may be allowed to give that name to the bed in which it lies; for there it is eaſily cut in the form of bricks, as we ſee it when uſed for fuel.

"The whole maſs and body of this ſoil, ſays Mr. Maxwel, is a dung-hill, made up of rotten timber, graſs, weeds, and often mud waſhed from the higher grounds about it, by the land-floods; than which there are few richer compoſts: only by age, and its cold ſituation in water, pent in about it by the neighbouring riſing grounds, its ſalts are weakened, and its ſpirits become languid. The ſame will happen to the richeſt dunghill that can be made of any compoſition whatever, if too long kept. It will even become ſuch as not to be diſtinguiſhed, by the eye, from ordinary moſs; nor will it be more uſeful, as dung, except either in proportion to the ſhorter time it has been kept, or the better ſituation of the place where it has ſtood. I believe the qualities of moſſy grounds differ very little from one another in any other reſpect, than with regard to the better or worſe quality of the mud which makes a part of their compoſition. They are more or leſs ſpungy, in proportion as this rich mud fills up the cavities of the component vegetables, which are preſerved from putrefaction by the acid in the water. The leſs ſpungy, and the more rotten the moſs is, the fitter it is for the vegetation of any thing planted in, or ſown on it."

The firſt thing to be done, in order to the improvement of moors, is to divide them into proper incloſures; not only to ſecure their future produce, but alſo to be a means of procuring rich earth to cover the otherwiſe inſipid uſeleſs mould on the ſurface, and give root to the plants which may afterwards be cultivated in them. Then, as the natural produce of this earth is of no value, its ſurface ſhould be pared off, in order to be burnt. But as this ſubject, of burning earth, has been before fully treated of, we ſhall only obſerve here, that the huſbandman ſhould be very careful not to make the clods too dry, or light his fires in too dry a ſeaſon, leſt they ſhould extend farther and deeper than was intended.

If the depth of the mooriſh earth be not very conſiderable, the ſurrounding ditches, which make the incloſure, will afford a rich ſtrong ſoil, which ſhould be ſpread about three or four inches thick all over the ſurface. When the clods are burnt, their aſhes ſhould be mixed with this new ſoil. If no proper earth can be got from the ditches, ſand or gravel may be uſed with ſucceſs, as was practiſed by the ancients. Gravel is ſingularly beneficial to ſuch lands, as has been ſhewn under the article Bog.

The Berne Society, who recommend this method of improvement as founded on repeated experience, very properly obſerve, that the good effects of the ſand and gravel will be conſiderably increaſed by a moderate mixture of dung, and that, eſpecially if the ground be intended for plowing, this covering ſhould be at leaſt a hand's breadth in thickneſs. Dung alone would undoubtedly be extremely efficacious on all ſuch ſoils, in which it is remarked to be of longer ſervice than in any other; but the farmer can ſeldom ſpare a ſufficient quantity of it to go far enough unmixed, nor indeed for mixing. In this caſe, other ingredients muſt be recurred to; though the ſand, or gravel, will generally do great things without any mixture. Well preſerved aſhes will be of excellent ſervice, and ſo will the rubbiſh of old building, or any other ſimilar ſubſtance, when mixed with the ſand or gravel, even of the coarſer kind, and incorporated with this naturally rich earth, which, were its real value known, and the proper method of treating it rightly underſtood, might claim a preference before any other ſoil. Loam is ſtill better than either ſand or gravel. This ſhould be brought on before the fires are lighted to burn the ſurface of the moſs, and ſhould remain in heaps till it can be equally mixed with the aſhes. Lime, where it can be had, will alſo contribute to the meliorating of moſſy grounds. The mooriſh earth, thus covered, is fitted for various kinds of crops.

Mr. King, who obſerved that the places in bogs in Ireland, where a little earth had chanced to fall as the peaſants were carrying it to mend the ways acroſs them, became a green ſod, covered with a fine ſcutch graſs, does not doubt but that the ſame expence as ſands or gravels land, would bring a dried bog even to be arable; and as to the common opinion that gravelling is bad for graſs, the contrary,

contrary, he ſays, is apparent; eſpecially in bogs. Another method of reducing barren boggy land, in Ireland, is by laying upon it a little dung or ſtraw, and covering this with ſhells.

A ſtrong proof of the propriety of covering moſs with earth, reſults from a fact which happened to Mr. Græme, near Stirling. Two years after this gentleman had earthed his moſs, which he had not yet ſowed, it was as full of natural white clover, and other graſs, as any field generally is in twice that time.

In the province of Groninguen, they pare off the upper ſurface of the ſoil, which is a light looſe earth, and lay it by till they have dug out the peat underneath, when they mix it with the ſand which lies under the peat, and ſow it with rye and hay-ſeed the firſt year; after which they let it run to graſs, and have amazingly fine crops. In Sweden, a drained bog was remarkably improved by a peaſant who burnt upon it a parcel of uſeleſs wood and lime-ſtones; and another converted his drained bog into a fine meadow, by covering it with lime and tanner's bark.

Mr. Elliot, after draining a very remarkable ſwamp, ſowed it with graſs-ſeed, ſuch as red clover, ſpear-graſs, fowl-meadow graſs, and herd-graſs; none of which came up ſo well as the red clover, which he found to be the boldeſt and moſt hardy. Though this came up well, yet, where the ſward was ſtrong, what with the toughneſs of the ground and the over-topping growth of the wild natural graſs, it made but ſlow progreſs till the fall of the year, and then it mended conſiderably. The other ſorts of graſs came up but poorly, the land being, as Mr. Elliot judges, too new and tough for them. In September, he ploughed up a piece of this ground, where he had not ſowed any graſs. It ploughed very tough, and the cattle mired in ſome places; but he kept them as much as poſſible upon the graſs; notwithſtanding which there was a neceſſity of leaving many baulks. About a month after, he ordered theſe baulks, to be hoed up, and was agreeably ſurpriſed to find how eaſily this was done. He found the meadow rotted and mellowed more in one month in the fall, than it had been in the whole ſummer; but thinks the ploughing would have been performed with much greater eaſe, if it had been deferred till a month later. In July, he ſowed a little piece with turnips, which came up, but did not grow well till the ground began to rot in the fall of the year, when they throve perfectly, and were good and ſweet, inſtead of being rank, as he expected.

This gentleman found by experience, that ſuch drained land muſt have one ſummer to ferment and rot, ſo as to become proper ſoil, before it will be fit for grain or every ſort of graſs. "If, ſays he, I had ſowed red clover inſtead of the other ſorts of graſs, I had ſaved five pounds in ſeed. Clover out-did my expectation, and the other ſorts fell ſhort of it. If others ſave where I loſt, and mend wherein I was miſtaken, it anſwers my deſign in writing.

"By a little experience which we have had of theſe drained lands, we find they will produce Indian corn, ſixty or ſeventy buſhels to an acre, and flax. If life and health be continued, I deſign to try liquorice-roots, barley, Cape-Breton wheat, cotton, indigo-ſeed, wood for dying, and the water melon. But what I have principally in view is hemp. New-England doth not, I ſuppoſe, expend leſs than ſeveral hundred thouſand pounds worth of foreign hemp yearly. If we can raiſe more than to ſupply our own occaſions we may ſend it home. It is not a mere conjecture, that the drained lands will produced hemp. I am informed by my worthy friend Benjamin Franklin, Eſq; of Philadelphia, that they raiſe hemp there upon their drained lands.

"Hemp requires ſuch very ſtrong land to produce it, that it would conſume all our dung to raiſe it in any great quantities; ſo that we ſhould not be able to raiſe bread-corn: therefore, how inviting ſoever the trade is, and how great ſoever the encouragements have been, both from home and by our own government, we have not as yet engaged in that affair. We have now a promiſing proſpect of ſucceſs in theſe drained lands: what may be the iſſue, time and experience muſt determine. A meadow of drained land, which could be laid under water, and this drawn off at pleaſure, would probably be of great value. I have heard that a man in the Jerſies hath ſuch a meadow, which though only half an acre in extent, yields him as much hemp yearly, as ſells for fifty pounds, York money: but this ſeems incredible."

Whatever advantages are reaped from hemp, may alſo be received from flax, if rightly managed, upon moſſy grounds. Some improvers in Scotland have already tried it with ſucceſs, and though, a new attempt, doubt not its anſwering well in that kind of ſoil. The moſt approved method of cultivating and dreſſing each of theſe ſingularly beneficial plants, are given under the articles HEMP and FLAX.

"It is common in ſwamps, continues Mr. Elliot, to find the moſs two or three feet deep. At firſt, I was perplexed how to get rid of it, and ſomewhat doubtful whether the land would be worth any thing, if this ſurface was removed. When the water was drawn off by ditches, the moſs grew ſo dry, that in a hot ſummer ſeaſon, it would burn quite down to the ground. To burn this, or any other traſh you would conſume upon land, ſet fire to it when the weather is clear, the ſun hot, and a ſtrong ſoutherly wind blows, which makes fire rage more fiercely and do much more execution, than a northerly or weſterly wind. In a northerly wind the air is thin and light, ſo that the fire is not ſtrongly compreſſed: the moiſt heavy ſouth wind prevents the diſſipation of the fire, and renders it more compact. Thus we ſee a ſmith ſwab and wet his coals, by which means the heat is greatly increaſed. Whether this reaſoning be juſt or not, the fact is certain, and that is the chief concern of the farmer.

"Deep ſwamps are preferable to thoſe which are ſhallow: for experience ſhews, that a deep ſoil bears extreme drought better than any other land, in the hot ſeaſon. The cold drought in the ſpring will hurt ſuch land, ſo that the firſt crop of graſs will be very great; but the ſecond crop will be extraordinary good.

"The red clover in my drained land above-mentioned, looked in the cold drought at the latter end of the ſpring, as if it would not come to any thing: but it recovered a good colour, and grew up well, when hot weather came on, though the drought continued. This is ſuch an advantage as will always recommend a ſoil eight or ten feet deep.

"Our ditching and draining dry only the top of the ground, not more than three feet deep in the hot and dry ſeaſon; I ſuppoſe that the moiſture from the mud and water underneath is drawn by the force of the ſun, ſo that the roots of the graſs are furniſhed with ſufficient moiſture

moiſture to bring forward the vaſt burden they frequently bear. But this is not to be expected till the land be concocted, changed, and altered by the ſun and air: for at firſt, ſoon after it is drained, it is pinched with the drought more than any other land.

"Thoſe ſwamps which are thick overgrown with moſs, prove as good as any other drained land, when they are ſo far dried by draining, that the moſs will rot, or burn off. I mention this, becauſe it is beſt that the farmer work as free from diſcouragement as poſſible.

"Our drained land, though in all other reſpects well adapted for producing Indian corn, is of ſo looſe a texture, that the plants become an eaſy prey to crows and other birds, which, if not prevented, will pull up a great part of them, and deſtroy the crop. To guard againſt this great diſcouragement in all ſuch land,

"Take the roots of ſwamp hellebore (known in different places by the ſeveral names of ſkunk-cabbage, tickle-weed, bear-root) and boil them in ſo much water as to keep them covered an inch deep: by two hours boiling, the liquor will be of ſufficient ſtrength: ſtrain it off; put your corn into it while the liquor is warm, and let it ſteep twenty hours. It will then be fit for planting.

"This is found to be an effectual ſecurity. The Rev. Mr. Todd obſerves, that after meeting with much trouble and loſs, by having his corn repeatedly pulled up, he planted his ground with corn ſteeped in this liquor; but not having enough of that, he ordered the planting to be finiſhed with unſteeped corn. The event was, that the birds pulled up but two or three hills of the ſoaked corn, but left not one in ten of thoſe which were planted with unſoaked corn. He planted anew, with ſteeped corn, the hills where the plants had been thus pulled up, except a few of them in the middle of the field, which were planted a ſecond time with unſteeped corn, upon a ſuppoſition that the birds would not find them out: but the reſult was as before: all the unſoaked was pulled up, and the hills planted with the ſteeped corn were ſpared.

"Upon the whole," ſays Mr. Todd, "I think this experiment a full proof that corn ſo prepared when planted, is ſecured from the birds; the knowledge of which may be of great ſervice to huſbandmen, as the preparation is cheap and eaſy, and our ſwamps ſeem to be the beſt land we have for Indian corn. My little ſwamp this year yielded after the rate of above ninety buſhels to the acre, and was eaſier and cheaper tilled than the ſame quantity of upland." *See the article* BOG.

MORES, or *Mours*, hills.

MORGAN, the ſame with May-weed. *See the article* MAY-WEED.

MOSS, a name given to moory or boggy grounds, in many parts of England. Theſe ſorts of land conſiſt of a turfy ſurface, below which is a black, moiſt, ſpongy earth, which being dug up with ſpades, almoſt in the form of bricks, and dried, is what they call peat, and uſed as fuel in ſeveral parts.

The ſhorteſt method of all for the improvement of moſs, if the ground be deſigned only for graſs, and its ſituation be ſuch as admits of it, is this: firſt drain the moſs, and if there be heath upon it, burn that off, and make the ſurface even. Then make a dam at the loweſt part, and a ſluice, and work the water upon it through the winter. The mud which comes with the land flood will bring a fine ſward upon it in two or three years, and be afterwards a yearly manure; ſo that it will bear annual cutting, and, beſides, be good paſture for cattle, after the ſward is become ſtrong enough to bear them.

Mr. Græme found that the improvement of moſs may be endangered by draining it too much; for his crops were beſt where the ſurface of the water in the ſurrounding ditches was not above three feet lower than the level of the moſs. It will, undoubtedly, be a vaſt advantage to an improved moſs, if the farmer is able to flood it at proper times, by means of a ſluice in the loweſt part of the ſurrounding ditch, as mentioned before. This will greatly promote the growth of plants; but ſhould be uſed with the caution of not letting the water remain too long at a time upon the ground, becauſe, though there will be no danger of its re-converting the ſoil into a bog ſo long as there are channels to carry it off, it will be apt to chill, and thereby hurt the plants. *See the article* BOG, *and* MOOR.

MOSS *on Trees*, is a diſtemper of very bad conſequence to their increaſe, and much damages the fruit of the trees of our orchards.

The preſent remedy is the ſcraping it off from the body and large branches, by means of a kind of wooden knife, that will not hurt the bark; or with a piece of rough hair-cloth, which does very well after a ſoaking rain. But the moſt effectual cure is, the taking away the cauſe. This is to be done by draining off all the ſuperfluous moiſture from about the roots of the trees, and may be greatly guarded againſt in the firſt planting of the trees, by not ſetting them too deep.

If trees ſtand too thick in a cold ground, they will always be covered with moſs; and the beſt way to remedy the fault, is to thin them. When the young branches of trees are covered with a long and ſhaggy moſs, it will utterly ruin them; and there is no way to prevent it, but to cut off the branches near the trunk, and even to take off the head of the tree, if neceſſary, for it will ſprout again; and if the cauſe be in the mean time removed by thinning the plantation, or draining the land, the young ſhoots will continue clear after this.

If the trees are covered with moſs, in conſequence of the ground's being too dry, as this will happen from either extreme in the ſoil, then the proper remedy is, the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to ſome diſtance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of moſs, but it will alſo prevent the other great miſchief which fruit-trees are liable to in dry grounds, which is, the falling off of the fruit too early. *Mortimer's Huſbandry.*

Falſe MOTH, an inſect which proceeds from a ſmall caterpillar, the body of which is ſmooth and whitiſh. It has ſixteen legs, does not lodge in the grains of corn, but contrives to faſten ſeveral of them together with a web which it ſpins, and with which it makes itſelf a dwelling place like that of common caterpillars. This dwelling place, or ſheath, in which the caterpillar of the falſe moth uſually abides, is generally in the middle of the little heap of grains which it has collected for its food: but, which diſtinguiſhes it from the caterpillar of the true moth, it can quit this ſheath at any time, to eat the grains around it, one after another. It generally attacks ſeveral grains

at once, and always without order, eating ſometimes of one, and ſometimes of another; ſo that ſeveral are gnawn, when not one is wholly conſumed. When theſe inſects are very numerous in a granary, all the grains upon the ſurface of the corn are linked together by a web, ſo as to form a cruſt, which is ſometimes three inches thick. This caterpillar turns into a chryſalis, or aurelia, in a grain which it has hollowed, or in the ſheath of its web, and iſſues from thence, in the month of June, in the form of a butterfly. When a heap of corn is ſtirred in which there are many caterpillars of the ſpecies of this falſe moth, thoſe inſects crawl up the walls; but they ſoon return to the heap, and, by the very next day, cover it all over with a new web.

In its ſtate of moth, it is grey, has ſix legs, and is frequently ſeen in vaſt numbers fluttering about the eaves of the windows of granaries, in the ſpring and ſummer, when the weather is very hot. The females lay their eggs upon the heaps of wheat, and theſe eggs produce the caterpillars, or corn worms, as ſome call them, which feed on the grain, and envelop it with their ſilky web, ſo as to form over the whole ſurface a cruſt that is ſometimes three or four inches thick. This entirely ſpoils the corn within that depth, beſides communicating a bad ſmell to all the reſt. Theſe worms, or rather caterpillars, for they have ſixteen legs, are ſmooth, whitiſh, and ſeldom exceed a quarter or at moſt the third part of an inch when at their full growth. Breaking of their webs avail but little, for they are woven again by the next day: for which reaſon ſome have been of opinion, that it is beſt to let them enjoy undiſturbed the ſurface of the corn of which they have taken poſſeſſion. But it ſhould be conſidered, that three inches are a ſixth part, and four inches upwards of a fifth, of any quantity of corn ſpread eighteen inches deep, which is the medium thickneſs at which it is laid; and that, independant of the bad ſmell with which the reſt is tainted, this is a very conſiderable object, though it extend no farther. When this cruſt is broken, moſt of the grains which compoſe it are found to be either gnawn in their inſide, or full of live worms, or of aureliæ, according to the ſeaſon; or one ſees only the empty ſheaths of the caterpillars, if the aureliæ have been transformed into moths.

It is ſaid, that ſtrewing the corn with powdered lime, ſo as to form a cruſt over it, will preſerve it from the ravages of theſe inſects: but as the ſurface would ſtill be ſpoiled, and as that ſurface may be a conſiderable part of the ſmall proviſion of wheat allotted for a family only, M. Duhamel did not try this expedient. Covering it with hay, which he did try, anſwered no end whatever.

Theſe obſervations, and the reflections conſequent thereon, made him ſuſpect that this inſect, as it delights in none but very warm places, would not be able to live in the cold air of his ventilating granaries.

Accordingly, in the winter of the year 1746, he collected all the wormy cruſts which theſe caterpillars had formed in his common granaries, where they were very thick, the moths having been extremely numerous the preceding ſummer. Theſe cruſts were broken and ſcreened; and what grain could be got from them, which undoubtedly was impregnated with the eggs of the moths, was put into one of his granaries of preſervation, which contained ſeventy-five cubic feet, and was ventilated from time to time during all the winter.

Towards the end of May, when the vent-holes at the top of this granary were opened, a prodigious number of moths flew out, which ſhewed that they did not like their ſituation.

When the wheat was thought to have been ventilated ſufficiently, the holes were ſhut cloſe, and nothing more was done to it for a month: for as this corn (which had not been ſtove-dried) was old and dry enough, it was but ſeldom ventilated.

In June 1747, this granary was emptied: all the moths and worms were dead, and there remained only a thin cruſt, not above a twelfth part of an inch thick, on the top of the corn, which had ſo far loſt the bad ſmell it had when put into the granary, that it ſold for the current market price.

Not ſatisfied with this ſingle method, M. Duhamel tried the effect of the ſtove upon another parcel of wheat known to be full of theſe worms. A heat from 45 to 50 degrees of Réaumur's thermometer (from 115 to 124 of Farenheit's) killed them all. This corn was then laid up in a common granary, where it remained two years without being attacked by any of theſe moths; and even in the third, but very few of them appeared.

Theſe experiments remove all doubt of the poſſibility of deſtroying the corn moth, or worm, without hurting the grain, which would otherwiſe be ſpoiled by it; and as that grain, generally is wheat, which the inſect prefers to any other, this diſcovery is of great importance to the huſbandman, as well as to the public.

MOULD, a looſe kind of earth, every where obvious on the ſurface of the ground, called by ſome mother earth, and by others loam.

The goodneſs of a mould for the purpoſes of agriculture and gardening, &c. may be known, according to Mr. Miller, by the ſight, ſmell, and touch. 1. Thoſe moulds that are of a bright cheſnut or hazely colour, are counted the beſt: of this colour are the beſt loams, and alſo the beſt natural earth; and this will be the better yet, if it cut like butter, and does not ſtick obſtinately, but is ſhort, tolerably light, breaking into ſmall clods, is ſweet, will be tempered without cruſting or chopping in dry weather, or turning to mortar in wet. Next to that the dark grey and ruſſet moulds are accounted the beſt: but the light and dark aſh coloured the worſt, ſuch as is uſually found on common heathy ground: the clear tawney is by no means to be approved; but that of a yellowiſh red colour is the worſt of all: this is commonly found in wild and waſte parts of the country, and for the moſt part produces nothing but goſs, furze, and fern, according as their bottoms are more or leſs of a light and ſandy, or of a ſpewey gravel, or clayey nature. 2. All lands that are good and wholeſome, will, after rain, or breaking up by the ſpade, emit a good ſmell. 3. By the touch we may diſcover whether it conſiſts of ſubſtances entirely arenaceous, or clammy; or, as it is expreſſed by Mr. Evelyn, whether it be tender, fatty, deterſive, or ſlippery; or more harſh, gritty, porous, or friable.

MOULDINESS, a term applied to bodies which corrupt in the air, from ſome hidden principle of humidity therein; and whoſe corruption ſhews itſelf by a certain white down, or lanugo, on their ſurface, which, viewed through a microſcope, appears like a kind of meadow, out of which ariſes herbs and flowers, ſome only in the bud, others full blown, and others decayed, each having its root, ſtalk, and other parts.

MOUND, a bank or fence of earth. *See the article* BANK.

MOW, the pile or collection of corn in the ſtraw, placed in a bay of a barn. *See the article* BARN.

MOW-BURNT, over-heated in the mow for want of being dry.

MOWING, the art of cutting down corn, graſs, &c. with a ſcythe.

M. de L'Iſle lately introduced the mowing of wheat. The method is this: the ſcythe he uſes is at leaſt ſix inches ſhorter in the blade than the common ſcythe, and inſtead of a cradle has two twigs of ozier put ſemicircular-wiſe into holes made in the handle of the ſcythe, near the blade, in ſuch a manner, that one ſemicircle interſects the other: this method is frequently practiſed by the men who mow our meadows, as they think a cradle unneceſſary and cumberſome, unleſs the ſcythe is to carry over a large and very heavy ſwarth.

In mowing barley, or oats, the corn is always on the right-hand of the workman: but by M. de L'Iſle's method of mowing wheat the corn is at his left-hand: he mows it inward, bearing the corn he cuts on his ſcythe, till it comes to that which is ſtanding, againſt which it gently leans. After every mower follows a gatherer, which may be a lad of twelve or fourteen years of age, or a woman. The gatherer keeps within five or ſix feet of the mower, and being provided either with a hook or ſtick about two feet long, gathers up the corn, makes it into a gavel, and lays it gently on the ground: this muſt be done with ſpirit, as another mower immediately follows; for to every mower there is a particular gatherer.

To do this work properly, the mower ſhould form but one track with his feet, advancing in a poſture nearly as if he was going to fence, one foot chaſing the other. In this manner the ſtanding corn is mowed; but the workman muſt take care to have the wind at his left, as it bears the corn towards the ſcythe, and cauſes it to be cut nearer the ground. If the wind is behind the mower, it is no great inconvenience: it only occaſions the ſcattering of a few ears; and the cut corn, which ſhould lean againſt the ſtanding corn, is ſometimes thrown down; which makes the work go on ſlower, and encreaſes the gleanings. The wind in front is very bad; the corn cannot be cut cloſe, and there is a great loſs: but the wind on the right-hand is worſt of all; the ſtubble is left long, and ſuch a quantity of gleanings, that one would imagine no crop had been taken off. When wheat is bent, the workman takes the corn as it preſents itſelf to him, which has the ſame effect as if the wind was at his left-ſide. When wheat is laid, it is more troubleſome to the gatherer, becauſe the cut corn is apt to be mixed with that which is ſtanding; but a good mower takes the advantage of the wind, and cuts it againſt the way it is laid. No particular directions can be given for corn that is lodged and tangled, unleſs it is to take it as it is inclined, as if the wind was in the back of the mower.

This method of mowing wheat was tried in Northamptonſhire, and the following account of it ſent to the editors of the Muſeum Ruſticum.

"A gentleman, a foreigner, ſays this writer, came down here to a neighbour's of mine, in order to put us into a method of going about this work.

"Many trials were made in the preſence of myſelf, and a great number of others: the ſcythes did their work well; they cut the corn within two inches of the ground: and though our workmen were of courſe a little aukward, ſcarcely any ears were ſcattered: but the greateſt advantage is, that a man with one of theſe ſcythes can cut down at leaſt double the quantity of wheat in the day he can with a ſickle or hook.

"The chief objections made to the introduction of this method were, that the ſtubble is left too ſhort, and on that account is not fit for thatching; that the weeds are cut with the corn, and will be apt to mould or heat, and the ſeeds to mix with the corn in threſhing; and that the poor are deprived of their gleanings, as none of the corn is ſcattered.

"But theſe objections muſt ſoon fall to the ground, when we reflect that, by mowing, the ſtraw is much longer, and certainly ſtraw is much better for thatching than ſtubble.

As to the weeds being cut with the corn, it is of no conſequence; for they are eaſily ſhaken out of the bottoms of the ſheaves, after drying a day or two; and the ſheaves may be ſafely left to dry, if they are laid in the following manner.

"Suppoſe three tobacco pipes to repreſent three ſheaves, the bowls to be the feet of the ſheaves, and the ſmall part the ears: lay one of theſe on the ground; then take another, and lay the bowl of it under the ſmall end of the firſt; take afterwards a third, and diſpoſing them in form of a triangle, lay the bowl of the third under the ſmall end of the ſecond, and the bowl of the firſt under the ſmall end of the third: by diſpoſing them in this form, the ears are always kept from the ground, and will endure a great deal of wet without damage.

"As to the ſeeds of the weeds being threſhed, and mixing with the corn, that may eaſily be avoided; for the wheat, by this method of mowing it, is ſo regularly diſpoſed in the ſheaf, that the ſheaves need only to be threſhed on the ear, without being unbound.

"The objection, that the poor would be deprived of their gleaning, is a mere farce: their time might be much better employed; and by the ſame parity of reaſon, the more corn the farmer left for them in the field, the more juſtice he would do them; and this few would venture to aſſert, as cuſtom might in time extend it to half the crop: beſides, as by this new method, a great deal more corn will be inned, it will of courſe be cheaper the year round, and eaſier purchaſed by the poor.

"The foreign gentleman was of great uſe to us: he is intelligent and communicative, and we all of us acknowledge ourſelves much obliged to him.

"Many in this county propoſe making more extenſive trials of it next harveſt, and there is no doubt but that in the ſpace of a few years it will be brought into conſtant uſe.

"A ſhort certificate of the advantages reſulting from the practice of this method, was ſome time ago drawn up: it was preſently ſigned by a number of gentlemen, farmers, gardeners, labourers, &c. and tranſmitted to Dr. Templeman, ſecretary to the Society of Arts in London, to be, if neceſſary, publiſhed for the benefit of the kingdom. This new method will doubtleſs be introduced to the knowledge of the Engliſh world with a better grace, coming under the ſanction and recommendation of ſo reſpectable and uſeful a Society."

The authors are happy, that, as members of the ſociety, they have an opportunity of conveying to the readers of this Dictionary, a perfect idea of the form of the ſcythes

lately tried in Northamptonſhire: for this purpoſe they have annexed a plate engraved from a drawing taken from the three ſcythes now depoſited in the Society's machine-room, for the inſpection of the curious. The parts are repreſented ſeparate, that they might be more diſtinct: the dimenſions and proportions follow. Plate XX. Fig. 7. is the handle, or mounting of the largeſt ſcythe: the length of it from *a* to *c* is eight feet, from *a* to *b* five feet, from *b* to *c* three feet: at *c* is the part whereon the blade is fixed, *d* ſhews the two bends which ſerves inſtead of a cradle. Fig. 3, is the blade to this ſcythe: from the heel *a*, to the point *b*, meaſures three feet, and it is two inches and a half broad: when the ſcythe is mounted, from the point of the blade *b*, to the end of the long handle *a*, meaſures an angle of ſeven feet. Fig. 4. is the blade of an other ſcythe, the length and breadth the ſame as the laſt blade. Fig. 5. is the handle to this ſecond ſcythe: from *a* to *d*, it meaſures three feet ten inches, from *a* to *b*, two feet, and from *b* to *c*, one foot ſeven inches: the blade is fixed at *a*, and when the ſcythe is mounted, the angle from the point of the ſcythe-blade to the end of the handle, meaſures three feet nine inches. Fig. 6. is the blade of the ſmalleſt ſcythe: from *a* to *b*, it meaſures one foot nine inches, and is two inches and a half broad. Fig. 7. is the handle or mounting to this laſt ſcythe: at *a* the blade is fixed: from *a* to *b* is one foot five inches and a half; the angle from *b* to *c*, four inches and a half; from *c* to *d*, five inches; from *d* to *e*, three inches and three quarters. Fig. 8. is the gathering-hook: the length of its handle, from *a* to *b*, is three feet nine inches; the hook from *b* to *c*, is ten inches long.

MUCK, dung, or ſtraw that lies rotting.

MUD, the ſediment at the bottom of rivers, ponds, ditches, &c. *See the article* DUNG.

MUGWORT, a very troubleſome weed; for its roots creep far under the ſurface of the ground, ſo as ſoon to overſpread a large ſpace, if they are not ſtopped; and its ſeeds, being light, and eaſily carried to a diſtance by the wind, will produce numbers of new plants the next ſpring. It has plain cut leaves, ending in many parts, woolley underneath, and ſingle ſpikes of pale yellow oval flowers, which blow in June.

MULBERRY, the name of a tree, of which there are ſeveral ſpecies, but two only are generally cultivated, called the black and white mulberry.

The black mulberry grows naturally in Perſia, from whence it was firſt brought to the ſouthern parts of Europe; but is now become common in every part of Europe, where the winters are not very ſevere: for in the northern parts of Sweden, theſe trees will not live in the open air; and in ſeveral parts of Germany they are planted againſt walls, and treated in the ſame way as peach and other tender fruits are here.

Theſe trees are generally of both ſexes, having male flowers or katkins, on the ſame tree with the fruit; but it often happens, that ſome of the trees which are raiſed from ſeeds, have only male flowers, and produce no fruit; ſo that thoſe who plant theſe trees for their fruit, ſhould never make choice of ſuch as have been propagated by ſeeds, unleſs they have ſeen them produce fruit in the nurſery. It is alſo the ſureſt way to mark ſuch trees as are fruitful in the nurſery, at the time when their fruit is upon them, becauſe thoſe trees which are propagated by layers, are ſometimes of the male ſort.

The old mulberry trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; ſo that where there are any of theſe old trees, it is the beſt way to propagate from them, and to make choice of thoſe branches which are moſt fruitful. The uſual method of propagating theſe trees, is by laying down their branches, which will take root in one year, and are then ſeparated from the old trees; but as the moſt fruitful branches are often ſo far from the ground as not to be layed, unleſs by raiſing of boxes or baſkets of earth upon ſupports for this purpoſe; ſo the better way is to propagate them by cuttings, which, if rightly choſen and ſkilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a diſtance, and from the moſt fruitful branches. Theſe cuttings ſhould be the ſhoots of the former year, with one joint of two years wood to their bottom; the cuttings ſhould not be ſhortened, but planted their full length, leaving two or three buds above ground. The beſt ſeaſon for planting them is in March, after the danger of hard froſt is over; they ſhould be planted in light rich earth, preſſing the ground pretty cloſe about them; and if they are covered with glaſſes, it will forward their putting out roots; but where there is no ſuch conveniency, the ground about them ſhould be covered with moſs, to prevent its drying; and where this is carefully done, the cutting will require but little water, and will ſucceed much better than with having much wet. If the cuttings ſucceed well, and make good ſhoots, they may be tranſplanted the following ſpring into a nurſery, where they ſhould be regularly trained to ſtems, by fixing down ſtakes to each, to which the principal ſhoots ſhould be faſtened; and moſt of the lateral branches ſhould be cloſely pruned off, leaving only two or three of the weakeſt to detain the ſap, for the augmentation of the ſtem; for when they were quite diveſted of the ſide ſhoots, the ſap is mounted to the top, ſo that the heads of the trees grow too faſt for the ſtems, and become too weighty for their ſupport. In about four years growth in the nurſery, they will be fit to tranſplant where they are to remain; for theſe trees are tranſplanted with greater ſafety while young, than when they are of a large ſize.

The white mulberry is commonly cultivated for its leaves to feed ſilk-worms, in France, Italy, &c. though the Perſians always make uſe of the common black mulberry for that purpoſe; and it is ſaid that the worms fed with thoſe of the black produce much better ſilk than thoſe fed with the white; but it is to be obſerved, that the leaves of the black ſort ſhould never be given to the worms, after they have eaten for ſome time of the white, leſt the worms ſhould burſt, which is often the caſe when they are thus treated.

The trees which are deſigned to feed ſilk-worms ſhould never be ſuffered to grow tall, but rather kept in a ſort of hedge; and inſtead of pulling off the leaves ſingly, they ſhould be ſheared off, together with their young branches, which is much ſooner done, and not ſo injurious to the tree.

This white ſort may be propagated either from the ſeeds or layers, as the black mulberry, and is equally hardy; but the moſt expeditious method of raiſing theſe trees in quantity, is from the ſeeds, which may be procured in plenty from the ſouth of France and Italy. The beſt way to ſow theſe ſeeds, in England, is to make a moderate hot-bed, which ſhould be arched over with hoops, and

covered

covered with mats; upon this bed the ſeeds ſhould be ſown in the middle of March, and covered over with light earth about a quarter of an inch deep: in very dry weather, the bed muſt be frequently watered, and in the heat of the day ſhaded with mats, and alſo covered in the nights when they are cold. With this management the plants will come up in five or ſix weeks, and as they are tender when they firſt appear, ſo they muſt be guarded againſt froſty mornings, which often happens in May. During the ſummer they muſt be kept clean from weeds, which is all the culture they require: but there muſt be care taken of them the firſt winter, eſpecially to cover them in autumn, when the firſt froſts come, which will kill the tender plants to the ground, if they are not protected; the following March, theſe plants ſhould be tranſplanted into the nurſery, to get ſtrength, where they may remain two or three years, and then ſhould be removed where they are to continue.

MULE, a mongrel kind of quadruped, uſually generated between an aſs and a mare, and ſometimes between a horſe and a ſhe-aſs.

The mule is a ſort of a monſter, of a middle nature between its parents, and therefore incapable of propagating its ſpecies; ſo careful is nature to avoid filling the world with monſters. Mules are chiefly uſed in countries where there are rocky and ſtony roads, as about the Alps, Pyrenees, &c. Great numbers of them are kept in theſe places; they are uſually black, ſtrong, well limbed, and large, being moſtly bred out of the fine Spaniſh mares.

In Spain there is great encouragement for breeding and training mules to every kind of buſineſs: in Portugal they are eſtimated at a high price, and are not a little valued in the ſouthern parts of France.

I own, ſays a writer in the Muſeum Ruſticum, I have often been aſtoniſhed (the uſeful nature of this creature conſidered) that we do not more encourage the breed in England. This inattention may perhaps proceed from mules being thought naturally more vicious than horſes: I doubt the fact; yet be it as it will, they are, to my knowledge, equally capable of being made uſeful, docile, and gentle.

I aſſert not this merely from opinion, having had many years experience of what may be done in this way.

During the courſe of the war, in which his royal highneſs the duke of Cumberland commanded the army of the allies in Flanders, the empreſs queen made him a preſent of above fifty fine mules to carry his baggage: theſe mules, at the end of that war, were brought to England, at which time I had an opportunity of ſeeing and admiring them. They were, I think, the fineſt and largeſt I ever before beheld; and one, nearly white, particularly attracted my attention, being almoſt ſixteen hands high.

This circumſtance of ſeeing his highneſs's ſtring of mules, it was firſt induced me to think of breeding them, in which I have ſince had uncommon ſucceſs.

I had many encouragements to make the attempt: my fortune was ſuch as could not be hurt by the experiment; my park was extenſive, and very proper for the purpoſe; and I had many ſervants, who had ſo little to do, as to have leiſure time enough to obey my orders in this matter.

My great difficulty at firſt ſetting out was to procure a he aſs or two to cover my mares; for I found none were to be got of any ſize bred in England.

It is true, I met with ſome Spaniſh aſſes; but they were ſluggiſh, and not likely to get mettled colts: beſides, I, could not buy two of them, of any ſize and ſhape, under ſeven hundred pounds, which I thought too much money to throw away, if I could by any other means get my end eaſily anſwered.

Senſible that perſeverance does much in all things, I bought a ſtrong-boned, fine-ſhaped he aſs, and two ſhe aſſes of a large ſize, conſidering they were bred in England, determined to try if I could not by a little care and attention mend the breed, before I attempted to get any mules.

Theſe coſt me only four pounds, and my two ſhe aſſes ſoon afterwards dropped a foal each.

I continued to breed from them ſeveral years; but it is the manner in which I managed the aſs colts, that the great ſucceſs I have lately had in breeding mules muſt be aſcribed.

I took care that the ſhe aſſes ſhould be well fed, and be kept in order, both before they dropped their foals, and afterwards whilſt they ſuckled.

As ſoon as the colts were weaned, I had them as carefully attended and fed as if they had been got by Childers or Babram: every winter they ſtood under cover, defended from the injuries of the weather, and were regularly fed, cleaned, and littered, the door of the ſtable being always left open two or three hours in the middle of the day, for them to exerciſe themſelves as they thought proper, which they ſeldom failed to do, if the weather was fine, to ſome purpoſe, returning, without compulſion, when the hour of feeding approached.

In this manner I always managed them till they were three years old, when I permitted my ſtone colts to cover, and my females to breed.

You would indeed be ſurpriſed to ſee how much, by this plain and ſimple management, my breed of aſſes is improved; for I have now in my ſtables ſeveral he aſſes, which I keep as ſtallions, that are, I believe, as large, and as well ſhaped, as any that were ever heretofore bred in theſe iſlands.

I ſhall now proceed to deſcribe to you the manner in which I breed my mules. For this purpoſe I chuſe mares that are of a very large breed, ſuch as are ſometimes uſed to draw the brewers drays in London.

My next care is that they are young, full of life, large barrelled, but ſmall limbed, with a moderate ſized head, and a good forehand. At the proper ſeaſon my mares are covered by my aſs ſtallions, and they ſeldom miſs. During the time the mares are in foal, I take care to have them fed with nouriſhing fodder, ſuch as I imagine will moſt contribute to the ſize of the foal.

My expectations, after this management, are generally anſwered, for in due ſeaſon my mares drop foals, which I could often ſell for ten, and ſometimes for twenty guineas a piece at three months old; and their future value is more than in proportion encreaſed afterwards.

I always houſe my mule colts the firſt winter; otherwiſe the hard froſts, and ſharp, cold, long nights, would ſtint them in their growth, beſides making them unſhapely and rough.

From the time of their being dropped, I cauſe them often to be handled, to make them gentle: this prevents their hurting themſelves by ſkittiſhneſs, and ſudden frights; they are beſides much eaſier broke at the proper age, and become

become docile and wonderfully harmleſs, having nothing of that viciouſneſs which is ſo commonly complained of in theſe animals.

I have them for the moſt part broke at three years old, but never permit them to do much work till four: they are thus ſecure from being hurt by hard labour, till they have acquired ſtrength enough to bear it without injury.

I have now ſeveral mules which I conſtantly employ in various kinds of labour; two, which are indeed very fine, I ride myſelf after my harriers; two more I keep for my huntſman, and one for my whipper-in: theſe are black, ſorrel, and grey.

I have alſo four fine mules, but ſtronger and heavier than thoſe above-mentioned, which I drive occaſionally in a four-wheel chaiſe, beſides ſeveral others leſs valuable, uſed for ploughing and carting.

Some of my neighbours ſmile at my taſte; yet they cannot at the ſame time help acknowledging, that they are cheaper animals, when bred at home, as has been my practice, than horſes.

Perhaps ſome of your readers, from the hints above thrown out, may be inclined to try the experiment: if ſo, I would caution them againſt ſome errors I at firſt ſetting out fell into.

I thought at firſt I could not keep my colts too well during the winter months: accordingly I ordered that they ſhould have the ſweeteſt hay, which I had before ordered to be reſerved for my cows, and as many oats as they could eat.

This way of feeding them, it is true, made them very fat; but it was far from being an advantage to them; for I afterwards found by experience, that it was not only incurring a much larger expence than was any ways neceſſary, but alſo made them wonderfully nice and delicate in their appetites ever after, and alſo by encreaſing their weight of fleſh, made them more ſubject to ſtrains and hurts in their morning gambols.

Finding this to be the caſe, I altered my method entirely, and contented myſelf with giving them food enough to prevent their loſing fleſh, and keep up their growth, without palling their appetites with delicacies, or making them over fat: as to the reſt, I took the ſame care of defending them from the injuries of the weather as ever, by allowing them ſtable room, and good litter to ſleep on, beſides cauſing them every day to be well rubbed down with a hard wiſp of ſtraw by an active groom, whoſe peculiar province it was to attend them; and this was ſcarcely ever omitted, particularly in cold, raw, wet weather, when they were leaſt inclined to exerciſe themſelves in the park. *Muſeum Ruſticum, vol.* II. *pag.* 162.

MULCH, ſtraw half rotten.

MULLOCK, dirt, or rubbiſh.

MULLEIN, the name of a biennial plant, which periſhes ſoon after it has perfected its ſeeds. The leaves ſpread on the ground, are nine or ten inches long, and ſix broad, very woolly, of a yellowiſh white colour, and very little footſtalk. The ſtem riſes four or five feet high, and the upper part of it is garniſhed with yellow flowers, which ſit very cloſe, and form a thick ſpike. Theſe flowers have an agreeable odour, appear in July, and the ſeeds ripen in autumn.

This plant commonly grows by the ſides of highways, and on banks: but if it once gets into the fields in a warm expoſure, and is ſuffered to ſeed there, it will ſoon overrun the whole ground. It may be eaſily deſtroyed by cutting off the ſtem, when it is in flower.

MURE, the cake of apples, grapes, &c. left in the preſs, after extracting the juice.

MURRAIN, or *Gargle*, a contagious diſeaſe among cattle.

The moſt remarkable murrain is that mentioned in the Philoſophical Tranſactions, which ſpread through Swiſſerland, Germany, into Poland, &c.

The contagion ſeemed to propagate itſelf in form of a blue miſt, which fell on the graſs where the cattle grazed, when whole herds, forbearing their food, almoſt died away in twenty-four hours. Upon diſſection were found large corrupted ſpleens, ſphacelous and corroded tongues, &c. And even the perſons who managed them were infected, and died like the beaſts.

Some imagined it had its riſe from noxious vapours thrown out of the earth, in three earthquakes perceived in the neighbourhood of the place where it began; though Dr. Slare thinks it rather owing to ſwarms of volatile inſects.

The antidote for the ſound, and medicine for the ſick, was equal parts of ſoot, gunpowder, brimſtone, and ſalt, with as much water as would waſh it down: a ſpoonful was the doſe.

The common ſigns of this diſeaſe are a hanging down of the head, gum at the eyes, as big as your finger, growing weakly, ſtaggering, the head ſwelling very much, the breath ſhort, the heart beating with rattling in the throat; and if you put your hand into the creature's mouth, and find his breath very hot, and his tongue ſhining, the diſtemper is very ſtrong.

As ſoon as you find any of your cattle infected, take a pretty large quantity of blood from them immediately, and give them a drench. Madder root is highly commended for this diſtemper.

MUSHROOM, a genus of imperfect plants, compoſed of a pedicle crowned with a broad head, convex and ſmooth at the top; and hollow, foliated, lamellated, or piſtulous underneath.

It is of the utmoſt importance to diſtinguiſh the right eatable ſort, from ſeveral noxious kinds that have been productive of even fatal accidents: the true ſort appears at firſt with a roundiſh head, not unlike a button. The outſide of this head is then very white, as is likewiſe the ſtalk on which it grows; but its under part, when it is taken off that ſtalk, from which it ſeparates pretty eaſily, is of a livid fleſh colour. Its fleſh is alſo very white within. If this ſort remains undiſturbed, its head will ſpread to a conſiderable ſize, and open at the bottom, ſo as to form an almoſt flat ſurface, the under part of which will then be changed to a dark colour.

Moſt of the writers upon gardening have ſpoken ſo confuſedly, not to ſay, of moſt of them, ſo unintelligibly, of the means of propagating this plant, that excepting the authors of the *Maiſon Ruſtique*, and Mr. P. Miller, one is ſometimes puzzled to gueſs at their meaning. The account which this laſt has given in his Dictionary, is the moſt practical, being the method of the gardeners near London, who raiſe annually great quantities of muſhrooms for ſale. The ſubſtance of it is to the following effect.

The ſpawn of muſhrooms, from which only they are propagated, looks like a white mouldineſs ſhooting out in long ſtrings. It is frequently found among the dung of old

old hot-beds, or in old dunghills, eſpecially when much litter has been mixed with theſe laſt, or the wet has not penetrated ſo as to rot it; or it may be procured by mixing ſome long ſtable dung, which has not been thrown up in a heap to ferment, with ſtrong earth, and then laying this mixture under cover, where it cannot be wet, and where the air may be excluded from it as much as poſſible; for, the more effectually it is kept from air, the ſooner the ſpawn will be produced. It will generally appear in about two months, if the heap has not been laid ſo cloſe together as to heat (for that will deſtroy the ſpawn) and eſpecially if it has been well covered with old thatch, or litter which has lain ſo long abroad as to have loſt the power of fermenting. Theſe are expedients by which the ſpawn of muſhrooms may be procured at almoſt any time, by thoſe who have not already had muſhroom-beds in their gardens, and therefore cannot collect it from their remains: for there are but two months of the year in which it can be gathered from downs or paſtures. Theſe are Auguſt and September; when plenty of muſhrooms ſpring up naturally in many of thoſe places. To propagate them from thence, the ground ſhould be opened about their roots, and ſuch earth as is there found full of ſmall white knobs, which are the offſets, or young muſhrooms, ſhould be attentively gathered up, with as much care as can be not to break the lumps, or the earth about them. This ſeed, or rather this ſpawn (for if muſhrooms have ſeeds, they are imperceptible to the eye) ſhould be kept very dry till it is uſed: for the drier it is, the better it will take to the bed, as has been remarkably experienced by Mr. Miller, who declares, that he never ſaw theſe plants produced ſo ſoon, or in ſo great quantity, as from a parcel of their ſpawn which had lain near the oven of a ſtove for upwards of four months, and was become ſo dry, that he deſpaired of its ſucceſs.

The beds for muſhrooms ſhould be made of dung plentifully intermixed with litter, but not thrown in a heap to ferment. The beſt dung for this purpoſe is that which has lain ſpread abroad for a month, or longer. Their breadth ſhould be about two feet and a half at bottom, their length proportioned to the deſired quantity of muſhrooms, and they ſhould be made on dry ground, by ſpreading upon it, firſt a layer of dung about a foot thick, and upon this about four inches deep of ſtrong earth; then a couch of dung about ten inches thick, and upon that another layer of earth, contracting the ſurface of the bed all the way up, till it terminates like the ridge of a houſe. This may be done with three layers of dung, and as many of earth. When it is finiſhed, it ſhould be covered with litter, or old thatch, as well to prevent its drying, as to keep out wet, and after it has remained eight or ten days in this ſituation, it will be of a proper temperature to receive the ſpawn, for which its warmth ſhould be but moderate. The thatch, or litter, ſhould then be taken off, the ſides of the bed ſhould be ſmoothed, and a covering of light rich earth, by no means wet, ſhould be laid all over it, about an inch thick. Upon this the ſpawn ſhould be placed, by laying its lumps about two or three inches aſunder, in ſuch manner as to prevent their ſlipping down, and then the whole ſhould be covered gently with about half an inch thick of the ſame light earth as was uſed before. The covering of litter ſhould then be replaced over the bed, ſo thick as to ſecure it from wet, and to prevent its drying. If theſe beds are made in the ſpring or autumn, when the weather is temperate, the muſhrooms will frequently come up in a month's time: but thoſe which are made in ſummer, when the ſeaſon is hot, or in winter, when it is cold, will not produce them near ſo ſoon. Sometimes too it happens that neither of theſe beds, but moſt particularly thoſe made in the ſummer or winter, yield any muſhrooms before the end of five or ſix months; and that they then produce uncommon quantities, and continue in perfection for a long time.

The great art in managing of theſe beds is, to keep them conſtantly in a due degree of moiſture, and, above all, not to ſuffer them ever to receive too much wet; for that would inevitably deſtroy the ſpawn of the muſhrooms. During the ſummer, they may be uncovered, to admit gentle ſhowers of rain to them at proper times; and if the weather continues dry for a long while together, it will be right to water them gently now and then, but by no means to overdo it. During the winter, they muſt be kept as dry as poſſible, and cloſely covered, leſt the cold air of the ſeaſon ſhould injure them. It will even be right in froſty or very cold weather, to lay over them a covering of dry litter, for it muſt not incline to ferment, and upon that ſome warm litter ſhaken from out of a heap of dung. This covering ſhould alſo be renewed as often as it is found to decay, and, if the cold grows more ſevere, its thickneſs ſhould be increaſed.

The muſhrooms thus produced have a finer flavour than any that are gathered in the fields; and if the above directions are obſerved, they may be had in plenty during the whole year: for each ſingle bed will continue good for ſeveral months, and yield great quantities if the ſpawn takes kindly.

When theſe beds are deſtroyed, the ſpawn for a freſh ſupply ſhould be taken from them, and laid up in a dry place till the proper ſeaſon for uſing it, which ſhould not be ſooner than five or ſix weeks, in order that it may have time to dry well, before it is put into the new bed; for otherwiſe there will be ſome danger of its ſucceeding.

MUST, new wine, or wort, before it is fermented.

MUSTARD is an annual plant raiſed from its ſeed only. The white muſtard, as it is commonly called, is the ſort chiefly cultivated in gardens, for a ſallad herb in the winter and ſpring. The ſeeds of this are ſown very thick in drills, either upon a border warmly ſituated, or if the weather be very cold, upon a gentle hot-bed, in the ſame manner as creſſes and other ſmall ſallading, and in about ten days or a fortnight after the time of ſowing, the plants will be fit for uſe; for when they are large and have rough leaves, they are too ſtrong to be mixed with ſallads.

The beſt way to ſave the ſeeds of this plant, is to ſow a ſpot of ground with it in the ſpring, to thin the plants when they have about four leaves, and at the ſame time to hoe down the weeds, as is practiſed for turnips. This hoeing is to be repeated in about a month after, and the plants are then to be left about eight or nine inches aſunder, which will be a ſufficient ſpace for the growth of this ſpecies. If theſe hoeings are well performed, in dry weather, they will keep the ground clean till the muſtard ſeeds are ripe. The ſtalks of this plant, which are branched and hairy, will then be about two feet high, and the ripening of its ſeed is indicated by the pods changing to a brown colour; immediately after which they ſhould be cut down, dried upon cloths, for two or three days, and then threſhed out for uſe.

The larger ſorts of muſtard, the ſeeds of which are uſed chiefly for ſauce, are to be treated in the ſame manner; excepting that, as they grow much larger, a proportionably greater ſpace muſt be left between their plants; and as their ſeeds will not ripen ſo ſoon as thoſe of the ſmaller kind, three hoeings, or rather good deep ſtirrings, of the ground may be requiſite for them. One of theſe large ſorts, which is the common muſtard, grows naturally in many parts of England; but is cultivated in the fields for its ſeeds, of which the ſauce called muſtard is made; and another ſort, which naturally grows in our arable lands, and is alſo cultivated for uſe, produces the ſeeds which are commonly ſold under the appellation of Durham muſtard-ſeed. The ſtalks of the laſt ſort ſeldom riſe above two feet high; but thoſe of the former generally run up to the height of four or five feet.

N.

NAIL, or *Naile*, the weight of eight pounds.

NAPE, or *Neap*, a piece of wood with two or three feet, with which they ſupport the fore-part of a loaded wain.

NASTURTIUM. *See the article* CRESS.

NAVE *of a Wheel*, is that ſhort thick piece in the center of the wheel, which receives the end of the axletree, and in which the ends of the ſpokes are fixed; it is bound at each end with hoops of iron, called the nave-bands; it has likewiſe, in each end of the hole, through which the end of the axletree goes, a ring of iron, called the wiſher, which ſaves the hole of the nave from wearing too big.

NEAT, black cattle, oxen.

NETTLE, the name of a weed well-known, and which may be eaſily deſtroyed by cutting the roots, before the plant has perfected its ſeed.

NEWING, yeaſt, or barm.

NICKING, the name of an operation often performed on the tails of ſaddle-horſes, and by which means they carry them in a more beautiful manner.

Before we deſcribe the operation of nicking, it may be neceſſary to enquire how the effect of it (the elevation of the tail) is brought about; and in order to know this, and judge with propriety of the operation, we muſt conſider the tail as elevated, or lifted up, by one ſet of muſcles, and depreſſed or pulled down by another.

It is ſomewhat remarkable, that Snape, Saunier, and Gibſon, who are in general pretty exact in their anatomical deſcriptions, ſhould omit, in their account of the muſcles of a horſe, to deſcribe thoſe of the tail: for which reaſon, as a proper opportunity has not offered, to ſupply this omiſſion, by making a complete diſſection, with that accuracy we could have wiſhed, it is hoped the ſubſequent imperfect deſcription will be excuſed, as it was taken only from a tail that was diſſected after docking.

Here we obſerved, that the muſcles which elevate the tail, are more numerous, large, and ſtrong, than thoſe that depreſs it; that they are cloſely connected to the bones of the tail by fleſhy fibres, and terminate in ſtrong tendons at the extremity: but the muſcles of the latter ſoon form into tendinous expanſions, and beſides three large tendons, which are inſerted into the latter bones of the tail, there are ſeveral other ſmall tendons, which run laterally, whoſe uſe moſt probably is to move the tail ſideways. The arteries are four in number, and run ſometimes above the bones of the tail, conſequently eaſily avoided by a dextrous hand, as they cannot readily be wounded by the knife, in dividing the tendons neceſſary to be cut in this operation.

The art of nicking horſes then chiefly conſiſts in a tranſverſe diviſion of theſe depreſſing tendons of the tail, and ſuch a poſition afterwards as will keep their extremities from coming again into contact; ſo that an intervening callus fills up the vacuity: by theſe means an additional power is given to the antagoniſt muſcles, viz. the elevators; the counteraction of the depreſſors being manifeſtly abated by the diviſion of the tendons, and the intervention of the callus.

The uſual method of ſupporting the tail by a pulley and weight, is liable to many exceptions, the extremities of the divided tendons not being by that method kept ſufficiently aſunder; the ſituation of the tail being rather inclined to a perpendicular than a curved direction: this poſition too is liable to many variations, from the different movements of the horſe, and is the reaſon that the tail frequently inclines to one ſide, as the nick may heal up faſter on one ſide than the other; the diſagreeable ſituation the horſe muſt ſtand in, with a weight conſtantly hanging to his tail, is another material objection, beſides the neceſſity of removing it when the horſe is exerciſed, or taken out to water.

To remedy theſe inconveniencies, and perfect this operation, a very ingenious gentleman, who had thoroughly conſidered it, has been ſo kind as to favour us with a draught and deſcription of a machine he contrived for that purpoſe, which has frequently been practiſed with the expected ſucceſs, and indeed at firſt view appears in every reſpect calculated to correct all the defects in the old one:

as

as we doubted not its reception being perfectly agreeable to the public, we have ordered a plate to be engraved, which, with the annexed deſcription, will, we hope, make it very familiar and intelligible to every capacity.

In regard to the operation, it is worth notice, that the extremities of the tendons, which jut out in the operation, need not here be cut off, as is cuſtomarily done; the number of the inciſions muſt be in proportion to the length of the tail, but three in general are ſufficient. The moſt approved method of dreſſing at firſt, is with powdered roſin, and ſpirit of wine, applying a ſoft doſſil of lint or tow, dipped in the ſame, between each nick, and lapping the tail up with a linen cloth and broad fillet; which the next morning ſhould be cut open down the back part of the tail, and the morning after be gently taken off: when it will be proper to plat the hairs, in order to keep them clean, and to ſet the tail, as will be directed in the plate and references.

Every two or three days, the tail ſhould be let down, and the upper part next the rump bathed with hot vinegar; and if it begins to crack, and the hair comes off, a little tincture of myrrh will ſoon put a ſtop to it. To obviate any threatening ſymptoms that may ariſe in regard to the wounds, have recourſe to the remedies uſed on docking.

After ſix or eight days, it will be proper to let the horſe ſtand without the machine for a few hours, and then be rode about, in order to obſerve how he carries his tail; by which means you will the better judge how to faſten it down, whether to confine it cloſer, or give it more ſcope: after the wounds are healed up, it may be neceſſary to keep the tail ſuſpended, till the callus is confirmed, at leaſt for ſome hours in the day; though a greater liberty may now be allowed it.

Thus this machine anſwers every intention, is far preferable to the pulley, as it keeps the tendons properly ſeparated, and the tail in a certain poſition; ſo that the wounds heal up uniformly, without any riſk of its being caſt to one ſide; the horſe alſo is more at eaſe, having no weight conſtantly pulling and teazing him, and may be taken out to water or exerciſe without any inconveniency, or diſturbance.

Directions for the Application of the Nicking Machine; and Explanation of the Plates.

When the hair of the tail is properly platted, and tied with a knot or two at the end, the pad, &c. as deſcribed in Plate XX. Fig. 9. muſt be put on, and the machine, as in Fig. 10. buck ed to them, letting the part G in the machine lie over the part of the tail that joins to the horſe's rump; then let an aſſiſtant, ſtanding on the ſide rail of the brake, or any other conveniency that may place him above the horſe, raiſe the horſe's tail very gently, till the knot of the tail gets ſo far beyond the ſtrings L L in Fig. 10. that it may be tied down; which being done, the tail may be let down lower, or taken up higher at pleaſure. It is to be obſerved, that the ligature is not made on the tail itſelf, but on the platted hair, at the extremity of the ſtump.

The machine, Fig. 10. muſt be made of a piece of tough wood, about a foot long, viz. from A to B, and about nineteen inches broad from C to D, and ſeven or eight inches thick. The under part muſt be hollowed, ſo as to let in the horſe's rump, and that the wings C D may reſt on his buttocks. To receive the tail, a groove muſt be cut from G to H, about three inches wide, and three deep at G, leſſening gradually both in height and breadth to H. Holes muſt be made at certain diſtances in the groove, as at H for the ſtring, and a nick cut to receive the billet from the ſtrap K. Two buckles fixed to the machine as at I I.

The pad, &c. are ſufficiently deſcribed in Fig. 9. and its references; the wood muſt be ſloped off from E to C and A, and ſo on the other ſide, to lighten the machine, and hollowed at B, G, and F.

Fig. 9. repreſents a horſe, with his tail in the frame or machine. A is a pad, to which is faſtened a circingle B. C C two ſide ſtraps, one on each ſide the horſe, faſtened to the circingle, to keep the machine from going to either ſide; D, a breaſt-plate, to prevent the pad, &c. ſlipping back. E, a ſtrap fixed to the pad, and buckling to the machine, to keep the tail on the ſtretch at pleaſure. F, the ſtring tied on the hair, to confine the tail down to the machine.

Fig. 10. from A to B is twelve inches; from C to D, meaſured with a ſtring drawn over E F, is nineteen inches. From the top of the groove at E to the bottom G, is three inches: From E to F, the wideſt part of the groove, is three inches, gradually narrowing, as a tail leſſens to its extremity. The dots about H are holes in the groove, through which a piece of tape or pack-thread muſt be put, according to the length of the dock, and the diſtance of the knot, to tie the tail down behind the knot. I I, the buckles to receive a ſtrap from the circingle on each ſide, as deſcribed in Fig. 9. which keeps the machine from turning to either ſide. K, the ſtrap with a billet and buckle, which comes along the back from the pad, and is faſtened to the machine, through a nick cut juſt above H. L L, the ſtrings to tie down the tail. B, G, F, the hollow to let in the rump.

Fig. 2. repreſents the horſe with the machine on, ſtanding directly before you, where the depth of it is ſhewn, being three inches.

C D, the extremities of the wings. E F, the upper part. *Bartlet's Farriery, page* 325.

NIGHT-FALL, the beginning of night.

NOPE, a bull finch, or red-tail, a ſmall ſinging bird, well known.

NUSHED, ſtarved in bringing up.

O.

OAK

OAK

OAK, a tree well known, and one of the principal materials in building ſhips, &c. being ſtrong in all poſitions.

All the ſorts of oaks are propagated from acorns, which ſhould be ſown as ſoon as poſſible after they are ripe; for if they are kept too long out of the ground, they ſeldom grow.

The manner of ſowing theſe acorns, if deſigned for a ſmall plantation, or to be removed, is, to prepare ſome beds of freſh earth, neither too ſtrong and heavy, nor too light and dry; in theſe beds you ſhould place the acorns in rows one foot aſunder, and about two inches diſtance in the rows, covering them about two inches thick with the ſame freſh earth; obſerving to leave none of them uncovered, to entice the vermin, which may, in a ſhort time, deſtroy all the ſeeds.

In the ſpring, when the plants begin to appear, you muſt carefully clear them from weeds; and if the ſeaſon proves dry, you ſhould refreſh them now and then with a little water, which will greatly promote their growth. In theſe beds the plants ſhould remain until the following autumn, obſerving conſtantly to keep them clear from weeds; at which time you ſhould prepare a ſpot of good freſh earth, in ſize proportionable to the quantity of plants, which ſhould be trenched and levelled: then towards the middle or latter end of October, you ſhould carefully take up the plants, ſo as not to injure their roots, and plant them out in rows three feet aſunder, and eighteen inches diſtance plant from plant; obſerving never to ſuffer the plants to abide long out of the ground, becauſe their roots would dry, and endanger the growth of the plants.

When they are planted, you ſhould lay a little mulch upon the ſurface of the ground, near their roots, to prevent the earth from drying too faſt; and if the ſeaſon ſhould prove very dry, you ſhould give them a little water to ſettle the earth to their roots.

When the plants have taken root in this nurſery, they will require little more care than to keep them clear from weeds, and dig the ground between the rows every ſpring; in doing of which, you ſhould cut off ſuch roots as extend very far from the trunk of the trees, which will render them better for tranſplanting again: you ſhould alſo prune off ſuch ſide-branches as extend themſelves very far, and would retard the upright ſhoot; but you ſhould by no means cut off all the ſmall lateral branches, ſome of which are abſolutely neceſſary to be left on, to detain the ſap for the augmentation of the trunk; for I have often obſerved, where trees have been thus cloſely pruned, that their heads have over-grown their bodies, ſo that they have bent downward and become crooked.

When theſe trees have remained in the nurſery three or four years, they will then be large enough to tranſplant to the places where they are to remain; for it is not proper to let them grow very large before they are planted out; becauſe theſe are very hazardous trees to remove when old, or after they have taken deep root.

The ſeaſon for this work is, as I ſaid before, in the autumn; at which time, if they are carefully taken up, there will be little danger of their ſucceeding. When they are planted, the ſurface of the ground ſhould be mulched about their roots, to prevent its drying too faſt; and if the ſeaſon is very dry, they ſhould be watered, to ſettle the earth to their roots, which may be repeated two or three times in very dry weather; but you muſt carefully avoid giving them too much water, which is very injurious to theſe trees, when newly removed.

You ſhould alſo ſtake them, to prevent their being ſhaken and diſturbed by the winds, which would retard their rooting. In tranſplanting of theſe trees, you ſhould by no means cut their heads, which is too much practiſed: all that ſhould be done, muſt be only to cut off any bruiſed or ill-placed branches, which ſhould be taken off cloſe to the place where they are produced: but there can be no greater injury done to theſe trees than to ſhorten their roots; for when the leading bud, which is abſolutely neceſſary to draw and attract the nouriſhment, is taken off, the branch often decays entirely, or, at leaſt, down to the next vigorous bud.

The trees, thus raiſed and managed, will, if planted in a proper ſoil, grow to a conſiderable magnitude, and are very proper for a wilderneſs in large gardens, or to plant in clumps in parks, &c. but if they are deſigned for timber, it is much the better method to ſow the acorns in the places where they are to remain; in order to which, you ſhould provide yourſelf in autumn with a ſufficient quantity of acorns, which ſhould be always taken from ſtraight, upright, vigorous-growing trees; theſe ſhould be gathered from under the trees as ſoon as may be after they are fallen, and, if poſſible, in a dry time, laying them thin in ſome open room to dry; after which they may be put in dry ſand, and preſerved in a dry place until the end of November, when you ſhould prepare the ground for planting them.

The directions here given are deſigned only for ſmall plantations in a garden or park, which are only for pleaſure: but where theſe trees are cultivated with a view to profit, the acorns ſhould be ſown where the trees are deſigned

ſigned to grow; for thoſe which are tranſplanted will never grow to the ſize of thoſe which ſtand where they are ſown, nor will they laſt near ſo long ſound: for in ſome places, where theſe trees have been tranſplanted with the greateſt care, and they have grown very faſt for ſeveral years after, yet they are now decaying, when thoſe which remain in the place where they came up from the acorns, are ſtill very thriving, and have not the leaſt ſign of decay: therefore, whoever deſigns to cultivate theſe trees for timber, ſhould never think of tranſplanting them, but ſow the acorns on the ſame ground where they are to grow; for the timber of all thoſe trees which are tranſplanted, is not near ſo valuable as that of the trees from acorns. I ſhall therefore add ſome plain directions for the ſowing of acorns, and managing of the young trees, during their minority, until they are out of danger, and require no farther care.

The firſt thing to be done is that of fencing the ground very well, to keep out cattle, hares, and rabbits; for if either of theſe can get into the ground, they will ſoon deſtroy all the young trees. Indeed, they will in a few years grow to be out of danger from the hares and rabbits; but it will be many years before they will be paſt injury from cattle, if they are permitted to get into the plantation; therefore, durable fences ſhould be put round the ground. If, in the beginning, a pale fence is made about the land, which may be cloſe at the bottom, and open above; and within the pale a quick-hedge planted, this will become a good fence by the time the pale decays, againſt all ſorts of cattle; and when the trees will have got above the reach of hares and rabits, ſo that they cannot injure them; for the bark of the trees will be too hard for them to gnaw.

After the ground is well fenced, it ſhould be prepared, by ploughing of it three or four times, and, after each ploughing, to harrow it well, to break the clods, and cleanſe the ground from couch, and the roots of all bad weeds. Indeed, if the ground is green ſward, it will be better to have one crop of beans, peaſe, or turnips, off the ground, before the acorns are ſown, provided theſe crops are well hoed to ſtir the ſurface, and deſtroy the weeds: for if this is obſerved, the crop will mend and improve the land for ſowing; but in this caſe the ground ſhould be ploughed as ſoon as poſſible, when the crop is taken off, to prepare it for acorns; which ſhould be ſown as ſoon as may be after the acorns are ripe: for although theſe may be preſerved in ſand for ſome time, yet they will be apt to ſprout; and, if ſo, the ſhoots are in danger of being broken and ſpoiled; therefore we would adviſe the ſowing early, which is certainly the beſt method.

In making choice of the acorns, all thoſe ſhould be preferred which are taken from the largeſt and moſt thriving trees; and thoſe of pollard trees ſhould always be rejected, though the latter are generally the moſt productive of acorns; but thoſe of the large trees commonly produce the ſtrongeſt and moſt thriving plants.

The ſeaſon for ſowing of the acorns being come, and the ground having been ploughed, and levelled ſmooth, the next work is to ſow the acorns; which muſt be done by drawing of drills acroſs the ground, at about four feet aſunder, and two inches deep; into which the acorns ſhould be ſcattered, at two inches diſtance. Theſe drills may be drawn either with a drill-plough, or by hand, with an hoe; but the former is the moſt expeditious method, therefore in large plantations ſhould be preferred. In the drawing of the drills, if the land has any ſlope to one ſide, theſe ſhould be made the ſame way as the ground ſlopes, that there may be no ſtoppage of the wet by the rows of plants croſſing the hanging of the land. This ſhould be particularly obſerved in all wet ground, or where the wet is ſubject to lie in the winter. When the acorns are ſown, the drills ſhould be carefully filled in, ſo as to cover the acorns ſecurely; for, if any of them are expoſed, they will entice the birds and mice; and if either of theſe once attack them, they will make great havock with them.

The reaſon of my directing the drills to be made at this diſtance, is for the more convenient ſtirring of the ground between the rows, to keep the young plants clean from weeds: for if this is not carefully done, it cannot be expected, that the young plants ſhould make much progreſs; and yet this is generally neglected by many who pretend to be great planters, who are often at a large expence to plant, but ſeldom regard them after: ſo that the young plants have the difficulty to encounter of the weeds, which frequently are four or five times the height of the plants, and not only ſhade and draw them, but alſo exhauſt all the goodneſs of the ground, and conſequently ſtarve the plants: therefore, whoever hopes to have ſucceſs in their plantations, ſhould determine to be at the expence of keeping them clean for eight or ten years after ſowing, by which time the plants will have obtained ſtrength enough to keep down the weeds: the neglecting of this has occaſioned ſo many young plantations to miſcarry, as are frequently met with in divers parts of England.

About the end of March, or beginning of April, the young plants will appear above ground; but before this, if the ground ſhould produce many young weeds, it will be good huſbandry to ſcuffle the ſurface over with Dutch hoes, in a dry time either the latter end of March, or the beginning of April, to deſtroy the weeds, whereby the ground will be kept clean, until all the plants are come up ſo far as to be plainly diſcerned; by which time it may be proper to hoe the ground over again; for by doing it early, while the weeds are ſmall, a man will perform more of this work in one day than he can in three or four, when the weeds are grown large: beſides, there will be great hazard of cutting off or injuring the young plants, when they are hid by the weeds; and ſmall weeds, being cut, are ſoon dried up by the ſun; but large weeds often take freſh root, and grow again, eſpecially if rain ſhould fall ſoon after, and then the weeds will grow the faſter for being ſtirred; therefore it is not only the beſt method, but alſo the cheapeſt huſbandry, to begin cleaning early in the ſpring, and to repeat it as often as the weeds are produced.

The firſt ſummer, while the plants are young, it will be the beſt way to perform theſe hoeings by hand; but afterwards it may be done with the hoe-plough; for as the rows are four feet aſunder, there will be room enough for this plough to work; and as this will ſtir and looſen the ground, it will be of great ſervice to the plants; but there will require a little hand labour where the plough is uſed, in order to deſtroy the weeds, which will come up in the rows between the plants; for theſe will be out of the reach of the plough, and, if they are not deſtroyed, they will ſoon over-grow and tear down the young plants.

After the plants have grown two years, it will be proper to draw out ſome of them, where they grow too cloſe; but in the doing of this, great care ſhould be had not to

injure the roots of thoſe left; for as the plants which are drawn out are only fit for plantations deſigned for pleaſure, ſo theſe ſhould not be ſo much regarded in their being removed, as to ſacrifice any of thoſe which are deſigned to remain. In the thinning of theſe plantations, the plants may, at the firſt time, be left about one foot aſunder, which will give them room enough to grow two or three years longer; by which time it may be eaſy to judge which are likely to make the beſt trees. Therefore theſe may be then fixed on, as ſtandards, to remain; though it will be proper to have a greater number at this time marked than can be permitted to grow, becauſe ſome of them may not anſwer the expectation: and, as it will be improper to thin theſe trees too much at one time, ſo the leaving double the number intended at the ſecond thinning will not be amiſs. Therefore, if they are then left at about four feet diſtance in the rows, they will have room enough to grow three or four years longer; by which time, if the plants have made good progreſs, their roots will have ſpread over the ground; therefore it will be proper to take up every other tree in the rows. But, by this, I do not mean to be exact in the removing, but to make choice of the beſt plants to ſtand, which ever rows they may be in, or if they ſhould not be exactly at the diſtance here aſſigned: all that is deſigned here, is, to lay down general rules, which ſhould be as nearly complied with as the plants will permit: therefore every perſon ſhould be guided by the growth of the trees in the performance of this work.

When the plants have been reduced to the diſtance of about eight feet they will not require any more thinning. But in two or three years time, thoſe which are not to remain will be fit to cut down, to make ſtools for underwood; and thoſe which are to remain, will have made ſuch progreſs as to become a ſhelter to each other; for this is what ſhould principally be attended to, whenever the trees are thinned; therefore, in all ſuch places which are much expoſed to the wind, the trees ſhould be thinned with great caution, and by ſlow degrees, for if the air is let too much at once into the plantation, it will give a ſudden check to the trees, and greatly retard their growth, but, in ſheltered ſituations, there need not be ſo great caution uſed as in thoſe places; the plants will not be in ſo much danger of ſuffering.

The diſtance which I ſhould chuſe to allow to thoſe trees which are deſigned to remain for timber, is, from twenty-five to above thirty feet, which will not be too near, where the trees thrive well; in which caſe their heads will ſpread, ſo as to meet in about thirty, or thirty-five years: nor will this diſtance be too great, ſo as to impede the upright growth of the trees. This diſtance is intended that the trees ſhould enjoy the whole benefit of the ſoil. Therefore, after one crop of the underwood, or, at the moſt, two crops are cut, I would adviſe the ſtubbing up the ſtools, that the ground may be intirely clear, for the advantage of the growing timber, which is what ſhould be principally regarded: but, in general, moſt people have more regard for the immediate profit of the underwood than the future good of the timber, and, frequently, by ſo doing, ſpoil both: for, if the underwood is left after the trees have ſpread ſo far as that their heads meet, the underwood will not be of much worth; and yet by their ſtools being left, they will draw away a great ſhare of nouriſhment from the timber-trees, and retard them in their progreſs.

The ſoil in which oak makes the greateſt progreſs, is a deep rich loam, in which the trees grow to the largeſt ſize; and the timber of thoſe trees which grow upon this land, is generally more pliable than that which grows on a ſhallower or drier ground; but the wood of the latter is much more compact and hard. Indeed there are few ſoils in England in which the oak will not grow, provided there is proper care taken in their cultivation; though this tree will not thrive equally in all ſoils: but yet it might be cultivated to a national advantage upon many large waſtes in many parts of England, as alſo to the great profit of the eſtates where theſe tracts of land now lie uncultivated, and produce nothing to the owner. And, ſhould the preſent temper of deſtroying the timber of England continue in practice ſome years longer, in the ſame degree which it has for ſome years paſt, and as little care be taken to raiſe a ſupply, this country, which has been ſo long eſteemed for its naval ſtrength, may be obliged to ſeek for timber abroad, or be content with ſuch a naval ſtrength as the poor remains of ſome frugal eſtates may have left growing: for, as to the large foreſts, from whence the navy has been ſo long ſupplied, a few years will put an end to the timber there: and how can it be otherwiſe, when the perſons to whoſe care theſe are committed, reap an advantage from the deſtruction of the timber? *Miller's Gard. Dict.*

OAK-BARK. *See the article* BARK *and* TAN.

OATS, the name of a well known ſpecies of grain, and of which Mr. Miller reckons four ſorts, cultivated in England, viz. the white, the black, the brown or red, and the naked oat, in which, though ſuppoſed to be only accidental varieties, he has never obſerved any alteration where they have been cultivated ſeparately for many years. Their principal difference is in the colour of their grain.

The white ſort, which is moſt common about London, makes the whiteſt meal, and is chiefly cultivated where the inhabitants live much upon oat-cakes. The black oat is more cultivated in the northern parts of England, and is eſteemed a very hearty food for horſes. Red oats are much cultivated in Derbyſhire, Staffordſhire, and Cheſhire, but are ſeldom ſeen in any of the counties near London; though, as they are a very hardy ſort, and yield a good increaſe, they will be well worth propagating, eſpecially in all ſtrong lands. The ſtraw of theſe oats is of a browniſh red colour, as is alſo the grain, which is very full and heavy, and eſteemed better food for horſes than either of the other ſorts. The naked oat is leaſt common in the ſouthern parts of England; but in the northern counties, in Scotland, and in Wales, it is pretty much cultivated, and is particularly eſteemed, becauſe its grain threſhes clean out of the huſk, and need not be carried to the mill, to be made into oat-meal or griſt.

As oats are very hardy, and will thrive in almoſt any ſoil, they have been a great improvement to many eſtates in the northern parts of this kingdom, where, though ſown even ſo late as April, and in ſtiff ground, they have ripened early, and yielded a good crop. However, February, or March, according as the ſeaſon proves early or late, is a more common and better time for ſowing this corn, of which it will always be right to ſow the largeſt grain ſort earlieſt.

Oats are often ſown after a crop of wheat, rye, or barley; in which practice the common method is to turn in the ſtubble, with one ploughing, about the beginning of Feb-

February, and ſow the ſeed with a broad-caſt at twice, harrowing it in, once after the firſt ſowing, and five or ſix times after the ſecond, obſerving to draw the harrow once or twice acroſs the furrows, to break the clods and cover the ſeeds; but at the other times to harrow in the ſame direction as the furrows, leſt the ſtubble ſhould be raiſed on the ſurface. But it would be much better huſbandry to plough in the ſtubble in autumn, that it may rot in winter, and to give the land another ploughing, and a good harrowing, juſt before the oats are ſown. This will render the ground finer, and fitter to receive the grain, the increaſed produce of which will amply repay the extraordinary expence of tillage. M. Duhamel, after obſerving that every farmer knows, though but few practice it, that all crops of ſpring-corn are greatly bettered by this method, inſtances the example of M. d'Elu, one of his correſpondents, who having given three ploughings to ſome of his oat-lands, had, in 1759, a year remarkably dry, and unfavourable to ſpring-corn, a plentiful crop of oats, which held up well till they were perfectly ripe, and yielded excellent grain.

Another thing, which I muſt alſo inſiſt on, is, that if farmers were to follow the directions before given, in regard to the changing of crops, by which means oats, which impoveriſh the ground, would always ſucceed ſome one of the meliorating crops, the return would be much more plentiful than in the common way, becauſe the earth would be in a much looſer ſtate.

When oats, as it frequently happens, are ſown upon a lay, or on ground newly broken up, after only one ploughing, which is given in January, when the earth is moiſt, to turn down the ſward; the harrowing muſt be in the ſame direction as the furrows, or but very little acroſs, for fear of raiſing the turf. But this again is bad huſbandry: for the ground would be brought to a much better tilth for other grain, as a preparation for which this ſowing is chiefly intended, by giving the ſward time to rot before the oats are ſown; becauſe the roots of the graſs will prevent thoſe of the corn from ſtriking downward.

Black oats delight in a moiſter ſoil than the white ſort, and, being a hardier plant, may be ſown a month earlier. The white, which prefer a dry land, and will do well on gravel and ſand, are the beſt of all corn for ground ſubject to quick-graſs or weeds, becauſe it may be ploughed later for them, and they riſe ſooner, and top the weeds better than black oats. The weather cannot be too dry when white oats are ſown; though the ground may then be moiſter for them than barley will endure; becauſe this laſt, having a thinner coat, is ſooner chilled by imbibing the wet, which may perhaps burſt many of its veſſels; whereas white oats, being protected by a double huſk, better reſiſt the entering of the moiſture. Mr. Liſle, who makes theſe remarks, adds, that, according to the beſt of his obſervations, white-oats require a rich feeding ſoil; becauſe their haulm, or ſtraw, running to a great largeneſs, cannot be ſupported without good juices and moiſture; that white chalky ground, though in never ſo good heart, will be unfruitful with white oats; and that a mixed mould, between white earth and red clay, of which there is a great deal in the hilly parts of Hampſhire, is not feeding enough for them. The red and the white clays, when in good heart, carry moiſture enough, and are very fit for this grain.

The common allowance of ſeed oats is four buſhels to an acre; but Mr. Miller rightly thinks three buſhels more than enough: and the uſual produce is about twenty-five buſhels from an acre; though he obſerves, that he has ſometimes known more than thirty buſhels reaped from that extent of ground; and we can ſay with truth, from an accurate account now in our poſſeſſion, that a gentleman, who is indeed an excellent huſbandman, has had, for a continuance, forty-eight buſhels of oats from off each acre of his land ſown with that grain. I do not mean forty-eight buſhels of naked oats; for the produce of that ſort is the leaſt of any in bulk, becauſe its grains are ſmall, and lie very cloſe together: but they make up in value, for what is wanting in meaſure. White oats always produce a greater increaſe than black oats. Mr. Liſle threſhed a ſtack of twenty-eight loads of the former, and found it yield more grain than a ſtack of thirty-eight loads of the latter; and farmers in general account an ordinary crop of white oats as good as a middling crop of black oats. This laſt ſort is alſo moſt liable to blight, eſpecially if a hot ſummer follow a dry cold ſpring, and the grain has been ſown on lay ground. Their culture is alike; and the manner of mowing and ordering them at harveſt exactly the ſame. Only it is to be obſerved, that white oats are apt to ſhed moſt as they lie, and black oats as they ſtand.

In the year 1709, Mr. Liſle ſowed, in the beginning of May, in ſome of his wheaten ground, where the corn had been killed by the preceding hard winter, rath-ripe barley in one part, and ſhort grained white oats, which he diſtinguiſhes by the name of white Poland oats in another. Both grains were ſown on the ſame day, in an equally fertile, moiſt and well tilled ground. He made no doubt but that the Poland oat would be firſt ripe, and was therefore ſurpriſed to ſee the rath-ripe barley ſpring up ſooneſt, by four or five days: but reflecting on the nature of each grain, he ſoon concluded the reaſon to be, that the oat, having a double hull, and being conſequently better guarded from moiſture, could not imbibe the vegetable water ſo ſoon as the barley; but that, the texture of the flour of the oat, and the infolded fibres of the incloſed plant being ſofter, it would conſequently grow faſter. From hence he infers, that, to ſecure the growing of Poland oats without rain, they muſt be committed to the earth before it becomes ſo dry as is proper for the ſowing of barley, not only becauſe the oats require more moiſture to make them grow, but alſo becauſe they lie ſo many days longer in the ground, before they come up, than the barley does.

When oats are about four inches high, intelligent huſbandmen run a wooden roller over them, after a ſhower of rain has ſoftened the clods, by the breaking of which in this manner, freſh earth is laid to the roots of the plants, their tillering is conſiderably increaſed, if they have not been ſown too thick, and the ſurface of the field is ſmoothed; ſo that the mowers, at harveſt, are able to cut cloſe to the ground, as it is very fit they ſhould, becauſe oats ſeldom grow high. Both oats and barley ſhould be carefully weeded.

Oats are ripe when the ſtraw turns yellow, the grain becomes hard, and the chaff begins to open and ſhew the ſeed. When mowed, they are generally let lie ſome time for the dew and rain to plump them, and make them threſh well, and, if weedy, to kill the weeds: but if rain wet them much, they ſhould be carried off as ſoon as they can be got tolerably dry again, or they will ſhed; for oats may be inned the wetteſt of any corn, if the

weeds

weeds among them be but dead. Even in very rainy harveſts when other grain is ſpoiled, this will receive little or no damage, the ſurface of its ſtraw and ears being ſo ſmooth and compact as to turn off water, and of ſo dry a nature, that, though houſed wet, they will not heat in the mow, or become mouldy, as other grains uſually do. This is a vaſt advantage in northern climates, where the harveſt is generally late, and the autumn wet.

M. Duhamel is ſtrongly of opinion, that farmers, eſpecially thoſe who keep many cattle, would find their account in houſing their oats directly, without letting them lie out after they are cut, as is the common way, that rain and dews may moiſten, and conſequently ſwell their grain. He earneſtly adviſes huſbandmen to try the experiment upon a part of their crop; "becauſe," ſays he, "the fodder will, by this means, certainly be much better for cattle, and much leſs grain will be loſt in the field. It may be objected, that theſe oats will be difficult to threſh; to which I anſwer, that if this be the only inconvenience, the ſuperior quality of the fodder, and the ſaving of a quantity of grain, which would otherwiſe be ſhed, will probably more than pay the extraordinary wages of the threſher.

"But allowing that the oats thus houſed cannot be threſhed quite clean, and that ſome grain will neceſſarily remain in the ears, I ſay, that this will not be loſt to the farmer; for he is obliged to give his cattle unthreſhed oats, and they will eaſily find the grains remaining in the ſtraw, which will not perhaps exceed the quantity that would have been dropped in the field: and even granting, though it will not happen, that the greateſt part of the grain be left in the ear, ſtill it will not be loſt in the hands of an intelligent farmer; for what ſhould hinder him from giving it to his horſes? ſuppoſing that four ſheaves yield a buſhel of oats, he need only give his horſes thoſe ſheaves inſtead of a buſhel of corn. They will certainly be longer in feeding upon four ſheaves, than upon a buſhel of cleared oats; and at the ſame time they will eat ſome ſtraw with the corn, which will ſupply the place of other fodder, and probably prove a more healthy food." This method may be particularly beneficial to ſuch as live in very hot countries, or in very dry ſeaſons.

Mr. Liſle, refuting the opinion of thoſe who think that oats cut green will ripen while they lie in ſwarth, ſays, "If, by ripening be meant ſhrinking, drying, or withering, I muſt allow the poſition; but if the countryman will have it, that the greeniſh oat, cut a fortnight or ten days, or be it but a week, before it is ripe, will proceed in its vegetable increaſe, and ſwell as well as harden by lying in ſwarth, I muſt deny it. This year (1707) I made a full experiment of this matter; for when the ſpring corn was ſown, the ground being generally dry, half the oats and barley came not up till the latter end of May, when rain came, whereby in moſt places half the crop was edge-grown. The forward oats being then in danger of ſhedding, we were forced to cut down the greeniſh corn with the ripe, when otherwiſe we ſhould have waited ten days longer. I let them lie in ſwarth above a week, and, when I carted them, I found the hull of the greeniſh oat had got a riper colour, and the pith was well hardened, but pitifully lean and ſhrunk; ſo that though this is to be done on neceſſity, yet it ought not to be practiſed with ſuch indifference as is uſual among farmers. Note, the pith of theſe green oats was well paſt the milk, and came to a floury ſubſtance."

The ſame gentleman adds, that oats are the worſt of all grain to keep, becauſe of the great moiſture in them, and their conſequent aptneſs to heat when laid in a heap; and that when the heat has been ſuch as to ſpoil them for growing, their hulls look as red as a fox.

The meal of oats makes tolerably good bread, and is the common food of the country people in the North. In ſome places beer is made with this grain: in Ruſſia in particular the poorer ſort make with it a drink, which they call *quas*; but its principal uſe is for the food of horſes, for which purpoſe it is reckoned very wholſome, being ſweet, and of an opening nature: but it muſt not be given them before it has ſweated in the mow, or been otherwiſe dried, leſt it ſhould prove too laxative.

The very long drought of the ſummer 1762, ſhewed another very profitable uſe of oats on ſuch occaſions; and probably it will anſwer equally well in the winter. Some milk-men near London boiled oat meal in the water which they gave their cows to drink, and found that the expence was abundantly repaid, by the additional quantity of milk which theſe cows yielded more than thoſe which had not this maſh.

The following Letter from Mr. Lamb, *on the beſt Method of cultivating Black Oats, and recommending more frequent Ploughings than any uſually afforded them, will, we are perſuaded, be acceptable to our Readers.*

Gentlemen,

"Having been for many years a practical farmer in the eaſtern part of the county of Eſſex, you will not, I hope, think me impertinent in troubling you on the culture of black oats, which I have very often to great advantage ſown.

"Moſt of my neighbours prefer the white Poland oat, which may, I own, in ſome circumſtances of ſoil and ſituation, be beſt. I prefer the black oats becauſe they are hardieſt, for which reaſon they ſuit beſt with my convenience; for, as a conſiderable tract of the farm I occupy is light land, I am under a ſort of neceſſity of ſowing this ſoil early, or, if a dry ſummer followed, I ſhould have no return at harveſt.

"Few people allow more than one ploughing for a crop of oats; but ſuch as follow this practice are very wrong-headed; for they may aſſure themſelves, that no crop pays better for ploughing than oats; and it is on this account that I generally give my land deſigned for oats three tilths; whence I am morally certain ariſes the largeneſs of my crops, for I have ſeldom under five, oftener ſix, and very frequently ſeven quarters from an acre, throughout a field.

"Your readers will not be ſurpriſed at my having ſuch good crops, when I obſerve, that I almoſt every year ſow ſome oats on a fallow that has been well dunged; and this I aver to be good huſbandry, as it abates the rankneſs of the ſoil, kills many of the weeds, and prepares the land in an excellent manner for a ſucceeding crop of ſweet wheat; buſt I muſt obſerve, that I always clear my land of the ſtiff oat-ſtubble before I attempt to plough for the wheat.

"I have already ſaid that I ſow black oats early on my light land: by early, I mean as early as the firſt week of February, by which time I have generally an opportunity of getting the land in proper order, for a light ſoil is ſoon wet, ſoon dry.

"Let me mention once more to your readers, that it is on a light ſoil, which is apt to burn a crop, that I ſow my black

black oats ſo early as the beginning of February; for ſhould any of them attempt to ſow them ſo early in a moiſt, cold, ſtiff ſoil, and a hard froſt ſhould follow, the young blade would, in all probability, be killed.

"I muſt alſo remark, that when I ſow oats thus early, it is generally under furrow; yet I ſometimes ſow them broad caſt, and plough them in.

"The quantity of ſeed I, for the moſt part, uſe, is about three buſhels, which I find to be enough; nay, I have ſometimes from only two buſhels had a good crop; but then I have been particularly careful and attentive to the goodneſs of the ſeed, without which precaution I ſhould not, unleſs the ſeaſon had been very favourable indeed, have ſucceeded.

"I have found it a very good way to ſow firſt half my quantity of ſeed under furrow, and afterwards, ſowing the remainder broad-caſt, harrow it in; and this is often my practice when I ſow the latter end of February, or the beginning of March.

"When I ſow oats after wheat, which however is not very frequently, I turn up the ſtubble as ſoon as I conveniently can after harveſt, and leave it rough through the winter. The firſt fine weather after Chriſtmas, I lay it down ſmooth with the harrows, and immediately give it a croſs ploughing.

"As ſoon as February comes in, if it is not a hard froſt, I make the land as fine as I poſſibly can by the harrows, raiſing a fine looſe mould to the ſurface, which is to be the bed for the oats to lie in; for I ſow my oats directly under furrow; after which I paſs a moderate-ſized roller over the field, and then give it a ſlight ſcratch with a pair of light harrows.

"This huſbandry generally produces me a crop I have no reaſon to complain of.

"My chief reaſon for troubling you with this letter is, to endeavour to perſuade my brother farmers that they do not, in general, allow their oats a ſufficient number of ploughings, one being the ſtated quantity.

"If they would plough twice for this crop, they would receive more than twenty ſhillings an acre for their trouble; but if they would conſult their own intereſts, and allow three ploughings, it would often make fifty pounds difference to them in a field of twenty acres: this they will, perhaps, think wonderful; but it is no leſs true.

"The black oats require particularly to be ſown early, eſpecially if the farmer wiſhes to have them of a fine gloſſy ebon colour, and that the crop ſhould corn well; for if they are ſown late, and wet weather follows ſoon after ſowing, they will be apt to run all to ſtraw; and if dry weather, and the ſoil is gravelly, it is a chance but they are burnt up.

"I have found by experience, that black oats will yield a very large crop after turnips; and this I believe is ſimply owing to their being ſown in a fine tilth; for the mould cannot but be reduced to very ſmall particles if a crop of turnips has been well huſbanded, eſpecially if it is in a light ſoil.

I am, &c.

East of Chelmsford, Eſſex. J. LAMBE."

Wild OATS, a ſpecies of oats difficult to be extirpated where they have once taken poſſeſſion; for ripening before harveſt, and ſcattering their ſeed round them, they will remain in the ground till it is ploughed up again, though it be for a whole year, ſome ſay four or five years, and will then come up with the corn. The ſureſt way to deſtroy them, is to lay the ground down to clover, and to mow the oats and clover together before the oats are ripe.

OILS, the beards, or prickles of barley, &c.

OLLET, fuel of any kind.

OMY, mellow; ſpoken of land.

OPE-LAND, ground that is looſe or open, from its being ploughed up every year.

ORCHARD-GRASS, the name of a ſmall, coarſe, but very ſweet graſs. It is of very quick growth, and may poſſibly hereafter be cultivated to advantage.

ORE-WEED, a general name for weeds growing at the bottom of the ſea, and alſo on the muddy and rocky parts of the ſhore.

Sea-weeds are ſo beneficial a manure, that farmers ought not to grudge the expence of carrying them a few miles. In Devonſhire, Cornwall, and other maritime parts of England, theſe weeds are laid in heaps till they are rotten, and then ſpread upon the land, about a load to three rods: but this laſts only one year, unleſs ſand, or a ſtiff earth, according to the quality of the ſoil intended to be improved, be laid on or mixed with them; and then they become a laſting manure. In ſome places, theſe weeds are gathered in heaps, and burnt as ſoon as they are dry; after which about a buſhel of their aſhes is laid on upon three rods of ground. But theſe, like all other aſhes, ſhould be mixed with ſand, or ſtiff earth, if you would have the land laſt good: otherwiſe, they are only an improvement for a year. Theſe aſhes are particularly good for graſs grounds over-run with moſs. Looſe ſandy ſoils are likewiſe peculiarly benefited by this weed: but, being a ſub-marine plant, the wind and ſun ſoon exhale its moiſture; ſo that the more ſpeedily it is taken from the ſhore, where ſtorms often throw it up in great quantities, the better it is. When ſpread on the ground, and afterwards covered over, it ſoon diſſolves into a ſalt oily ſlime, proper to fertilize and bind light ſoils. This is the moſt approved way of applying it: though ſome lay it naked and freſh from the ſea, upon their barley lands, towards the end of March and beginning of April, and have a good crop of corn: but ſuch quantities of rank weeds are apt to ſhoot up afterwards, that no wholeſome plant is to be expected that year.

The value of the lands all along the coaſt of Scotland has been more than doubled by the uſe of this excellent manure. It is chiefly uſed there for barley; and the farmers watch every opportunity when it is thrown in by the ſea, and lay it on at all ſeaſons, in autumn, winter, and ſpring. But if they could chooſe their time, it would probably do beſt about the month of March; for being then ploughed into the ground, and afterwards ploughed up again to the ſeed, it would be incorporated and blended with the ſoil; whereas, if it be laid on in autumn, before the fallowing or firſt ploughing, it is too much waſted before the ſpring; and if it be laid on to the ſeed-furrow, it is apt to burn the ground in a dry ſeaſon, though it will do very well in this method in a wet ſummer. Its effects are but juſt felt the ſecond year; though it is laid on thicker upon ſtrong clay land, which receives no other manure for three crops, viz. barley, oats, peaſe, and beans; a method which might, perhaps, be altered for the better by omitting the oats, and ſowing alternately barley, and peaſe and beans, and laying on the ſea-ware,

as

as theſe weeds are commonly called, for every ſecond crop of peaſe and beans.

We ſee by the abridgement of Mr. Scott's account of the manner of uſing ſea-ware in Scotland (publiſhed by Mr. Maxwell in his Miſcellaneous Papers) that much of this valuable manure muſt neceſſarily be loſt through want of proper management: for they have no reſervoirs to keep it in, when thrown aſhore at a ſeaſon in which they cannot uſe it, or where there is no ground in tilth, as is generally the caſe in winter, and during the buſy part of their hay and corn harveſt. It ſhould be collected on theſe occaſions, and lodged in a place free from any running water; and, as it is equally beneficial to ſtrong or light lands, it might be there covered with ſand or clay, according to the nature of the ſoil for which it is intended. This will prevent its being parched by the ſun, or its diſſolving into a putrid maſs, which, if not ſecured in this manner, would either be waſhed away by rains, or fly off into the air: whereas, when thus covered, it would greatly enrich the clay or ſand, and render them good manures for their oppoſite ſoils. If it be thrown aſhore at a time when it can be ploughed in directly, that is certainly the beſt manner of uſing it.

Mr. Scott obſerves, that there is a kind of land all along the coaſt, which is gravelly, and covered over ſo thick with ſea-ſtones, that, to look at it, one would not think corn could ſpring through them; and another ſort of land, which is a deadiſh ſand. To both theſe grounds ſea-ware is the only manure; for dung of all kinds has been often tried, but with no ſucceſs; and yet ſea-ware makes them bring excellent crops of barley. This kind of ground is ſeldom ploughed more than twice, and the ſea-weed is generally laid on before the firſt ploughing. Barley is ſowed during two years, and peaſe the third; a freſh manure of ſea-weed being laid on each year that barley is ſown. As little wheat is cultivated in the country where Mr. Scott lived, the farmers there might probably improve their practice of raiſing barley and peaſe, by ſowing them alternately, and laying the ſea-ware to the peaſe. In the ſummer, it is carried to a diſtance from the ſea, and laid upon ley-ground (arable land under graſs) which, though in very ill heart, will bear a good crop of oats with only once ploughing, or of barley, if ploughed again in the ſpring.

Another kind of ſea-ware, of a much ſtronger nature than that which is thrown up by the waves, is cut from the rocks at low water, and will laſt three years. It coſts more labour, but brings greater recompence. Mr. Scott thinks the beſt time of laying this on the ground would be in autumn, before the land is ploughed rough for a ſpring crop.

The farmers on the coaſt of Scotland (and I believe the ſame may be ſaid, in general, of thoſe in moſt of the maritime parts of England) prefer this manure to any other, eſpecially for their light grounds; and it has the advantage of being much more eaſily tranſported, becauſe one load of it will go as far as two of dung.

It does very well in kitchen-gardens, where Mr. Scott ſays he has ſeen pot-herbs and roots of an extraordinary ſize produced by its help; to which he adds, that he has known fruit-trees, perfectly barren before, rendered extremely fruitful by laying this manure about the roots.

Mr. Duhamel likewiſe informs us that theſe ſea-weeds are uſed with great ſucceſs in the maritime provinces of France.

OST, *Ooſt*, or *Ouſt*. *See* OUST.

OVER-REACH, a wound in the fore-heel of a horſe, made by the point of the hind-ſhoe.

When this wound is only ſlight or ſuperficial, it is, in general, very eaſily cured by waſhing it clean, and applying the wound ointment: but it ſhould be obſerved from the nature and manner of the injury, where the blow has been ſmart, that it differs widely from a common cut; the part here being both torn and bruiſed, and conſequently it requires to be properly digeſted, in order to lay a good foundation for healing.

For this purpoſe, after waſhing out any dirt or gravel with ſope-ſuds, &c. let the wound be digeſted, by dreſſing it with doſſils of lint dipped in an ounce of Venice turpentine, divided with the yolk of an egg, to which half an ounce of tincture of myrrh may be added; over this dreſſing it would be adviſable to apply the turnip poultice, or that with ſtrong beer grounds and oatmeal, three or four times, or oftener, till the digeſtion is procured, and then both theſe dreſſings may be changed for the precipitate medicines, or the lime-water mixture; obſerving always to apply the doſſils carefully to the bottom, to fill up the ſore with the ſame even to the ſurface, and to bind all on with a compreſs and roller: and if any cavities appear that cannot conveniently be dreſſed to the bottom, they ſhould always be laid open, or no proper foundation for healing can be obtained. The hoof alſo ſhould be kept ſupple, or pared away, when the growth of it interrupts this end, as is ſometimes the caſe. *Bartlet's Farriery, page* 244.

OUGHTS, leavings.

OUST, a kiln, generally applied to that uſed in drying hops.

It is built with fire-places in the nature of malt-kilns; and at a proper diſtance over the fire is an hair-cloth ſtrained upon laths; and thereon the hops are laid, and raked even to the depth of about ſix or ſeven inches, for the better conveniency of drying them equally; and when they are properly cured on the under ſide, they are carefully turned; and by that means the upper ſide becoming the under, the whole ſhares the fire alike. The perſon that performs this part is called the dryer, whoſe buſineſs it is to manage the fires.

The fuel commonly made uſe of is charcoal, for its freeneſs from ſmoke, and affording a ſteady heat. Great nicety is required in this part; a ſmall fire being to be made, at firſt, that they may heat gradually, and ſo raiſed as they dry, that it may be done without ſcorching; and the fire is to be lowered by degrees, againſt they are ready to be taken off: the time required is about eight hours.

But as charcoal is very dear, being three or four pounds per load, many people have adopted the method of drying with ſea-coal, upon what they call cockle-ouſts, which are ſquare iron-boxes placed upon brick-work, and a flue and chimney in the back part of the building for the ſmoke to go off. The computation is, that a chaldron of ſea-coal, at about twenty-four ſhillings, will dry a load of hops; and that a load of charcoal will do no more. It is indeed expenſive to erect ſuch ouſts, as there muſt be no timber near them; and an iron-beam and iron-laths are to be uſed, and they covered with plates of tin or iron properly faſtened together.

A gentleman has lately claimed the merit of having invented a new method of drying hops with ſea-coal, or any kind of fuel whatever, by means of a moveable iron furnace: it is in form of an horizontal cylinder, ſtopped at both ends:

ends: it lies on an iron carriage, which rolls on four iron-wheels: in the fore-end of the cylinder is the furnace door, and a hollow iron flue runs in an horizontal direction along the upper ſurface of the cylinder from the back till it reaches the fore-end of it, when it takes a vertical direction, and is carried as high as is neceſſary to convey the ſmoke out of the ouſt. We cannot pretend to ſay what are the particular advantages reſulting from the uſe of this rolling furnace, never having ſeen it at work.

OUST-HOUSES, out-houſes, or ſuch as belong to, and are adjoining to the dwelling-houſes.

OX, the name of an animal well known, being a bull caſtrated.

Oxen, like other domeſtic animals, vary in colour, though the dun ſeems the moſt common; and the redder it is, the more it is eſteemed. A black coat is alſo valued; and bay oxen are ſaid to be vigorous and long lived; whereas the brown ſoon decay. The grey, the dappled, and the white, are proper only for the ſlaughter; no care can render them fit for labour; but whatever be the colour of an ox's coat, it ſhould be gloſſy, thick, and ſmooth to the touch; for if it be harſh, tough, or thin, there is reaſon to ſuppoſe that the animal is out of order, or at leaſt not of a ſtrong conſtitution. A good ox for the plough muſt be neither too fat nor too lean; the head ſhort and thick; the ears large and ſhaggy; the horns ſtrong, gloſſy, and of a middling ſize; the forehead wide, the eyes full and black; his muzzle large and flat; the noſtrils wide and open; the teeth white and even; the lips black; a fleſhy neck, large and heavy ſhoulders; the breaſt broad; the dew-lap hanging down to the knees; the reins very broad; a ſpacious deſcending belly; the flanks firm; the haunches large; and the rump thick; large and nervous thighs and legs; the back ſtraight and full; the tail reaching to the ground, and well covered with thick and fine hair; the feet firm; the hide thick and pliable; the muſcles raiſed; the hoof ſhort and broad: he muſt alſo anſwer to the goad, be obedient to the voice, and well trained; but it is only gradually, and by beginning early, that the ox can be brought willingly to bear the yoke, and be eaſily governed. At the age of two years and a half, or three at the lateſt, you muſt begin to tame him, and bring him under ſubjection; if delayed longer, he becomes froward, and often ungovernable. The only method of ſucceeding is, by patience, mildneſs, and even careſſes, for compulſion and ill-treatment will only diſguſt him irreclaimably; ſtroaking him gently along the back, clapping him, giving him occaſionally boiled barley, ground beans, and ſuch other aliments as pleaſe him beſt, all of them mingled with ſalt, of which he is very fond, will prove of the greateſt uſe. At the ſame time his horns ſhould be often tied, and ſome days after the yoke is to be put on his neck, and faſtened to a plough, with another ox of the ſame ſize ready trained; theſe are to be tied together at the manger, and in the ſame manner led to the paſture, that they may become acquainted, and accuſtomed to have one common motion. The goad is never to be made uſe of in the beginning, as that would only render him more untractable; he muſt alſo be indulged, and labour only at ſhort intervals; for till he is thoroughly trained, he tires himſelf very much; and for the ſame reaſon he is to be fed more plentifully than at other times.

An ox is to draw the plough only from his third to his tenth year, when it will be adviſable to fatten and ſell him, as being then of a better fleſh than if he was kept longer. The age of this creature is known by his teeth and horns. The firſt fore-teeth, which he ſheds at the end of ten months, are replaced by others, larger, but not ſo white; at ſix months the teeth next to thoſe in the middle fall out, and are alſo replaced by others; and in three years all the inciſive teeth are renewed. They are then equal, long, and pretty white; but as the ox advances in years, they wear, become unequal, and black. It is the ſame in the bull and cow: ſo that the growth and ſhedding of the teeth are not affected by caſtration, or the difference of ſexes. Nor is the ſhedding of the horns affected by either; as both bull, ox, and cow, loſe them alike at the end of three years; and theſe alſo are replaced by other horns, which, like the ſecond teeth, remain; only thoſe of the ox and cow are larger and longer than thoſe of the bull. The manner of the growth of theſe ſecond horns is not uniform, nor the ſhooting of them equal. The firſt year, that is the fourth year of the ox's age, two ſmall pointed horns make their appearance, nearly formed, ſmooth, and towards the head terminated by a kind of button. The following year this button moves from the head, being impelled by a corneous cylinder, which alſo lengthening, is terminated by another button, and ſo on; for the horns continue growing as long as the creature lives. Theſe buttons become annular joints, which are eaſily diſtinguiſhed in the horn, and by which the age of the creature may be readily known; counting three years for the point of the horn to the firſt joint, and one year for each of the other intervals.

OX-BOOSE, an ox-ſtall, or cow-ſtall, where theſe creatures ſtand in the winter.

OX-HARROWS, very large harrows, called in ſome counties, drags.

OX-GANG, or *Ox-gate*, a quantity of land meaſuring fifteen acres, being as much ground as a ſingle ox is ſuppoſed to be capable of ploughing in a year.

P.

PAL PAN

PACK-SADDLE, a ſaddle adapted to the carriage of heavy packs or burdens.

PAD, the road, a foot-path; alſo an eaſy paced horſe: likewiſe a low ſaddle.

PADDLE-STAFF, an inſtrument uſed by the ploughman to free the ſhare from ſtubble, clay, &c. which hinder its action.

PADDOCK, a ſmall field or incloſure. It alſo ſignifies a large frog or toad.

PAIGLE, a cowſlip.

PAIL, a wooden veſſel in which milk or water is commonly carried.

PALMS, the male flowers of the willow.

PALSY, a diſeaſe common to horſes, wherein the body or ſome of its members, loſe their motion, and ſometimes their ſenſation of feeling.

In paralytic diſorders, where the uſe of a limb or limbs is taken away, the internals (recommended under the article STAGGERS) ſhould be given in order to warm, invigorate, and attenuate the blood; and the following ſtimulating embrocation ſhould be rubbed into the parts affected.

Take oil of turpentine four ounces, nerve ointment and oil of bays, of each two ounces; camphor rubbed fine, one ounce; rectified oil of amber three ounces, tincture of cantharides one ounce.

With this liniment the parts affected ſhould be well bathed for a conſiderable time, to make it penetrate; and when the hind parts are chiefly lame, the back and loins ſhould be well rubbed with the ſame: to the nervous medicines above recommended, may be added ſnake-root, contrayerva, muſtard-ſeed, horſe-radiſh root, ſteeped in ſtrong beer, or wine where it can be afforded. Take the following for an example, which may be given to the quantity of three pints a day alone, or two horns full may be taken after the nervous balls.

Take ſnake-root, contrayerva and valerian, of each half an ounce, muſtard-ſeed and horſe-raddiſh root ſcraped, of each two ounces, long-pepper two drams, infuſe in three pints of ſtrong beer or wine.

When the horſe is recovering from any of the above diſorders, the following alterative purge may be repeated two or three times, as it operates very gently.

Take ſuccotrine aloes one ounce; myrrh half an ounce; aſſa fœtida and gum ammoniacum, of each two drams; ſaffron one dram: make into a ball with any ſyrup.

Where a retention of dung is the cauſe of this diſorder, the great gut ſhould firſt be raked thoroughly with a ſmall hand, after which plenty of emollient oily clyſters ſhould be thrown up, and the opening drink given, till the bowels are thoroughly emptied of their impriſoned dung. Their diet ſhould for ſome days be opening, and conſiſt chiefly of ſcalded bran, with flower of brimſtone, ſcalded barley, &c.

PANIC, a plant reſembling millet in its ſtalks, leaves, and roots; but differing in its ſpikes, or ears, which are about the thickneſs of a man's finger at their baſe, and growing taper toward their points. They are about eight or nine inches long, and cloſely ſet with a ſmall roundiſh grain, ſometimes white, ſometimes red and purple, and ſometimes yellow. It is raiſed and reaped in the ſame manner as millet, but does not require ſo much rain. This plant grows naturally in both the Indies, and is cultivated in ſeveral parts of Europe for the food of men. Cakes and bread are made of it in Germany, Italy, and the ſouthern parts of France; but it is not reckoned ſo good nouriſhment as millet: nor is the German ſort ſo much eſteemed as the Italian; though the former ripens beſt in cold countries, where it is frequently ſowed in land which will not produce better grain. It thrives moſt in a dry ſtiffiſh ſoil, ſuch as the ſides of hills, and even in ſtony ground; grows to the height of about four foot, and branches very much; for which reaſon the horſe-hoeing huſbandry is by far the fitteſt for it. The plants, if managed rightly, ſhould ſtand at leaſt eighteen inches aſunder, in rows three feet apart, that there may be room to hoe the ground between them, and to keep them clear from weeds. When grown pretty tall, they ſhould be ſupported by ſtakes, leſt the wind break them down, and particular care muſt be taken to guard againſt birds when their ſeeds begin to ripen.

PANNAGE, the food which ſwine feed upon in woods, as acorns, and the maſt of beech. It alſo ſignifies the money taken by the king's agiſtors, for the privilege of feeding hogs in the king's foreſts.

PANNEL, a low ſaddle.

PARING *the ſole. See the article* SHOEING HORSES.

PARSNEP, the name of a plant propagated for the ſake of its roots.

Parſneps require a rich, mellow, and deep ſoil; in order that their roots, according to the bigneſs and length of which they are eſteemed, may have full room to thicken and run downward. The ſeeds of theſe plants ſhould be ſown in February or March, either alone, or with carrots, eſpecially if it be intended to draw theſe laſt very young; becauſe parſneps ſeldom ſpread much before the latter end of ſummer, by which time the carrots will, in this caſe, be gone. The practice of thoſe gardeners who ſow leeks, onions, and lettuces with their parſneps, is very wrong; becauſe ſo many different growths muſt impoveriſh one another.

The young parſneps muſt be hoed and weeded, or if they were ſown in rows, the ground between thoſe rows muſt be dug, three or four times in the ſpring, or whenever elſe many weeds appear. By the latter end of the ſummer, their leaves will cover the ground, and prevent the farther growth of weeds; ſo that they will not require any more care after that ſeaſon.

When their leaves begin to decay, their roots may be dug up for uſe: but they are ſeldom well taſted before that time; nor are they good for much late in the ſpring, after they have ſhot out again. They, therefore, who would preſerve them for ſpring uſe, ſhould dig them up in the beginning of February, and bury them in ſand in a dry place, where they will remain good until the middle of April or later.

To ſave the ſeeds of this plant in the moſt advantageous way, ſome of the longeſt, ſtraiteſt, and largeſt roots, ſhould be ſingled out, and planted about two feet aſunder, in a place where they will be defended from the ſtrong ſouth and weſt winds: for the ſtems of the parſneps generally grow to a great height, and are very apt to be broken by ſtrong guſts of wind, if they are expoſed thereto. This ground ſhould alſo be kept clear from weeds; and if the ſeaſon ſhould prove dry, watering of theſe plants moderately, twice a week, will increaſe the quantity, and improve the quality, of their ſeeds, which will be ripe about the end of Auguſt or beginning of September, when the heads ſhould be carefully cut off, and ſpread upon a coarſe cloth for two or three days, to dry. The ſeeds ſhould then be beaten off, and put up for uſe. But neither theſe nor carrot-ſeeds, ſhould be depended on after they are above a year old

Parſneps are an excellent, wholeſome, and very nouriſhing food for cattle. Their culture, as I have juſt obſerved, is exactly the ſame as that of carrots, with which they may therefore be ſown in the ſame ground. Their leaves will decay at nearly the ſame time, when the roots may be dug up, and laid by for uſe, likewiſe buried in dry ſand, in a dry place.

Parſnep-ſeeds ſeldom grow after they are above a year old.

It has long been a cuſtom in ſome parts of Britany, to ſow parſneps in the open field for the food of cattle; as we are informed by the firſt volume of the tranſactions of a Society inſtituted in that province, for the encouragement of the oeconomical and commercial intereſts of their country. "It is of great importance," ſay they, "that parſneps ſhould be univerſally cultivated; becauſe they afford an excellent and wholeſome food for all kinds of cattle, during the winter, and may be uſed to great advantage to fatten them. Our hogs have no other food in all that ſeaſon, and our bullocks and oxen thrive well upon it. Our cows fed with parſneps give more milk than with any other winter fodder, and that milk yields better butter than the milk of cows nouriſhed with any other ſubſtance. Our horſes fatten with this food: though ſome pretend that it renders them leſs mettleſome, and hurts their legs and eyes.

"Cattle eat theſe roots raw at firſt, ſliced lengthwiſe; and when they begin not to reliſh them, they are cut in pieces, put into a large copper, preſſed down there, and boiled with only ſo much water as fills up the chaſms between them. They then eat them very greedily, and continue to like them."

PARTERRE, a level diviſion of ground, which, for the moſt part, faces the ſouth and beſt front of the houſe, and is generally furniſhed with greens, flowers, &c.

There are ſeveral ſorts of parterres, as plain graſs with borders, and parterres of embroidery, &c.

PARTRIDGE, a timorous and ſimple bird, and is ſo valuable at the table, that there is a great many ways of taking it invented by the ſportſmen, all of which ſucceed from the folly and fear of the animal.

The places that partridges moſt delight in, are corn fields, eſpecially while the corn grows; for that is a ſafe retreat, where they remain undiſturbed, and under which they uſually breed. They frequent the ſame fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a ſufficient ſhelter for them under covert of the ſtalks, eſpecially of thoſe of wheat ſtubble. When the wheat ſtubble is much trodden by men or beaſt, they retire to the barley ſtubble, and will there hide themſelves in coveys of twenty or thirty. When the winter comes on, and the ſtubble fields are trodden down or ploughed up, they then retire to the upland meadows, where they lodge in the high graſs, and among ruſhes; ſometimes they reſort to the low coppice woods, eſpecially if there be corn lands near them.

PASTURE, or *Paſture Land*, a general name for all ſorts of land reſerved for the purpoſes of feeding cattle.

Paſture ground is of two ſorts: the one is low meadow land, which is often over-flowed; and the other is upland, which lies high and dry. The firſt of theſe will produce a much greater quantity of hay than the latter, and will not require manuring or dreſſing ſo often: but then the hay produced on the upland is much preferable to the other; as is alſo the meat which is fed in the upland more valued than that which is fatted in rich meadows: though the latter will make the fatter and larger cattle, as is ſeen by thoſe which are brought from the low rich lands in Lincolnſhire. But where people are nice in their meat, they will give a much larger price for ſuch as hath been fed on the downs, or in ſhort upland paſture, than for the other, which is much larger. Beſides this, dry paſtures have an advantage over the meadows, that they may be fed all the winter, and are not ſo ſubject to poach in wet weather; nor will there be ſo many bad weeds produced; which are great advantages, and do, in a great meaſure, recompenſe for the ſmallneſs of the crop.

We have already mentioned the advantages of meadow land, or ſuch as is capable of being overflowed with water, and given directions for draining and improving low paſture land, under the article LAND; therefore ſhall not repeat

peat that here, but juſt mention ſome methods for improving of upland paſture.

The firſt improvement of upland paſture is, by fencing it, and dividing it into ſmall fields of four, five, ſix, eight, or ten acres each, planting timber trees in the hedge-rows, which will ſcreen the graſs from the dry pinching winds of March, which will prevent the graſs from growing in large open lands; ſo that, if April proves a dry month, the land produces very little hay; whereas in the ſheltered fields the graſs will begin to grow early in March, and will cover the ground, and prevent the ſun from parching the roots of the graſs, whereby it will keep growing, ſo as to afford a tolerable crop, if the ſpring ſhould prove dry. But, in fencing of land, it muſt be obſerved, as was before directed, not to make the incloſures too ſmall, eſpecially where the hedge-rows are planted with trees; becauſe, when the trees are advanced to a conſiderable height, they will ſpread over the land; and, where they are cloſe, will render the graſs ſour; ſo that, inſtead of being of an advantage, it will greatly injure the paſture.

The next improvement of upland paſture is, to make the turf good, where, either from the badneſs of the ſoil, or for want of proper care, the graſs hath been deſtroyed by ruſhes, buſhes, or mole-hills. Where the ſurface of the land is clayey and cold, it may be improved by paring it off, and burning it in the manner before directed: but, if it is an hot ſandy land, then chalk, lime, marle, or clay, are very proper manures to lay upon it: but this ſhould be laid in pretty good quantities, otherwiſe it will be of little ſervice to the land.

If the ground is over-run with buſhes or ruſhes, it will be a great advantage to the land to grub them up towards the latter part of ſummer; and after they are dried to burn them, and ſpread the aſhes over the ground juſt before the autumnal rains; at which time the ſurface of the land ſhould be levelled, and ſown with graſs-ſeed, which will come up in a ſhort time, and make good graſs the following ſpring. So, alſo, when the land is full of mole hills, theſe ſhould be pared off, and either burnt for the aſhes, or ſpread immediately on the ground, when they are pared off, obſerving to ſow the bare patches with graſs ſeed, juſt as the autumnal rains begin.

Where the land has been thus managed, it will be of great ſervice to roll the turf, in the months of February and March, with an heavy wood roller; always obſerving to do it in moiſt weather, that the roll may make an impreſſion: this will render the ſurface level, and make it much eaſier to mow the graſs, than when the ground lies in hills; and will alſo cauſe the turf to thicken, ſo as to have what the people uſually term a good bottom. The graſs, likewiſe, will be the ſweeter for this huſbandry, and it will be a great help to deſtroy bad weeds.

Another improvement of upland paſtures is, the feeding of them: for where this is not practiſed, the land muſt be manured at leaſt every third year; and where a farmer hath much arable land in his poſſeſſion, he will not care to part with his manure to the paſture. Therefore every farmer ſhould endeavour to proportion his paſture to his arable land, eſpecially where manure is ſcarce, otherwiſe he will ſoon find his error; for the paſture is the foundation of all the profit which may ariſe from the arable land.

Whenever the upland paſtures are mended by manure, there ſhould be a regard had to the nature of the ſoil, and a proper ſort of manure applied: as for inſtance, all hot ſandy land ſhould have a cold manure; neat's dung and ſwine's dung are very proper for ſuch lands; but, for cold lands, horſe-dung, aſhes, and other warm manures, are proper. And when theſe are applied, it ſhould be done in autumn, before the rains have ſoaked the ground, and rendered it too ſoft to cart on; and it ſhould be carefully ſpread, breaking all the clods as ſmall as poſſible, and then harrowed with buſhes, to let it down to the roots of the graſs. When the manure is laid on at this ſeaſon, the rains in winter will waſh down the ſalts, ſo that the following ſpring the graſs will receive the advantage of it.

There ſhould alſo be great care had to the deſtroying of weeds in the paſture every ſpring and autumn: for, where this is not practiſed, the weeds will ripen their ſeeds, which will ſpread over the ground, and thereby fill it with ſuch a crop of weeds as will ſoon overbear the graſs, and deſtroy it; and it will be very difficult to root them out, after they have gotten ſuch poſſeſſion; eſpecially ragwort, and ſuch other weeds as have down adhering to their ſeeds.

Theſe upland paſtures ſeldom degenerate the graſs which is ſown on them, if the land is tolerably good: whereas the low meadows, which are overflowed in winter, in a few years turn to an harſh ruſhy graſs, though the upland will continue a fine ſweet graſs for many years without renewing.

There is no part of huſbandry, of which the farmers are in general more ignorant than that of the paſture: moſt of them ſuppoſe, that when old paſture is ploughed up, it can never be brought to have a good ſward again: ſo their common method of managing their land, after ploughing, is, to ſow, with their crop of barley, ſome graſs ſeeds, as they call them; that is, either the red clover, which they intend to ſtand two years after the corn is taken off the ground, or rye graſs, mixed with trefoil: but as all theſe are, at moſt, but biennial plants, whoſe roots decay ſoon after their ſeeds are perfected; ſo, the ground, having, no crop upon it, is again ploughed for corn: and this is the conſtant round which the lands are employed in, by the better ſort of farmers; for I never have met with one of them who had the leaſt notion of laying down their land to graſs for any longer continuance; therefore, the ſeeds which they uſually ſow, are the beſt adapted for this purpoſe.

But, whatever may have been the practice of theſe people, I hope to prove, that it is poſſible to lay down land, which has been in tillage, with graſs, in ſuch a manner, as that the ſward ſhall be as good, if not better, than any natural graſs, and of as long duration. But this is never to be expected, in the common method of ſowing a crop of corn with the graſs ſeeds: for, wherever this has been practiſed, if the corn has ſucceeded well, the graſs has been very poor and weak; ſo that, if the land has not been very good, the graſs has ſcarcely been worth ſaving: for the following year it has produced but little hay, and the year after the crop is worth little, either to mow or feed. Nor can it be expected to be otherwiſe; for the ground cannot nouriſh two crops: and, if there were no deficiency in the land, yet the corn, being the firſt, and moſt vigorous of growth, will keep the graſs from making any conſiderable progreſs; ſo that the plants will be extremely weak, and but very thin, many of them which came up in the ſpring, being deſtroyed by the corn; for, whenever there are roots of corn, it cannot be expected there ſhould be any graſs. Therefore the

graſs

graſs muſt be thin, and, if the land is not in good heart, to ſupply the graſs with nouriſhment, that the roots may branch out after the corn is gone, there cannot be any conſiderable crop of clover: and, as their roots are biennial, many of the ſtrongeſt plants will periſh ſoon after they are cut; and the weak plants, which had made but little progreſs before, will be the principal part of the crop for the ſucceeding year: which is many times not worth ſtanding.

Therefore, when ground is laid down for graſs, there ſhould be no crop of any kind ſown with the ſeeds; and the land ſhould be well ploughed, and cleaned from weeds; otherwiſe the weeds will come up the firſt, and grow ſo ſtrong, as to overbear the graſs, and, if they are not pulled up, will entirely ſpoil it. The beſt ſeaſon to ſow the graſs ſeeds upon dry land is about the middle of September, or ſooner, if there is an appearance of rain: for the ground being then warm, if there happen ſome good ſhowers of rain after the ſeed is ſown, the graſs will ſoon make its appearance, and get ſufficient rooting in the ground before winter; ſo will not be in danger of having the roots turned out of the ground by froſt, eſpecially if the ground is well rolled before the froſt comes on, which will preſs it down, and fix the earth cloſe to the roots. Where this hath not been practiſed, the froſt has often looſened the ground ſo much, as to let in the air to the roots of the graſs, and done it great damage; and this has been brought as an objection to the autumnal ſowing of graſs: but it will be found to have no weight, if the above direction is practiſed: nor is there any hazard of ſowing the graſs at this ſeaſon, but that of dry weather, after the ſeeds are ſown; for, if the graſs comes up well, and the ground is well rolled in the end of October, or the beginning of November, and repeated again the beginning of March, the ſward will be cloſely joined at bottom, and a good crop of hay may be expected the ſame ſummer. But, where the ground cannot be prepared for ſowing at that ſeaſon, it may be performed the middle or latter end of March, according to the ſeaſon's being early or late; for, in backward ſprings, and in cold land, we have often ſowed the graſs in the middle of April, with ſucceſs: but there is danger, in ſowing late, of dry weather, and eſpecially if the land is light and dry; for we have ſeen, many times, the whole ſurface of the ground removed by ſtrong winds at that ſeaſon; ſo that the ſeeds have been driven in heaps to one ſide of the field. Therefore, whenever the ſeeds are ſown late in the ſpring, it will be proper to roll the ground well ſoon after the ſeeds are ſown, to ſettle the ſurface, and prevent its being removed.

The ſorts of ſeeds which are the beſt for this purpoſe, are, the beſt ſort of upland hay-ſeeds, taken from the cleaneſt paſtures, where there are no bad weeds: if this ſeed is ſifted to clean it from rubbiſh, three buſhels will be ſufficient to ſow an acre of land. The other ſort is the *trifolium pratenſe album*, which is commonly known by the names white Dutch clover, or white honeyſuckle graſs. Eight pounds of this ſeed will be enough for one acre of land. The graſs ſeed ſhould be ſown firſt, and then the Dutch clover-ſeed may be afterwards ſown: but they ſhould not be mixed together; becauſe the clover-ſeeds, being the heavieſt, will fall to the bottom, and conſequently the ground will be unequally ſown.

When the ſeeds are come up, if the land ſhould produce many weeds, theſe ſhould be drawn out before they grow ſo tall as to overbear the graſs: for where this has been neglected, the weeds have taken ſuch poſſeſſion of the ground, as to keep down the graſs, and ſtarve it; and, when theſe weeds have been ſuffered to remain until they have ſhed their ſeeds, the land has been ſo plentifully ſtocked with them, as intirely to deſtroy the graſs: therefore it is one of the principal parts of huſbandry, never to ſuffer weeds to grow on the land.

If the ground is rolled two or three times, at proper diſtances after the graſs is up, it will preſs down the graſs, and cauſe it to make a thicker bottom: for, as the Dutch clover will put out roots from every joint of the branches which are near the ground, ſo, by preſſing down of the ſtalks, the roots will mat ſo cloſely together, as to form a ſward ſo thick as to cover the whole ſurface of the ground, and form a green carpet; and will better reſiſt the drought. For, if we do but examine the common paſtures in ſummer, in moſt of which there are patches of this white honeyſuckle graſs growing naturally, we ſhall find theſe patches to be the only verdure remaining in the fields. And this, the farmers in general acknowledge, is the ſweeteſt feed for all ſorts of cattle; yet never had any notion of propagating it by ſeeds: nor has this been long practiſed in England; for, till within a few years that ſome curious perſons imported the ſeed from Brabant, where it had been long cultivated, there was not any of the ſeeds ſaved in England: though now there are ſeveral perſons who ſave the ſeeds here, which ſucceed full as well as any of the foreign ſeeds which are imported.

As the white clover is an abiding plant, ſo it is certainly the very beſt ſort to ſow, where paſtures are laid down to remain: for as the hay-ſeeds which are taken from the beſt paſtures, will be compoſed of various ſorts of graſs, ſome of which may be but annual, and others biennial; ſo, when thoſe go off, there will be many and large patches of ground left bare and naked, if there is not a ſufficient quantity of the white clover, to ſpread over and cover the land. Therefore, a good ſward can never be expected, where this is not ſown: for in moſt of the natural paſtures we find this plant makes no ſmall ſhare of the ſward; and it is equally good for wet and dry land, growing naturally upon gravel and clay, in moſt parts of England: which is a plain indication how eaſily this plant may be cultivated, to great advantage, in moſt ſorts of land throughout this kingdom.

Therefore, the true cauſe why the land which has been in tillage, is not brought to a good turf again, in the uſual method of huſbandry, is, from the farmers not diſtinguiſhing which graſſes are annual from thoſe which are perennial: for, if annual or biennial graſſes are ſown, theſe will of courſe ſoon decay; ſo that, unleſs where ſome of their ſeeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. Therefore this, with the covetous method of laying down the ground with a crop of corn, has occaſioned the general failure of increaſing the paſture in many parts of England, where it is now much more valuable than any arable land.

After the ground has been ſown in the manner before directed, and brought to a good ſward, the way to preſerve it good is, by conſtantly rolling the ground with an heavy roller, every ſpring and autumn, as hath been before directed. This piece of huſbandry is rarely practiſed by farmers: but thoſe who do, find their account in it; for it is of great benefit to the graſs. Another thing ſhould alſo be carefully performed; which is, to cut up docks, dandelion,

dandelion, knapweed, and all ſuch bad weeds, by their roots every ſpring and autumn: this will increaſe the quantity of good graſs; and preſerve the paſtures in beauty. Dreſſing of theſe paſtures every third year is alſo a good piece of huſbandry; for otherwiſe it cannot be expected the ground ſhould continue to produce good crops. Beſides this, it will be neceſſary to change the ſeaſons of mowing, and not to mow the ſame ground every year; but to mow one ſeaſon and feed the next: for, where the ground is every year mown, it muſt be conſtantly dreſſed, as are moſt of the graſs grounds near London, otherwiſe the ground will be ſoon exhauſted. *Miller's Gard. Dict.*

The following Methods of improving wet Paſtures, will, we doubt not, be very acceptable to our Readers, as they are founded on Experience, and conſequently have no tendency to deceive the Huſbandman.

"As I have, ſays our ingenious huſbandman, within a few years, not only had ſome experience in my own farm, but obſerved the methods employed by many neighbouring gentlemen and farmers in mending their paſtures, I ſhall communicate a few of my remarks to you on the improvement of wet paſtures; a ſubject which may prove, perhaps, of ſome little utility, as I ſhall ſpeak of nothing but what I have either performed myſelf, or ſeen hereabouts.

"The particular lands of which I ſpeak are looſe, woodcock, brick-earth ſoils for about eighteen or twenty inches, and under that, clay to a great depth.

"Some that I have improved myſelf were exactly level, ſo as to be quite poiſoned with the wet, which could not drain off.

"From the beſt obſervations I could make on many experiments, the following is the method which anſwers beſt to improve them. I ſhall alſo give you the expence with us.

"The firſt thing to be done is, to make large, deep ditches round every field, and, if the fields are large, to divide them into ſmaller, of five, ſix, or ſeven acres each, by new ditches; nothing is attended with a more ſudden improvement of all the ground near the borders of the fields, than good ditches.

"I generally make mine ſix feet perpendicular deep, ſeven wide at top, and three at the bottom. I never pay for them by the rod (which is cuſtomary) but give twopence halfpenny per load, of thirty buſhels, for all the clay, &c. that is thrown out of them, and two ſhillings and ſixpence a ſcore loads for filling and ſpreading it.

"Theſe ditches ſhould be made in ſuch a manner that no water can remain in them, but a deſcent from one to another to carry it quickly off.

"It may be eaſily imagined how much theſe muſt drain the land, beſides the quantity of excellent manure (clay) which ariſes out of them. Add to this the great convenience of having ſuch fences about a farm, that the farmer is ſure to find his cattle wherever he turns them, inſtead of their breaking perpetually into his corn or hay fields, which, in multitudes of farms, is ſo often the caſe: it is ſometimes the work of a boy, only to be hunting after hogs and ſheep that go aſtray for want of good fences.

"In the banks of new ditches we always lay white thorn, fifty roots to a rod (the workmen are allowed ſixpence per hundred for gathering them;) but I always avoid intermixing any thing with it, eſpecially haſel, for in the nut ſeaſon fences are pulled in pieces for the fruit by all the boys and girls in the neighbourhood; and oak, aſh, &c. only give an opportunity to get over the hedge with greater eaſe. Sallow, willow, elder, &c. are to be avoided in the hedge, or by way of hedge ſtake for the dead hedge, as they grow ſo faſt as quite to overſhadow the quick, and even deſtroy it. After frequent cuttings, to render the plants thick and ſtrong, I keep the quick regularly clipped, which, in a few years, renders the fence impenetrable to man or beaſt, conſidering the largeneſs of the ditch.

"If an old fence is grown bad and thin, or compoſed of improper plants, I never yet obſerved it improved by planting quick in the gaps: the beſt way is, to reverſe the bank, and plant freſh quick.

"One advantage ariſing from good fences is not apparent at firſt ſight. To the diſgrace be it ſpoken of moſt of the gentlemen of large fortunes round Bury, the game is wretchedly deſtroyed by poachers, who take it with night-nets. Theſe vermin, who are generally labourers, ſwarm in every village round me. Their method is this: they take the farmer's horſes out of his fields, and, after their doing a hard day's work, ride them all night, as faſt as they can make them go, over the ſtubbles, to catch the partridges, blundering over every hedge (except ſuch as I have deſcribed) in their way, oftentimes ſtaking the horſes (of which two inſtances have I ſeen this ſeaſon) making gaps in the fences, riding over ſtanding corn, clover for ſeed, or any thing that is a cover for birds, and, after damaging the farmer in a moſt ſhameful manner, carry the produce of their infamous labour to many, who, to their great diſhonour, encourage theſe raſcals for their convenience. The money they get is ſpent at the next alehouſe, and inſtead of doing the farmer a good day's work, they are drunk, aſleep, or idle, the whole day.

"Now there are very few farmers horſes that will leap a gate; but moſt will plunge through ſuch hedges as are common hereabouts: none could paſs ſuch ditches as I always make and recommend. A farmer in this pariſh has ſo effectually fenced in his fields with prodigious ditches, that I have heard him declare, that not a ſingle night-netter has been on his grounds on horſe-back; and were they to attempt it, they would loſe more time in paſſing one ditch than was neceſſary to drag ſome whole farms.

"The pernicious effects, to farmers, of this abominable practice, are notorious, and cry aloud for redreſs: if they would eaſe themſelves, I know of no way but ſuch ditches as I have deſcribed.

"But to return.

"When the ditching is done, the next work is to land-drain the whole fields in ſuch a manner that every part of them may be laid dry. In a paſture of ſix acres I did two hundred rod. If there is the leaſt fall in any part, or any place more wet than others, the drains ſhould be cut through them. If the ſurface is exactly level, the depth of the drains ſhould vary, ſo that the water may every where have a deſcent.

"Theſe drains are made, in general, thirty-two inches deep, twenty inches wide at the top, and four wide at the bottom. They are filled eight inches deep with either ſtones or wood; but I ſhould ever recommend

mend the former, as the moſt effectual and laſting, to thoſe who are not deſirous of ſaving the difference of the expence. However, I know many fields in this pariſh and neighbourhood that are drained with wood, and which anſwer extremely well; and I have been aſſured that they will laſt twenty or thirty years. Nay, in ſome parts of Eſſex I hear they do it with ſtraw alone; but this muſt be of ſervice for only a few years: if ſtone be uſed, there can be no doubt of its laſting. The labour of the whole is three-pence per rod; ſometimes it is done for two-pence halfpenny.

" If with ſtone of the farmers, a load of thirty buſhels will do three rods, which coſts one ſhilling and a halfpenny ſtubbing and picking; ſo the expence of a rod is ſeven-pence, beſides carriage of the ſtone, which will not be much: but if he buys his ſtone, as is much the moſt probable in this country, we may ſuppoſe he muſt go two miles to fetch it, and give a ſhilling for eighteen buſhels ready picked: the carriage is worth a ſhilling more, and reckoning the eighteen buſhels to do a rod and half (which is near the matter) the ſtone of it will coſt per rod one ſhilling and four-pence.

" If buſhes are uſed, a load of forty faggots will coſt if he buys them, or be worth if he has them, five ſhillings, and coſt cutting one ſhilling. They will do ten rods; ſo that the whole expence of doing a rod with them will be ten-pence, and of ſtone one ſhilling and ſeven-pence.

" The very firſt year the prodigious advantage of theſe drains appears, eſpecially if the ſeaſon proves wet. The graſs (or corn if in ploughed fields, for it anſwers in all) will be freſh, vigorous, and ſweet, wherever the paſtures are drained.

" I have a field of ſix acres (mentioned above) which by land-draining, ditching, and manuring, is an exceeding good paſture, and has produced two tons and ten hundred weight of hay per acre, in a very good year, and generally thirty-five hundred weight per acre; whereas the paſtures adjoining are ſcarce worth the farming, and let but at ſeven ſhillings per acre, producing ſcarce any thing but a little feed for lean cattle. The ſoil is the ſame in both; the ſix acres, about twelve years ago, being full as bad as the reſt.

" To improve ſuch wet land, nothing can be more advantageous than the clay which is thrown out of the ditches. Eighty loads per acre is the quantity I have laid on, and have been told by ſeveral ſenſible farmers (who clay a good deal) that it is a proper covering; but if nothing is mixed with it, ninety-five or one hundred. I know a piece of graſs land greatly improved, on which were ſpread one hundred and fifty loads.

" My method is to make a large hill of manure, by firſt laying a quantity of clay regularly on a heap; then placing a thin layer of muck, ſuch as I have, upon it, either my ſtable or raek-yard dung, or bringing it of any kind in my waggon from Bury; on this layer, another thick one of clay; then the ſecond of dung, and ſo on; letting the proportion be about twenty loads of dung to fifty of clay. Theſe heaps, after remaining ſix months without ſtirring, I mix well together by turning them over, which a workman will do at the rate of eight ſhillings for one hundred loads. Let it lie ſix months longer in this ſtate, and then carry it on to the land, paying two ſhillings and ſixpence per ſcore loads for filling and ſpreading. This I take, from experience, to be by much the beſt way of manuring with clay, as it works and impregnates the ſoil much ſooner than alone.

" Whenever I clay arable land, I do it on clover paſtures after the crop of corn is off, managing it in the ſame manner as for paſtures. If it is ploughed in directly, it is ſeveral years before it works; but having a winter and ſummer to diſſolve and powder it, it waſhes in to the ſoil more equally, and in a properer ſtate for improvement. *See the article* CHALK.

" Theſe are the principal points to be obſerved in improving ſuch wet, cold, looſe, paſtures as I have deſcribed: ſome that I have quite changed by theſe means were half over-run with moſs and ruſhes; but draining them thoroughly, and claying them, kills all rubbiſh of this ſort, and preſents the farmer with ſo admirable a view of good paſture for dairy or grazing, where ſo lately nothing could live, as to be equalled in ſcarce any thing of the kind.

" But as all improvement ceaſes to be ſuch when more money is ſpent in it than the advantages will repay, I ſhall in a few words diſplay how far this is from being the caſe here. I will ſuppoſe two or three fields are improved by claying and draining, amounting in the whole to twenty acres.

	l.	s.	d.
" Sixty loads of clay per acre thrown out of the ditches, twelve hundred loads, at two-pence halfpenny per load —— ——	12	0	0
" I will ſuppoſe ſixty rod of new ditching done, which, before clay is thrown out by the load, will coſt one ſhilling per rod ——	3	0	0
" Three thouſand quickſets, at ſixpence per hundred —— ——	0	15	0
" Land-draining ſeven hundred rod with buſhes (this is the quantity I have now marked out in a field of twenty acres) at ten-pence per rod	29	3	4
" N. B. I had a great part of my laſt crop of barley killed in this field with the wet: I had therefore a fine opportunity of marking exactly where the drains ſhould be made, which ought, on ſuch occaſions, never to be omitted, were it only for the common water-furrows which are made for every crop. In ſome fields, unleſs ſuch a guide offers, it is very difficult to tell exactly where to make the land-drains.			
" Turning and mixing one thouſand ſix hundred load of manure —— —	6	8	0
" Filling and ſpreading one thouſand ſix hundred loads, at two ſhillings and ſixpence per ſcore	10	0	0
" I will ſuppoſe that the work may be done the ſooner if the farmer brings one hundred loads of the four hundred of dung from the neareſt town; and as I have not reckoned the horſes and driver for the clay cart, I ſhall not in the bringing the dung: therefore the expences per waggon load will be, the coſt three ſhillings, boy ſixpence, and turnpike ſixpence. A waggon load is two tumbrel loads (in this country) ſo fifty loads, at four ſhillings, are	10	0	0
Total	71	6	4

" This

"This is three pounds eleven ſhillings and three-pence per acre: and ſuppoſing the profit to laſt but twenty years, although the draining and ditching part will laſt twice that time, and the clay five and twenty as good as at firſt; and the farmers hereabouts ſeldom change their farms, if tolerable ones, living in them their lives, and their ſons after them, with leaſes of ſeventeen, twenty-one, and twenty-five years: ſuppoſing twenty years profit, I ſay, the expences will then be, per acre per annum, three ſhillings and ſixpence halfpenny.

"So ſmall is the expence divided. But now let us conſider the profit.

"Such land as I have deſcribed never lets here for more than ten ſhillings per acre, by far oftener for eight ſhillings, or eight and ſixpence; and it is from my own experience, as well as various obſervations, that I aſſert the ſame land, after the improvements, will let to any tenant for ſeventeen, eighteen, and twenty ſhillings per acre.

"I will ſuppoſe it only ſixteen ſhillings, though I am certain that is conſiderably under the mark: he then gains, in point of rent, ſix ſhillings per acre; and the whole calculation is abſurd, if we do not add his whole proportional profit on the acre: ſuppoſing his profit on it before improvement was a rent, ten ſhillings; afterwards, it will undoubtedly be the ſame at leaſt; which adds ſix ſhillings more to the profit; ſo that the whole will be twelve ſhillings per acre per annum, or eight ſhillings and ſixpence clear, after the improvement is paid.

	l.
"Twelve ſhillings per acre is per annum, for twenty years	240
"Expences of improvement	71
"Clear profit	169

"Or eight pounds nine ſhillings per annum: and if we reckon five per cent. intereſt for the ſeventy-one pounds, that is, three pounds eleven ſhillings per annum, which, deducted from eight pounds nine ſhillings, leaves four pounds eighteen ſhillings per annum abſolute profit.

"Thus, I think, I have ſtated the caſe of this improvement clearly; and I muſt repeat it, that I ſpeak from experience. The ſum to be expended on twenty acres will appear large to moſt farmers, whoſe property is not conſiderable; but the proportion holds for a ſingle acre, and thoſe who cannot afford to improve twenty, may three, four, or five; and I make no doubt but ſuch as attempt it will find their account in it greater than I have ſtated it.

"As I have mentioned a tumbrel-load to be thirty buſhels, and a waggon load to be but two tumbrels, I ſhould obſerve that we carry away of muck fifty buſhels at a time in our tumbrels, and ſo agree with our men in proportion to the thirty buſhel loads.

"I have obſerved, that in making new ditches, or enlarging old ones, I never pay by the rod, but by the load: however, to thoſe who chuſe the former way, I would recommend that they have them worked by a frame of ſmall ſlit deal, nailed into the exact ſize of the intended ditch, and agree with the workmen to do their work by it: this will prevent diſputes which frequently ariſe."

PATE, a brock or badger.

PEASE, a genus of plants cultivated in every part of England both in the field and kitchen-garden. We ſhall here give the beſt inſtructions in our power for obtaining large crops in the field.

Mr. Liſle, for the greater eaſe and more certain guidance of country people, who are apt to be perplexed by a long liſt of particular names of different ſorts of field-peas, and of their ſeveral numerous varieties, judiciouſly ranges them under two general heads, viz. the tender and the hardy ſmall ſort, and the tender and the hardy great ſort; under the one or the other of which claſſes he thinks all kind of peas may properly be ranked, becauſe they equally agree or diſagree with the ſame ſoil. The tender pea, for example, is improper for a cold country, or, which amounts to the ſame, for cold ground in a warm country; and the large pea, by reaſon of its great haulm, is not proper for ſtrong rich land, becauſe its haulm will there increaſe to ſo great a length, that it will not be able to bear pods. His own experience in the year 1704, ſatisfied him fully that the beſt way to make peas pod well, is to ſow them on a mellow mould, rendered light by plowing: and he thinks it right to roll the ground ſoon after they are ſown.

Even the moſt general directions cannot but be of ſervice to the huſbandman: but more particular obſervations and actual experiments properly diverſified, are ſtill much wanted in the culture of this, and indeed of all other podded grains, and ſucculent plants, whoſe importance, as deſtroyers of weeds, improvers of land, and excellent preparers of it for other crops, is eſtabliſhed beyond diſpute. It is even a rule with farmers, not to ſow the ſame land a ſecond time with peas, till ſix, or at leaſt five years after the former crop of the ſame kind; becauſe, till then, the ground on which they grew will continue ſo rich as to make them run luxuriantly to haulm, in a manner inconſiſtent with the bearing of much fruit.

The common white pea does beſt on light ſandy land, or on a rich looſe ſoil. It is generally ſown with a broad caſt, and only harrowed in. Three buſhels of theſe peas are the uſual allowance of ſeed for an acre of ground; and the common time for ſowing them is about the latter end of March, or the beginning of April, on warm land: but a fortnight or three weeks later than this, will be early enough on cold ground. If ſown in drills, which is by far the beſt way, a buſhel and a half of ſeed will be full enough for an acre; and, when they are thus ſet regularly, the ground may be ſtirred with a hoe, to deſtroy the weeds, and earth up the plants, by which they will be greatly improved, and the peas will be much eaſier to cut in autumn, when they are ripe.

The green and the maple rouncivals require a ſtronger ſoil than the white, and ſhould be ſown a little later in the ſpring, alſo in drills, but farther aſunder, that is to ſay, at the diſtance of at leaſt two feet and a half, or three feet from each other, becauſe they are apt to grow rank, eſpecially in a wet ſeaſon. The ground between theſe rows ſhould be ſtirred two or three times with a hoe, which will not only deſtroy the weeds, but, by earthing up the peas, will greatly improve them, and alſo render the land fitter to receive whatever crop is put on it the following ſeaſon.

The gray and other large winter peas, as they are called, are ſeldom cultivated in gardens, becauſe they require a great deal of room. The beſt time for ſowing of theſe is about the beginning of March, when the weather is pretty dry; for if they are ſown in a very wet ſeaſon, they are apt to rot, eſpecially if the ground be cold. The diſtance between

between the rows ſhould here be at leaſt three feet, and theſe peas ſhould be ſown very thin in the rows: for if they are ſown too thick, their haulm will ſpread ſo as to fill the ground, and they will ramble over each other; by which means many of the plants will be rotted, and hindered from bearing. The common allowance of theſe large peas, is two buſhels to an acre: but that is certainly more than conſiſts with the very thin ſowing which is beſt for them.

The gray peas, in particular, thrive beſt on a ſtrong clayey land, in which they are commonly ſown under furrow. But by this method of ſowing, large peas, eſpecially, are always planted too thick, and at unequal depths, which prevent their coming up regularly. For this reaſon, among many others, all rank-growing plants, ſhould undoubtedly be ſown in drills, in which their ſeeds will be diſtributed much more equally in all reſpects.

If only a ſmall ſpot of ground be planted with theſe peaſe, a channel about two inches deep may be made with a hoe, guided by a line, the ſeeds may be dropped therein, and the earth may be drawn over them with a rake. By this means they will be covered equally, and with tolerable diſpatch, though not ſufficient for large fields, where, for this reaſon, a ſhallow furrow is commonly made with the plough, the ſeeds are ſcattered in it, and the earth is harrowed over them. The greateſt trouble then remaining is to keep the plants clear from weeds, and lay the earth up to their roots, which, in countries where labour is dear, is very expenſive to have done with the hand-hoe, but may be eaſily effected by drawing a horſe-hoe between the rows. This will entirely eradicate the weeds, ſtir the ſoil, render it mellow, and greatly promote the proper growth of the plants.

All ſorts of peaſe love limed or marled land: but when they are ſown late in the ſeaſon, the ſoil ſhould be ſtrong and moiſt; for they will then burn up and periſh in hot light land, or at leaſt not produce a crop worth taking off the ground. The authors of the *Maiſons Ruſtiques* approve of ſteeping them twenty-four hours in water before they are ſown, as well as to ſeparate the bad and faulty from the good, to enable theſe laſt to riſe the ſooner by being thus moiſtened. In general, the larger the pea is, and conſequently the later its uſual time of ripening, the earlier it ſhould be ſown, as experience has directed, and as Mr. Liſle rightly infers from the following curious obſervation, which, if duly attended to, may be of ſervice to huſbandmen and gardeners, and perhaps productive of ſome improvement in the culture of this plant.

In 1708, when the field and garden peaſe were near a foot high, he obſerved on the very top of them a purſe or neſt of buds of bloſſoms, lying in a bag together; and perceiving at the ſame time that there was no ſhew of bloſſoms putting forth at the lower joints, he concluded that the crops of peaſe would miſcarry that year, that they would not only have ſome top-kid, and that it would be vain to expect any on the lower joints, becauſe they are always forwarder in bloſſoming and kidding than the upper joints, and had not then the leaſt appearance of doing either. This afforded him ſome amuſements in reaſoning: but, not being ſatisfied, in a day or two after looked again into theſe upper pods or bags of bloſſoms, and upon diſſecting a number of them, found ſometimes in a ſingle one near thirty bids of bloſſoms, two or three of which ſeemed uſually to have got the ſtart of the reſt, and to be bigger in bulk, and taller: moſt of the reſt ſeemed to lie in a huddle, without making any gradations: but as he had never ſeen, excepting the crown pea (which carries all its bloſſoms in a tuft at top, like a noſegay) other peas put forth above two bloſſoms and kids at top, which ſeldom come to any good, he ſuſpected that the many bloſſoms in this pod, muſt form the ſucceſſive gradations of bloſſoming joints, ariſing from that ſtock as from a common root, and that every bloſſom ſhot forth in order, as it grew forwarder than the reſt, while the main ſtem, advancing higher and higher, left behind the ſubaltern bloſſom of a lower joint. To be clear in this, he tied ſcarlet threads juſt under ſeveral of theſe pods, that he might know them again, and, as he expected, found in four or five days time a gradation of bloſſoms ariſing from joints with lobous leaves above his ſcarlet threads, and the pod of bloſſoms ſtill advanced on to the end, leaving behind farther joints of bloſſoms, till the whole ſtock was ſpent.

From this obſervation Mr. Liſle infers, 1. That by looking into this pod, or purſe of buds, while it is yet ſo much in its infancy as only to be viewed by a magnifying glaſs, we may judge what hopes there are of a future crop, provided the ſucceeding months prove favourable: and, 2. That we may learn from thence what ſort of peaſe to adopt to every ſort of ground: "but, continues he, before I enter on this part and uſe of the above-mentioned obſervation, I muſt, for the better underſtanding thereof, premiſe, that the farmers vary in their judgment in no one point ſo much as in the nature of the pea. Several ſorts of peaſe are commonly ſown within the limits of the ſame pariſh, and each of the perſons who ſow them generally has a great prejudice to any other ſort than that which he ſows, having perhaps been diſappointed of his expected return from other peaſe, when he has ſowed them, and being, for the ſame reaſon, equally diſpoſed as readily to alter his opinion of his laſt favourite kind; for the produce of a crop of peaſe is always very uncertain. But if the farmer would conſider, from the foregoing obſervation, how early or rath-ripe a pea is, or how late in ripening, in its nature; and that (as all its ſtock or power to put forth bloſſoms lies within the foliage of one pod) the art muſt reſult from thence, ſo to ſow the peaſe, in ſuch ground, and at ſuch time, that each ſort of pea, according to its nature, may, before autumn and cold weather come to check them, ſend forth all its gradations of joints or bloſſoms, ſo that none may become abortive for want of ſummer enough to enable nature to bring her embrios to maturity, and carry the bud-bloſſoms into kids; then it is apparent (as all large peaſe ripen late, and run to great haulm or ſtalks, and ſmall peaſe have leſs haulm and ripen earlier) that the great or late ripe peaſe ſhould be ſowed as early as the climate will permit; for thereby ſuch pea will get ſo forward as to have time to put forth all its gradations of bloſſoms and kids, and to perfect them before a rainy autumn comes, and puts a ſtop to farther vegetation. Again, great peaſe ought to be ſowed on a white, or ſome mixed land, not too groſs of juice; but not on a cold clay: for the moiſture of this laſt will keep feeding the haulm, and be inconſiſtent with the main deſign of ſowing them early, which is, that they may bring all their fruit to maturity in due time. The white or mixed mould muſt be in good heart; for otherwiſe it cannot maintain a great pea. On the other hand, it is evident from hence that a pea which ripens early ſhould be ſowed in a ſtrong feeding land, becauſe ſuch land will nouriſh it more vi-

gorouſly, without danger of too great an increaſe of its haulm, which is naturally ſhort; and, notwithſtanding the coldneſs of the ſoil, there need be no doubt but that all the kids will ripen."

Moderate rains are of ſingular ſervice to peaſe while they grow, and particularly at their time of bloſſoming and filling up their pods; but a continuance of cold rain for many days, is perhaps as prejudicial as too much heat or drought. The bluiſh bloom upon their leaves, and their expanding backward the two outermoſt and largeſt leaves of their bloſſoms, are undoubted ſigns of great health and vigour. Mr. Liſle is of opinion, that they neither ripen nor harden ſo well upon high grounds, as in the vallies, and conſequently that the former are not ſo fit for keeping as the latter.

Among the very few experiments on the culture of peaſe in field, the following which M. Duhamel has given, afford a pretty ſtrong conviction of the benefits which ariſe from horſe-hoeing between their rows.

In April 1753, M. de Villiers, one of that ingenious gentleman's correſpondents, ſowed a ſmall field in Champagne, with peaſe in double rows. Not being provided with a proper inſtrument to hoe the intermediate ſpaces, he made uſe of a narrow angular kind of ſhare, which ſtirred only three or four inches on the outſide of the rows. Almoſt all the peaſe in his neighbourhood were deſtroyed that year by a kind of vermin called vine-fretters. His were hurt the leaſt of any; which was probably owing to the greater vigour of the plants, or the inſects being killed by the ſtirring of the ground. By a compariſon which he made of the produce of this ſpot, he found that it yielded ſix times as much as the ſame extent of the beſt land in the ſame country. "In a good year, ſays M. Duhamel, the difference would not have been ſo great; but ſtill this experiment ſhews that plants cultivated in the new or horſe-hoeing way, are better able to reſiſt the inclemencies of the ſeaſons, and other accidents, than thoſe which are cultivated according to the old method."

The next year, M. de Villiers, being provided with M. Duhamel's drill and horſe hoe, ſowed peaſe again in rows, in ſome places two feet, and in others two feet and a half aſunder. But this diſtance was ſo narrow that it rendered the horſe-hoeing very difficult in many places, and quite impracticable in others. He was therefore obliged to contrive other means of ſtirring the ground, in which, notwithſtanding this, his peaſe flouriſhed extremely, and yielded more than any others on the very beſt land in the ſame diſtrict.

The ſame gentleman drilled peaſe again, in 1755, in a ſtrong heavy ſoil, in which no one had ever ventured to ſow any in the common huſbandry. They grew as high as if the ground had been ever ſo fit for them, and yielded half as much again as any ſown in the common way, beſides the ſaving in the ſeed, which in peaſe thus drilled, is about one half. They were ſown in double rows, with a ſpace about two feet and a half wide between the outmoſt rows of one range and the next outmoſt row of another, and this ſpace was ſtirred with the horſe-hoe.

When any particular ſorts of peaſe are intended for ſeed, they ſhould be carefully looked over whilſt in flower, in order to draw out all ſuch plants as are not of the right ſort; for there will always be, in every ſort, ſome roguiſh plants, as the gardeners term them, which, if left to mix, will degenerate the kind. As many rows as may be thought ſufficient to furniſh the deſired quantity of ſeed, ſhould then be marked out, and left till their pods turn brown and begin to ſplit, when they ſhould immediately be gathered up, with the haulm; and if the huſbandman has not room to ſtack them till winter, they may be threſhed out as ſoon as they are dry, and put up in ſacks for uſe: but particular care ſhould be taken not to let theſe remain too long abroad after they are ripe, becauſe wet would rot them, and heat, after a ſhower of rain, would make their pods burſt in ſuch a manner that the greater part of their ſeeds would be loſt.

When peaſe are reaped, or hacked, as they call it in ſome parts of England, they are laid up in ſmall wads, and left in the field till the haulm and pods are dry: but during this time they ſhould be frequently turned, and raiſed as much as poſſible from the earth, that they may lie hollow for the wind to dry them, eſpecially when any rain happens to wet and beat them down. In Leiceſterſhire they ſet all their peaſe abroad in ſtacks, being perſuaded that they thence acquire a much better colour, than when houſed in a barn.

An ingenious farmer has obliged the public with the following method of preparing peaſe for hog-meat; and which we ſhall here give in his own words.

"A few years ago, ſays he, I had a plentiful crop of peaſe on a ten acre piece, which lies near my houſe: when they were full podded and nearly ripe, I had them hooked in the uſual manner; but before I could get them in, there came a heavy ſhower of rain, which wetted them through and through; and the dull heavy weather, with frequent ſhowers, which followed, prevented their drying for a conſiderable time.

"I cauſed the wads to be from time to time turned, to prevent the haulm from rotting; and at length a few days ſunſhine dried them enough to be inned; for as they lay hollow, the wind was greatly aſſiſtant to the operation.

"Before I got them in, on examining ſome of the pods, I found that the peaſe were all ſprouted to a conſiderable length: this was what I had expected, as I gave my crop over for loſt, till after a little recollection, as the weather ſtill continued fine, I determined to threſh them in the field.

"This was accordingly done; and the corn, after it was caſt and riddled to ſeparate it from the rubbiſh, was dried on my malt-kiln.

"When this operation was over, I began to reflect in what manner I ſhould diſpoſe of my peaſe, being ſenſible that they could not be proper for ſeed, and ſtanding no chance of diſpoſing of them to any advantage in the market.

"At length, as it was then a time of war, and of courſe there was a great demand for pork for the uſe of the navy, I determined to buy a conſiderable number of lean hogs, that I might by their means conſume this crop on my own premiſes, and in that manner make the moſt of it.

"My expectations were more than anſwered, for I found, by repeated experience, that three buſhels of the peaſe I have mentioned went nearly as far in fattening the hogs I bought, as four buſhels got in dry and hard in the manner uſually practiſed.

"This diſcovery I made ſeveral years ago, and it has turned out to my advantage, for ſince that time, I have been quite indifferent as to the weather in which my peaſe are hooked, being rather better pleaſed, as far as relates to them, with wet, than dry weather: but if the weather happens

pens to be dry at the time they are ripe, I always cauſe as many as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the ſame manner, nearly as my barley: this management has of late ſucceeded very well with me, and I therefore intend to continue it.

" Beſides feeding my hogs with theſe malted peaſe, I have beſides often given them to my horſes, with which they agree very well, and are heartening food.

" Turkeys will fatten apace on them alſo, and be fine meat.

" I have applied my malted peaſe to many other uſes, which I have not, at preſent, time to enumerate: but were they only uſed for feeding hogs and horſes, it is ſtill worth while to prepare ſome in this manner every year." *Muſeum Ruſticum, vol.* I. *page* 109.

PEASE-BOLT, peaſe haulm.

PEAT, a ſpecies of earth uſed in many countries for firing.

Under the article ASHES we have given ſome account of the uſes of thoſe made from peat; and ſhall here add the obſervations of a very intelligent huſbandman, with regard to the value of thoſe aſhes, and the ſeveral crops to which they may be profitably employed as a manure.

" The more general, ſays he, a manure is in its uſes, of ſo much the more value is it to the farmer; and, of all ſorts of manures, perhaps aſhes agree with the greateſt variety of ſoils and crops: aſhes, therefore, ſhould, one would imagine, be had in univerſal requeſt, for the purpoſe of dreſſing land; but the misfortune is, no great plenty can be procured, and the few that are to be got fetch a large good price: this deters the farmer for making uſe of them often as manure.

" I muſt, however, except one ſort of aſhes which are on all accounts valuable; I mean peat or turf-aſhes: theſe are, in moſt places, eaſy to be procured, coſt no great matter, and have a wonderful effect on almoſt every ſoil and crop. You may believe what I ſay, as I have had many years experience of their good qualities.

" Theſe ſulphureous and ſaline particles with which theſe aſhes abound, have a moſt happy effect in promoting vegetation; and if uſed with diſcretion, the increaſe procured by them is truly wonderful.

" I ſuppoſe few of your readers will be at a loſs to know what peat or turf is, moſt people having ſeen a kind of it burnt as fuel.

" The ordinary peat is dug from wet bogs and moraſſes; but that which is of much ſuperior quality and virtue in its aſhes, is dug from moory wettiſh lands, which will bear cattle: as to the peat that is pared from the ſurface of heaths and commons, for firing for the poor cottagers, the aſhes of it are of very little value, when compared with thoſe above-mentioned.

" Peat is found in moſt low grounds that lie betwixt hills, eſpecially if timber has formerly ſtood upon the ſpot. It lies at various depths, being often near the ſurface, and ſometimes ſix, eight, or ten feet deep, having a ſtratum of black moory earth over it, ſuch as is the ſoil of many of our low meadows near the banks of rivers: it ſometimes even lies under a bed of gravel.

" Peat may be burnt for the ſake of procuring its aſhes for manure, all the ſummer ſeaſon: as ſoon as it is dug, ſome of it is mixed in a heap regularly diſpoſed with faggot wood, or other ready burning fuel: after a layer or two of it mixed in this manner, peat alone is piled up to complete the heap. A heap will conſiſt of from one hundred to a thouſand loads.

" After ſetting fire to it at a proper place, before on purpoſe prepared, it is watched in the burning, and the great art is to keep in as much of the ſmoke as poſſible, provided that as much vent is left as will nouriſh and feed the fire.

" Whenever a crack appears, out of which the ſmoke eſcapes, the labourer in that place lays on more peat; and if the fire ſlackens too much within, which may eaſily be known by the heat on the outſide, the workman muſt run a ſtrong pole into the heap in as many places as is neceſſary to ſupply it with a quantity of freſh air. When managed in this manner, the work goes on as it ſhould do. It is to be noticed, that when once the fire is well kindled, the heavieſt rain does it no harm whilſt it is burning.

" Having procured a ſufficient quantity of aſhes, the farmer's next care ſhould be to apply them properly to uſe; and to do this, he muſt be well acquainted with the nature of the manure he is to lay on his land.

" All aſhes are of a hot, fiery, cauſtic nature; they muſt therefore be uſed with caution. With reſpect to peat-aſhes, almoſt the only danger proceeds from laying them on in too great quantities at improper ſeaſons.

" Nothing can be better than peat-aſhes for dreſſing low damp meadows, laying to the quantity of from fifteen to twenty Wincheſter buſhels on an acre: it is beſt to ſow them by hand, as they will then be more regularly ſpread.

" This work ſhould be done in January or February at lateſt, that the aſhes may be waſhed in towards the roots of the graſs by the firſt rains that fall in the ſpring.

" If they were ſpread more forward in the year, and a ſpeedy rain ſhould not ſucceed, being hot in their nature, they would be apt to burn up the graſs, inſtead of doing it any ſervice.

" It is to be remembered, that the damper and ſtiffer the ſoil, the more peat-aſhes ſhould be laid on it; but in graſs lands the quantity ſhould never exceed thirty Wincheſter buſhels, and on light warm lands leſs than half that quantity is fully ſufficient.

" On wheat crops theſe aſhes are of the greateſt ſervice, but they muſt be laid on with the utmoſt diſcretion. Were they to be ſpread in any quantity before the winter, after the ſowing the corn, they would make the wheat too rank, and do more harm than good; was the ſpreading this manure, on the contrary, deferred till the ſpring, the corn could not poſſibly during the winter ſeaſon be benefited by it. After due reflection and repeated experience, my method of management in this caſe is as follows:

" About the beginning of November, before the hard froſts ſet in, I ſow on every acre of my heavy clayey wheat land about eight Wincheſter buſhels of theſe aſhes; on my lighter warmer lands in wheat, I ſow only four buſhels at this ſeaſon.

" The winter-dreſſing is, I imagine, of great ſervice: trifling as the quantity may ſeem, it warms the roots of the plants, brings it moderately forward, preſerves its verdure, and diſpoſes it to get into a growing ſtate the firſt fine weather after Chriſtmas.

" About the latter end of February, or the beginning of March, on the above-mentioned heavy lands in wheat I beſtow another dreſſing of aſhes, by ſowing of them on every acre eight buſhels more; on light lands, in this ſecond dreſſing, I allow only ſix buſhels.

" Theſe aſhes laid on in the ſpring are of the greateſt ſervice, without any probability of danger: if rain falls within a few days after the dreſſing is laid on, it is waſhed in, and has a happy effect on the ſucceeding crop, co-operating with the manure that was laid on in November: if, on the contrary, dry weather for a long continuance ſucceeds, the firſt winter-dreſſing has its full effect, and the quantity laid on in the ſpring is in fact ſo ſmall, that there is very little probability of its burning or hurting the crop.

" This method has ſucceeded very well with me, and I have no reaſon to think it can fail with any one elſe.

" This excellent manure is, I find, of great uſe in the turnep-huſbandry on many accounts, particularly as it much contributes to preſerve the young crop from being devoured by the fly.

" When I ſow my turneps, before I harrow in the ſeed, I have eight buſhels of theſe aſhes ſtrewed by hand on every acre, and when the plants ſhew their firſt leaves above ground, I ſow on every acre four buſhels more: by this management my crops ſeldom fail, when at the ſame time ſome of my neighbours ſow their turnep-land three or four times over.

" But one of the principal advantages derived from theſe aſhes I have not yet mentioned, which is the very great ſervice they are of to every kind of artificial paſture.

" Saintfoin receives great benefit from this manure, and ſo does clover, ray-graſs, and trefoil, provided it is laid on with diſcretion: the proper ſeaſon is about the month of February: the quantity muſt be regulated by the nature of the crop and ſoil; but in my opinion, it ought ſcarcely in any inſtance to exceed thirty Wincheſter buſhels. Clover, with the help of this manure, grows with great luxuriance, inſomuch that I have often had two large crops of hay from the ſame field in a year, and good autumn feed afterwards.

" But the effect of it is moſt ſeen in tares or vetches, and on them it is I beſtow moſt of this manure, as they will bear it, being a very ſucculent plant. I had laſt ſummer a crop of tare-hay that was aſtoniſhing, by the help of theſe aſhes, being above three large loads on an acre. The field contained ſix acres; it was a dryiſh loam, and not very rich. In the beginning of February I cauſed ten buſhels, Wincheſter meaſure, to be ſtrewed on each acre: immediately after the firſt rains had waſhed them in, the ſame quantity was in like manner ſpread, and about the middle of March, I beſtowed on each acre ſix buſhels more for the laſt dreſſing. I am fond of dividing my entire quantities, thinking my crops are thereby leſs expoſed to the danger of being burned, and the manure is beſides more gradual and laſting in its effects.

" My tares came on amazingly, but they run chiefly to haulm, which was what I wiſhed, not having any deſire of ſaving the ſeed, but intending to make the crop in hay: my only fear was, that it would rot on the ground before it was in a proper condition to cut; but this I luckily eſcaped, by the ſoil being tolerably dry, and by the fineneſs of the weather. It was ſo heavy in the ſwarth, that I was obliged to pay an extraordinary price for mowing it.

" I have obſerved above, that I was fearful my tares would have rotted on the ground before they were fit to cut; this was owing entirely to the invigorating quality of the aſhes, which by their ſalts, &c. promoted the growth of the plants even to luxuriance.

" Before I well knew the great fertilizing quality of theſe aſhes, I loſt, by improper management, a fine three acre piece of hog-peaſe. I laid on this field, ſoon after the peaſe came up, threeſcore Wincheſter buſhels of theſe aſhes at one dreſſing: this brought them forward a great pace, but at harveſt I found, to my grief, I had ſcarcely any corn, for I had overdone it in laying on ſo much, and the peaſe were run all to haulm.

" Ever ſince this accident I have declined uſing them as a common dreſſing for my peaſe; and this I have been the more induced to do, as, in ſeveral little experiments I have ſince made, I have found it extremely difficult to apportion the ſeveral quantities which ought to be laid on various ſoils when ſown with peaſe; for the quantity that has one year ſucceeded very well with me, has the next, owing to the difference of ſeaſons, on the ſame ſoil, in another part of the ſame field, totally diſappointed me; ſo that, for peaſe, I eſteem it a very critical manure, therefore very cautiouſly to be uſed.

" The effects of this manure will be viſible at leaſt three years, and it does not, like ſome others, leave the land in an impoveriſhed ſtate, when its virtues are exhauſted and ſpent.

" Peat-aſhes are not ſo certain a manure for barley and oats as for the winter-corn: for as theſe are quick growers, and occupy the land but a few months, this warm manure is often apt to puſh them forward too faſt, and make them run too much to coarſe ſtraw, yielding only a lean immature grain. Oats, however, are not ſo apt to be damaged by it as barley.

" To get a good crop of barley, I often ſow it after turneps, which have two light dreſſings of aſhes, in the manner above deſcribed.

" When the turneps are fed off, or drawn, I give the field, if the ſeaſon permits, a good ploughing: if they were fed off, the land will want no more aſhes; but if they were drawn, and either carried into another ground to feed ſheep, or given to my ſtall-fed oxen, I ſtrew on each acre, after this ploughing, five Wincheſter buſhels of aſhes, leaving them to be waſhed in by the firſt rain. In this manner I let the land lie till I give it the ſecond and laſt ploughing before it is ſown. The manure has by this management the deſired effect, and the barley generally produces full and heavy ears.

" When I ſow my barley after turneps, I give the land only two ploughings, becauſe the ſoil was before much looſened by the hoeings beſtowed on the turneps; but in other caſes I am fond of allowing three, and ſometimes four ploughings to my lands deſtined for barley; and I generally find it anſwer very well; for many years experience has convinced me, that upon a fine tilth barley always thrives beſt, and yields moſt: in fact, the crop is almoſt always governed by the condition of the land, and a well tilled ſoil is leſs expoſed to danger in an untoward ſeaſon.

" Peat-aſhes approach, in their effects on the ſeveral crops on which they are laid, to coal-ſoot; but two-thirds of the quantity that is uſed of ſoot, will be ſufficient of the aſhes, as they are in a much ſtronger degree, impregnated with a vegetative power; and they are, beſides, in moſt places eaſier procured in quantities, and at a cheaper rate.

" It may poſſibly be objected, that this manure requires great nicety in the application: I allow it does; yet every intelligent farmer, who knows the nature and qualities of the ſoils of his ſeveral fields, will ſoon be able, with great

great preciſion, to judge how much he ought to lay on each acre: his chief care at firſt ſhould be not to overdo it; for therein conſiſts the principal danger; though, after all, theſe aſhes will, at the worſt, unleſs laid on in very great exceſs indeed, only occaſion the inexperienced farmer the perhaps partial loſs of a ſingle crop; for the ſucceeding year they will, in all probability, have a very ſalutary effect on the land, and ſometimes even repay the preceding loſs.

"When the error is in the exceſs, it is very eaſy for a farmer to avoid falling into it; for, independent of every other conſideration, the ſole view of leſſening his expences will, it is imagined, ſufficiently induce him to be attentive to this particular.

"When peat is burnt for the ſake of its aſhes in ſummer time, it is neceſſary that ſome care ſhould be taken to defend them from the too powerful influence of the ſun, air, dews, rains, &c. or great part of their virtue would be exhaled and exhauſted. If the quantity of aſhes procured is not very great, they may be eaſily put under cover in a barn, cart-lodge or hovel; but large quantities muſt neceſſarily, to avoid expence, be kept abroad; and when this is the caſe, they ſhould be ordered as follows.

"A dry ſpot of ground muſt be choſen; and on this the aſhes are to be laid in a large heap, as near as poſſible in the form of a cone ſtanding on its baſe, the top as ſharp pointed as poſſible: when this is done, let the whole be covered thinly over with a coat of ſoil, to defend the heap from the weather: the circumjacent earth, provided it is not too light and crumbly, will always ſerve for this purpoſe.

"When thus guarded, the heap may very ſafely be left till January or February, when it is in general the ſeaſon for ſpreading it: but, before it is uſed, it is always beſt to ſift the aſhes, that the cinders, ſtones, and half burnt turf, may be ſeparated from them.

"This may, perchance, by many be eſteemed an unneceſſary trouble; but experience, which is the beſt guide, has convinced me, that by this means I can better aſcertain the quantity that ought to be ſown on the ſeveral ſorts of land; for the ſmall powdered aſhes, being equal in quality, are of courſe equal in its effect: whereas, when there has been any other mixture with them, the effect has often been greater or leſs than I could have wiſhed. Thus, when I mention the number of buſhels I ſtrew on an acre, it is always to be underſtood of ſifted aſhes: ſhould any farmer be inclined to try them rough as they are firſt produced after burning, the quantity to be allowed for an acre muſt be more in proportion to the mixture of other matter that is in them.

"Theſe peat-aſhes are almoſt, as I have already obſerved, a general manure ſuited to every ſoil. On cold clay they warm the too compact particles, diſpoſe it to ferment, crumble, and of courſe fertilize, and, in fine not only aſſiſt it in diſcloſing and diſpenſing its great vegetative powers, but alſo bring to its aid a conſiderable proportion of ready prepared aliment for plants.

"On light lands theſe aſhes have a different effect: here the pores are too large to be affected, or farther ſeparated by the ſalts or ſulphur contained in them; but, being cloſely attached to the ſurfaces of the large particles, of which this earth is generally compoſed, this manure diſpoſes them, by means of its ſalts, to attract the moiſture contained in the air: by this operation, the plants which grow on theſe porous ſoils, are prevented from being ſcorched up and burnt; and if they want, which they generally do, more nouriſhment than the land is of itſelf capable of affording, this is readily and abundantly ſupplied by this uſeful manure.

"In large farms it is very uſual to ſee all the home-fields rich and well-mended by the yard-dung, &c. whereas the more diſtant lands are generally poor, impoveriſhed, and out of heart, for want of proper manure being applied in time.

"Whilſt the farmers depend almoſt entirely on their yard-dung, this cannot fail being the caſe; for dung is of very heavy carriage: they are willing, therefore, to drop it as near home as poſſible, being in this way able to do a great deal more work in the ſame ſpace of time: but would they once try the virtue of peat-aſhes, all their lands might be alike improved, though at a very conſiderable diſtance from the home-ſtall; for ſo few of them are required, and they are ſo light of carriage, that a ſingle tumbril will hold as many as ought, in moſt caſes, to be laid on two acres of land; by which means, when theſe aſhes are uſed as a dreſſing for the diſtant fields, it coſts the farmer leſs in carriage than does that of the ſtable-dung for his home-fields." *Muſeum Ruſticum, vol.* I. *page* 222.

PENNY-*earth*, a term uſed by the farmers for a hard, loamy, or ſandy earth, with a very large quantity of ſea ſhells intermixed in it; ſome of which being round and flat, and in ſome meaſure reſembling pieces of money, have occaſioned the earth's being called by this name. It is an earth not eaſily dug, but is uſually undermined with pickaxes, and then falls in large lumps; which, with the froſts, break to pieces, and leave the ſhells looſe. It is prepared by breaking and mixing well with water, and then makes very deſirable floors. The Jerſey combers comb-pots, are alſo made of it, and the ſides and roofs of ovens are plaiſtered with it; and, being rightly managed, it combines into a floor almoſt as ſtrong as plaiſter of Paris. *Moreton's Northamptonſhire.*

PERRY, the name of a very pleaſant and wholeſome liquor extracted from pears, in the ſame manner as cyder is from apples. *See the article* CYDER.

The beſt pears for perry, or at leaſt the ſorts which have been hitherto deemed the fitteſt for making this liquor, are ſo exceſſively tart and harſh, that no mortal can think of eating them as fruit: for even hungry ſwine will not eat them, nay, hardly ſo much as ſmell to them. Of theſe the Boſbury pear, the Bareland pear, and the horſe pear, are the moſt eſteemed for perry in Worceſterſhire, and the ſquaſh pear, as it is called, in Glouceſterſhire; in both which counties, as well as in ſome of the adjacent parts, they are planted in the hedge-rows and moſt common fields.

There is this advantage attending pear trees, that they will thrive on land where apples will not ſo much as live, and that ſome of them grow to ſuch a ſize, that a ſingle pear tree, particularly of the Boſbury and the ſquaſh kind, has frequently been known to yield, in one ſeaſon, from one to four hogſheads of perry. The Boſbury pear is thought to yield the moſt laſting and moſt vinous liquor. The John pear, the Harpary pear, the Drake pear, the Mary pear, the Lullum pear, and ſeveral others of the harſheſt kinds, are eſteemed the beſt for perry, but the redder or more tawney they are, the more they are preferred. Pears, as well as apples, ſhould be full ripe before they are ground.

Dr. Beale,

Dr. Beale, in his general advertiſements concerning cyder, ſubjoined to Mr. Evelyn's Pomona, diſapproves of Palladius's ſaying, that perry will keep during the winter, but that it turns ſour as ſoon as the weather begins to be warm; and gives, as his reaſons for being of a contrary opinion, that he had himſelf taſted at the end of ſummer, a very briſk, lively, and vinous liquor, made of horſe pears; that he had often tried the juice of the Boſbury pear, and found it both pleaſanter and richer the ſecond year, and ſtill more ſo the third, though kept only in common hogſheads, and in but indifferent cellars, without being bottled; and that a very honeſt, worthy, and ingenious gentleman in his neighbourhood aſſured him, as of his own experience, that it will keep a great while, and grow much the ſtronger for keeping, if put into a good cellar, and managed with due care. He imputes Palladius's error to his poſſibly ſpeaking of common eatable pears, and to the perry's having been made in a very hot country: but he would have aſcribed it to a more real cauſe, perhaps, had he pointed out the want of a thorough regular fermentation, to which it appears plainly that the ancients were entire ſtrangers; for all their vinous liquors were medicated by boiling, before they were laid up in order to be kept. *See the article* CYDER.

PHEASANT, a bird ſo nearly allied to our common poultry, that it would naturally appear a very eaſy thing to breed them up from young; but the proper food of them is not ſufficiently enquired into. Though they eat corn when full grown and in health, yet they have recourſe in their young ſtate, and when ſick, to another ſort of food, preying on ſeveral inſects, and that in a very voracious manner.

The young pheaſants and partridges prey upon ants; and they will never ſucceed with us, if they have not a proper quantity of ants to have recourſe to, as ſoon as they leave their rooſt in a morning. When muſty corn, or want of due care in cleaning their houſes, has made them ſick, a repaſt of ants will often recover them. When that fails, they may be offered millepedes or earwigs, or both together, which will always do much better than either ſingly. To this medicine muſt be added a proper care that their common food of corn be very ſweet, their habitation kept nicely clean, and their water ſhifted twice a day. They muſt not be let out of the houſe in a morning till the dew is off the ground; and after ſun-ſet they muſt be immediately taken in again: in the heat of the day they muſt be allowed to baſk in the ſun in a dry ſandy place. With theſe regulations the birds of this kind will ſucceed much better than they uſually do. The pheaſant is a bird of a ſullen diſpoſition, and, when the coupling time is over, there are ſeldom found more than one in a place. *Philoſ. Tranſ.* N° 23.

PIGEON, the name of a well known bird, and of which here are two kinds, the wild and the tame; the latter differ from the former only in bigneſs and familiarity; the wild uſually perch upon trees, being ſeldom ſeen on the ground. Pigeons are of various ſorts, ſuch as carriers, powters, runts, turbets, &c.

There are two ſeaſons when you may eaſily procure a ſufficient ſtock of pigeons, viz. May and Auguſt: for at theſe ſeaſons there are a great number of young pigeons, which may then be purchaſed very reaſonably.

PIGEON HOUSE, a houſe erected full of holes within for the keeping, breeding, &c. of pigeons, otherwiſe called a dove-cote.

Any lord of a manor may build a pigeon-houſe on his land, but a tenant cannot do it without the lord's licence. When perſons ſhoot at or kill pigeons within a certain diſtance of the pigeon-houſe, they are liable to pay a forfeiture.

In order to erect a pigeon-houſe to advantage, it will be neceſſary, in the firſt place, to pitch upon a convenient ſituation, of which none is more proper than the middle of a ſpacious court-yard, becauſe pigeons are naturally of a timorous diſpoſition, and the leaſt noiſe they hear frightens them. With regard to the ſize of the pigeon-houſe, it muſt depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too little; and as to its form, the round ſhould be preferred to the ſquare ones; becauſe rats cannot ſo eaſily come at them in the former as in the latter. It is alſo much more commodious; becauſe you may, by means of a ladder turning upon an axis, eaſily viſit all the neſts in the houſe, without the leaſt difficulty; which cannot ſo eaſily be done in a ſquare-houſe.

In order to hinder rats from climbing up the outſide of the pigeon-houſe, the wall ſhould be covered with tin plates to a certain height, about a foot and a half will be ſufficient; but they ſhould project out three or four inches at the top, to prevent their clambering any higher.

The pigeon-houſe ſhould be placed at no great diſtance from water, that the pigeons may carry it to their young ones; and their carrying it in their bills will warm it, and render it more wholeſome in cold weather.

The boards that cover the pigeon-houſe ſhould be well joined together, ſo that no rain may penetrate through it. And the whole building ſhould be covered with hard plaſter, and white-waſhed within and without, white being the moſt pleaſing colour to pigeons. There muſt be no window, or other opening, in the pigeon-houſe to the eaſtward; theſe ſhould always face the ſouth, for pigeons are very fond of the ſun, eſpecially in winter.

The neſts or covers in a pigeon-houſe, ſhould conſiſt of ſquare holes made in the walls of a ſize ſufficient to admit the cock and hen to ſtand in them. The firſt range of theſe neſts ſhould not be leſs than four feet from the ground, that the wall underneath being ſmooth, the rats may not be able to reach them. Theſe neſts ſhould be placed in quincunx order, and not directly over one another. Nor muſt they be continued any higher than within three feet of the top of the wall: and the upper row ſhould be covered with a board projecting a conſiderable diſtance from the wall, for fear the rats ſhould find means to climb the outſide of the houſe.

M. Duhamal thinks that pigeons neither feed upon the green corn, nor have bills ſtrong enough to ſearch for its ſeeds in the earth; but only pick up the grains that are not covered, which would infallibly become the prey of other animals, or be dried up by the ſun. "From the time of the ſprouting of the corn, ſays he, pigeons live chiefly upon the ſeeds of wild uncultivated plants, and therefore leſſen conſiderably the quantity of weeds that would otherwiſe ſpring up; as will appear from a juſt eſtimate of the quantity of grain neceſſary to feed all the pigeons of a well-ſtocked dove houſe." But Mr. Worlidge and Mr. Liſle alledge facts in ſupport of the contrary opinion. The latter relates, that a farmer in his neighbourhood aſſured him he had known an acre ſowed with peas, and rain coming on ſo that they could not be harrowed in, every pea was fetched away in half a day's time by pigeons: and the former

former ſays, "It is to be obſerved, that where the flight of pigeons falls, there they fill themſelves and away, and return again where they firſt roſe, and ſo proceed over a whole piece of ground, if they like it. Although you cannot perceive any grain above the ground, they know how to find it. I have ſeen them lie ſo much upon a piece of about two or three acres ſown with peas, that they devoured at leaſt three parts in four of the ſeed, which, I am ſure, could not be all above the ſurface of the ground. That their ſmelling is their principal director, I have obſerved; having ſown a ſmall plat of peas in my garden, near a pigeon-houſe, and covered them ſo well that not a pea appeared above ground. In a few days, a parcel of pigeons were hard at work in diſcovering this hidden treaſure; and in a few days more I had not above two or three peas left out of about two quarts that were planted; for what they could not find before, they found when the buds appeared, notwithſtanding they were hoed in, and well covered. Their ſmelling alone directed them, as I ſuppoſed, becauſe they followed the ranges exactly. The injury they do at harveſt on the peas, vetches, &c. is ſuch that we may rank them among the greateſt enemies the poor huſbandman meets withal; and the greater, becauſe he may not erect a pigeon-houſe, whereby to have a ſhare of his own ſpoils; none but the rich being allowed this privilege, and ſo ſevere a law being alſo made to protect theſe winged thieves, that a man cannot encounter them, even in defence of his own property. You have therefore no remedy againſt them, but to affright them away by noiſes, or ſuch like. You may, indeed, ſhoot at them; but you muſt not kill them; or you may, if you can, take them in a net, cut off their tails, and let them go; by which means you will impound them: for when they are in their houſes, they cannot bolt or fly out of the tops of them, but by the ſtrength of their tails, after the thus weakening of which, they remain priſoners at home."

Mr. Worlidge's impounding the pigeons reminds me of a humorous ſtory of a gentleman who, upon a neighbouring farmer's complaining to him, that his pigeons were a great nuiſance to his land, and did ſad miſchief to his corn, replied jokingly, Pound them, if you catch them treſpaſſing. The farmer, improving the hint, ſteeped a parcel of peas in an infuſion of coculus indicus, or ſome other intoxicating drug, and ſtrewed them upon his grounds. The pigeons ſwallowed them, and ſoon remained motionleſs on the field: upon which the farmer threw a net over them, incloſed them in it, and carried them to an empty barn, from whence he ſent the gentleman word that he had followed his directions with regard to the pounding of his pigeons, and deſired him to come and releaſe them.

PIGGIN, a little pail or tub, with an erect handle.

PIKE, a name given in ſome counties to what is generally called a fork, uſed for carrying ſtraw, &c. from the barn, cocking of barley, &c.

PINE, the name of a foreſt tree, of which there are various ſpecies, but two only that deſerve cultivating; namely, the Scotch-pine, and the white pine, commonly called in England lord Weymouth's, or New England pine.

The Scotch-pine, ſo called from its growing naturally on the mountains of Scotland, is the tree that affords the red or yellow deal, which is the moſt durable of any of the kinds yet known. The leaves of this tree are pretty broad and ſhort, of a greyiſh colour, growing two out of each ſheath; the cones are ſmall, pyramidal, and end in narrow points; they are of a light colour, and the ſeeds are ſmall.

This ſort grows well upon almoſt every ſoil; I have planted numbers of the trees upon peat bogs, where they have made great progreſs. I have alſo planted them in clay, where they have ſucceeded far beyond expectation; and upon ſand, gravel, and chalk, they likewiſe thrive as well; but as they do not grow near ſo faſt upon gravel and ſand, as upon moiſt ground, ſo the wood is much preferable; for thoſe trees which have been cut down upon moiſt ſoils, where they have made the greateſt progreſs, when they have been ſawn out into boards, have not been valuable, the wood has been white, and of a looſe texture; whereas thoſe which have grown upon dry gravelly ground, have proved nearly equal to the beſt foreign deals; and I doubt not but thoſe plantations, which of late years have been made of theſe trees, will, in the next age, not only turn greatly to the advantage of their poſſeſſors, but alſo become a national benefit.

The white pine is one of the talleſt trees of all the ſpecies, often growing a hundred feet high, as I have been credibly informed. The bark of this tree is very ſmooth and delicate, eſpecially when young; the leaves are long and ſlender, five growing out of each ſheath; the branches are pretty cloſely garniſhed with them, ſo make a fine appearance; the cones are long, ſlender, and very looſe, opening with the firſt warmth of the ſpring: ſo that if they are not gathered in winter, the ſcales open and let out the ſeeds. The wood of this ſort is eſteemed for making of maſts for ſhips; it is in England called lord Weymouth's, or New England pine, as hath been already obſerved. As the wood of this tree was generally thought of great ſervice to the navy, there was a law made in the ninth year of queen Anne, for the preſervation of the trees, and to encourage their growth in America: and it is within forty years paſt theſe trees began to be propagated in England in any plenty, though there were ſome large trees of this ſort growing in two or three places long before, particularly at lord Weymouth's, at Longleet, Sir Wyndham Knatchbull's in Kent; and it hath been chiefly from the ſeeds of the latter that the much greater number of theſe trees now in England have been raiſed; for although there has annually been ſome of the ſeeds brought from America, yet thoſe have been few in compariſon to the produce of the trees in Kent: many of the trees, which have been raiſed from the ſeeds of thoſe trees, now produce plenty of the ſeeds, particularly thoſe in the gardens of the late duke of Argyle at Whitton, which annually produce large quantities of cones, which his grace, when living, moſt generouſly diſtributed to all the curious.

All the ſorts of pines are propagated by ſeeds, which are produced in hard woody cones; the way to get the ſeeds out of theſe cones, which are cloſe, is to lay them before a gentle fire, which will cauſe the cells to open, and then the ſeeds may be eaſily taken out. If the cones are kept entire, the ſeeds will remain good ſome years, ſo that the ſureſt way to preſerve them, is to let them remain in the cones, until the time for ſowing the ſeeds: if the cones are kept in a warm place in ſummer, they will open, and emit the ſeeds; but if they are not expoſed too much to heat, many of the ſorts will remain entire ſome years, eſpecially thoſe which are cloſe and compact; and the ſeeds, which have been taken out of cones of ſeven years old,

old, have grown very well, ſo that theſe may be tranſported to any diſtance, provided the cones are well ripened, and properly put up.

The beſt time for ſowing the ſeeds of pines, is about the end of March; when the ſeeds are ſown, the place ſhould be covered with nets to keep off birds, otherwiſe, when the plants begin to appear with the huſk of the ſeed on their tops, the birds will pick off the heads of the plants and deſtroy them.

Where the quantity of ſeeds to be ſown is not great, it will be a good way to ſow them either in boxes or pots filled with light loamy earth, which may be removed from one ſituation to another, according to the ſeaſon of the year; but if there is a large quantity of the ſeeds, ſo as to require a good ſpace to receive them, they ſhould be ſown on an eaſt or north-eaſt border, where they may be ſcreened from the ſun, whoſe heat is very injurious to theſe plants at their firſt appearance above ground. Thoſe ſeeds, which are ſown in pots or boxes, ſhould alſo be placed in a ſhady ſituation, but not under trees; and if they are ſcreened from the ſun with mats, at the time when the plants firſt come up, it will be a good method to preſerve them.

When the plants appear, they muſt be conſtantly kept clean from weeds, and, in very dry ſeaſons, if they are now and then gently refreſhed with water, it will forward their growth; but this muſt be done with great care and caution, for if they are haſtily watered, it will waſh the tender plants out of the ground, or lay them down flat, which often rots their ſhanks; and when this is too often repeated, it will have the ſame effect; ſo that unleſs it is judiciouſly performed, it will be the beſt way to give them none, but only ſcreen them from the ſun.

If the plants come up too cloſe, it will be a good method to thin them gently about the beginning of July. The plants, which are drawn up, may then be planted on other beds, which ſhould be prepared ready to receive them, for they ſhould be immediately planted as they are drawn up, becauſe their tender roots are ſoon dried and ſpoiled at this ſeaſon of the year. This work ſhould be done, if poſſible, in cloudy or rainy weather, and then the plants will draw out with better roots, and will ſoon put out new fibres again; but if the weather ſhould prove clear and dry, the plants ſhould be ſhaded every day from the ſun with mats, and now and then gently refreſhed with water. In drawing up of the plants, there ſhould be great care taken not to diſturb the roots of the plants left remaining in the ſeed-beds, &c. ſo that if the ground be hard, the beds ſhould be well watered ſome time before the plants are thinned, to ſoften and looſen the earth; and if, after the plants are drawn out, the beds are again gently watered to ſettle the earth to the roots of the remaining plants, it will be of great ſervice to them; but it muſt be done with great care, ſo as not to waſh out their roots, or lay down the plants. The diſtance, which ſhould be allowed theſe plants, is four or five inches row from row, and three inches in the rows.

In theſe beds the plants may remain till the ſpring twelve-months after, by which time they will be fit to tranſplant where they are to remain for good; for the younger plants are, when planted out, the better they will ſucceed; for although ſome ſorts will bear tranſplanting at a much greater age, yet young plants planted at the ſame time will in a few years overtake the large ones, and ſoon outſtrip them in their growth; and there is an advantage in planting young, by ſaving the expence of ſtaking, and much watering, which large plants require. I have ſeveral times ſeen plantations of ſeveral ſorts of pines, which were made of plants ſix or ſeven feet high, and at the ſame time others of one foot high planted between them, which in ten years were better trees than the old ones, and much more vigorous in their growth; but if the ground, where they are deſigned to remain, cannot be prepared by the time before mentioned, the plants ſhould be planted out of the beds into a nurſery, where they may remain two years, but not longer; for it will be very hazardous in removing theſe trees at a greater age.

The beſt ſeaſon to tranſplant theſe pines, is about the latter end of March, or the beginning of April, juſt before they begin to ſhoot; for although the Scotch pine, and ſome of the moſt hardy ſorts, may be tranſplanted in winter, eſpecially when they are growing in ſtrong land, where they may be taken up with balls of earth to their roots, yet this is what I would not adviſe for common practice, having frequently ſeen it attended with bad conſequences; but thoſe which are removed in the ſpring rarely fail.

Where theſe trees are planted in expoſed ſituations, they ſhould be put pretty cloſe together, that they may ſhelter each other, and, when they have grown a few years, part of the plants may be cut down to give room for the others to grow; but this muſt be gradually performed, leſt by too much opening the plantation at once, the air ſhould be let in among the remaining trees with too great violence, which will ſtop their growth.

Wherever large plantations are deſigned to be made, the beſt method will be to raiſe the plants either upon a part of the ſame land, or as near to the place as poſſible, and alſo upon the ſame ſort of ſoil; a ſmall piece of ground will be ſufficient to raiſe plants enough for many acres; but, as the plants require ſome care in their firſt raiſing, if the neighbouring cottagers, who have many of them ſmall incloſures adjoining to their cottages; or, where this is wanting, a ſmall incloſure ſhould be made them for the purpoſe of raiſing the plants, and they be furniſhed with the ſeeds and directions for ſowing them, and managing the young plants, till they are fit for tranſplanting, the women and children may be uſefully employed in this work, and the proprietors of land agreeing with them to take their plants, when raiſed, at a certain price, it would be a great benefit to the poor, and hereby they would be engaged to have a regard for the plantations when made, and prevent their being deſtroyed.

The Scotch pines, as was before obſerved, being the hardieſt of all the kinds, and the wood of it the moſt uſeful, is the ſort which beſt deſerves care. This will thrive upon the moſt barren ſands, where ſcarce any thing elſe except heath and furze will grow; ſo that there are many thouſand acres of ſuch land lying convenient for water carriage, which at preſent is of little benefit to any body, that might, by plantations of theſe trees, become good eſtates to their proprietors, and alſo a national benefit; and as the legiſlators have taken this into their conſideration, and already paſſed ſome laws for the encouraging theſe plantations, as alſo for their preſervation and ſecurity: ſo it may be hoped that this will be undertaken by the gentlemen who are poſſeſſed of ſuch land in all the different parts of the kingdom, with proper ſpirit; for although

although they may not expect to receive much profit from theſe plantations in their own time, yet their ſucceſſors may with large intereſt, and the pleaſure which theſe growing trees will afford them, by beautifying the preſent dreary parts of the country, will in ſome meaſure recompenſe them for their trouble and expence, and by creating employment for the poor, leſſen thoſe rates which are now, in many parts of England, ſcarce to be borne.

The expence of making theſe plantations is what moſt people are afraid of, ſo would not engage in it; but the greateſt of the expence is that of fencing them from the cattle, &c. for the other is trifling, as there will be no neceſſity for preparing the ground to receive the plants, and the charge of planting an acre of land with theſe plants, will not be more than thirty ſhillings where labour is dear, excluſive of the plants, which may be valued at forty ſhillings more. I have planted many acres of land with theſe trees, which was covered with heath and furze, and have only dug holes between to put in the plants, and afterward laid the heath or furze, which was cut upon the ſurface of the ground about their rooots, to prevent the ground drying, and few of the plants have failed. Theſe plants were moſt of them four years old from ſeed, nor was there any care taken to clean the ground afterward, but the whole left to ſhift, and in five or ſix years the pines have grown ſo well, as to over-power the heath and furze, and deſtroy it.

The diſtance which I have generally planted theſe plants in all large open ſituations, was about four feet, but always irregular, avoiding planting in rows as much as poſſible; and in the planting, the great care is not to take up the plants faſter than they can be planted, ſo that ſome men have been employed in digging up the plants, while others were planting. Thoſe who take up the plants, muſt be looked after to ſee they do not tear off their roots, or wound their bark; and as faſt as they are taken up, their roots ſhould be covered to prevent their drying, and put into their new quarters as ſoon as poſſible. In planting them, care ſhould be had to make the holes large enough for their roots, as alſo to looſen and break the clods of earth, and put the fineſt immmediately about their roots, then to ſettle the earth gently with the foot to the roots of the plant. If theſe things are duly obſerved, and a proper ſeaſon choſen for performing it, there will be very little hazard of their ſucceeding; but I have ſeen ſome plantations made with plants, which were brought from a great diſtance, and had been ſo cloſely packed up, as to cauſe a heat, whereby moſt of the plants within had their leaves changed yellow, and few of them have grown, which has diſcouraged others from planting, not knowing the true cauſe of their failure.

After the plantations are made, the only care they require for five or ſix years, will be to ſecure the plants from cattle, hares, and rabbits; for if theſe are admitted to them, they will make great deſtruction in a ſhort time; for if the branches are gnawed by hares or rabbits, it will greatly retard the growth of the plants, if not deſtroy them.

In about five or ſix years after planting, the branches of the young trees will have met, and begin to interfere with each other, therefore they will require a little pruning; but this muſt be done with great caution. The lower tier of branches only ſhould be cut off: this ſhould be performed in September, at which time there will be no danger of the wounds bleeding too much, and the turpentine will harden over the wounds as the ſeaſon grows cold, ſo will prevent the wet from penetrating of them. Theſe branches ſhould be cut off cloſe to the ſtem of the plants, and care ſhould be taken in the doing of this, not to break any of the remaining branches of the young trees. This work ſhould be repeated every other year, at each time taking off only the lower tier of branches; for if the plants are much trimmed, it will greatly retard their growth, as it does in general that of all trees, but as theſe trees never put out any new ſhoots where they are pruned, ſo they ſuffer more from amputation than thoſe which do.

In about twelve or fourteen years theſe will require no more pruning, for their upper branches will kill thoſe below where they have not air; but ſoon after this, if the plants have made good progreſs, it may be neceſſary to thin them; but this ſhould be gradually performed, beginning in the middle of the plantation firſt, leaving the outſide cloſe to ſcreen thoſe within from the cold, ſo by degrees coming to them at laſt, whereby thoſe, which were firſt thinned, will have had time to get ſtrength, ſo will not be in danger of ſuffering from the admiſſion of cold air. When theſe plantations are thinned, the trees ſhould not be dug up; but their ſtems cut off cloſe to the ground, for their roots never ſhoot again, but decay in the earth, ſo there can no harm ariſe by leaving them, and hereby the roots of the remaining plants are not injured. The trees which are now cut, will be fit for many purpoſes; thoſe which are ſtrait, will make good putlocks for the bricklayers, and ſerve for ſcaffolding poles, ſo that there may be as much made by the ſale of theſe, as will defray the whole expence of the planting, and probably intereſt for the money into the bargain.

As the upright growth of theſe trees renders their wood the more valuable, they ſhould be left pretty cloſe together, whereby they will draw each other up, and grow very tall. I have ſeen ſome of theſe trees growing, whoſe naked ſtems have been more than ſeventy feet high, and as ſtrait as a walking cane, and from one of theſe trees there was as many boards ſawed, as laid the floor of a room near twenty feet ſquare. If theſe trees are left eight feet aſunder each way, it will be ſufficient room for their growth; therefore, if at the firſt thinning a fourth part of the trees are taken away, the others may ſtand twelve or fourteen years longer, by which time they will be of a ſize for making ladders, and ſtandards for ſcaffolding, and many other purpoſes; ſo that from this ſale, as much may be made, as to not only pay the remaining part of the expence of planting, if any ſhould be wanting in the firſt, but rent for the land with intereſt, and the ſtanding trees for fortunes of younger children. This may be demonſtrated by figures, and there has been ſeveral examples of late years, where the profits have greatly exceeded what is here mentioned. *Miller's Gard. Dict.*

Pitch, tar, reſin, and turpentine, are all made from theſe trees by a very familiar proceſs. In the ſpring time, when the ſap is moſt free in running, they pare off the bark of the pine-tree, to make the ſap run down into a hole which they cut at the bottom to receive it: in the way, as it runs down, it leaves a white matter like cream, but a little thicker: this is very different from all the kinds of reſin and turpentine in uſe, and it is generally ſold to be uſed in the making of flambeaux, inſtead of

white bees wax. The matter that is received in the hole at the bottom, is taken up with ladles, and put in a large baſket; a great part of this immediately runs through, and this is the common turpentine. This is received into ſtone or earthen pots, and is ready for ſale. The thicker matter, which remains in the baſket, they put into a common alembic, adding a large quantity of water; they diſtil this as long as any oil is ſeen ſwimming upon the water; this oil they ſeparate from the ſurface in large quantities, and this is the common oil or ſpirit of turpentine; the remaining matter, at the bottom of the ſtill, is common yellow reſin. When they have thus obtained all that they can from the ſap of the tree, they cut it down, and, hewing the wood into billets, they fill a pit dug in the earth with theſe billets, and, ſetting them on fire, there runs from them, while they are burning, a black thick matter; this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil: if this hole be made too large, it ſets the whole quantity of the tar on fire; but, if ſmall enough, it runs quietly out.

The tar, being thus made, is put up in barrels, and, if it be to be made into pitch, they put it into large boiling veſſels, without adding any thing to it: it is then ſuffered to boil a while, and, being then let out, is found, when cold, to be what we call pitch. *Philſ. Tranſ.* Numb. 243.

PIP, *or* PEP, a diſeaſe among poultry, conſiſting of a white thin ſkin, or film, which growing under the tip of the tongue, hinders their feeding. It uſually ariſes from their drinking puddle-water, or eating filthy meat; and is cured by pulling off the film with the fingers, and rubbing the tongue with ſalt.

PLEURISY, and inflammation of the lungs, &c. are diſorders in horſes, though they have ſcarce been mentioned by any writer in farriery before Mr. Gibſon; who, by frequently examining the carcaſes of dead horſes, has found them ſubject to the different kinds of inflammations here deſcribed.

He has often diſcovered matter on the pleura (or membrane which lines the cheſt internally) making its way into the cheſt; he has found in ſome horſes the whole ſubſtance of the lungs black, and full of gangrened water; and in others abſceſſes of various ſizes; and, in ſhort, inflammations in every bowel. He has frequently ſeen the blood veſſels ſo over-loaded, that the blood has burſt out of the ſmaller veſſels, and run over their carcaſſes in many places, while the collar-maker was fleaing off their hides, and on cutting open the larger veſſels, the blood has guſhed out as from a fountain, filling all the cavity of the body; an evident proof, that plentiful evacuations had been neglected. In order to diſtinguiſh theſe diſorders from others, we ſhall deſcribe the ſymptoms in Mr. Gibſon's own words.

"A pleuriſy then, which is an inflammation of the pleura, and a peripneumony, which is an inflammation of the lungs, have ſymptoms very much alike; with this difference only, that in a pleuriſy a horſe ſhews great uneaſineſs, and ſhifts about from place to place; the fever, which at firſt is moderate, riſes ſuddenly very high; in the beginning he often ſtrives to lie down, but ſtarts up again immediately, and frequently turns his head towards the affected ſide, which has cauſed many to miſtake a pleuritic diſorder for the gripes, this ſign being common to both, though with this difference:

"In the gripes a horſe frequently lies down, and rolls, and when they are violent, he will alſo have convulſive twitches, his eyes being turned up, and his limbs ſtretched out, as if he was dying; his ears and feet ſometimes occaſionally hot, and ſometimes as cold as ice; he falls into profuſe ſweats, and then into cold damps, ſtrives often to ſtale and dung, but with great pain and difficulty; which ſymptoms generally continue, till he has ſome relief: but in a pleuriſy, a horſe's ears and feet are always burning-hot, his mouth parched and dry, his pulſe hard and quick; even ſometimes when he is nigh dying, his fever is continued and increaſing; and though in the beginning he makes many motions to lie down, yet afterwards he reins back as far as his collar will permit, and makes not the leaſt offer to change his poſture, but ſtands panting with ſhort ſtops, and a diſpoſition to cough, till he has relief, or drops down.

"In an inflammation of the lungs, ſeveral of the ſymptoms are the ſame, only in the beginning he is leſs active, and never offers to lie down during the whole time of his ſickneſs; his fever is ſtrong, breathing difficult, and attended with a ſhort cough; and whereas in a pleuriſy, a horſe's mouth is generally parched and dry, in an inflammation of the lungs, when a horſe's mouth is open, a roapy ſlime will run out in abundance; he gleets alſo at the noſe a reddiſh or yellowiſh water, which ſticks like glue to the inſide of his noſtrils.

"In a pleuriſy, a horſe heaves and works violently at his flanks, with great reſtleſſneſs, and for the moſt part his belly is tucked up; but in an inflammation of the lungs, he always ſhews fullneſs, and the working of his flanks is regular, except after drinking and ſhifting his poſture: and his ears and feet are for the moſt part cold, and often in damp ſweats.

"The cure of both theſe diſorders is the ſame. In the beginning a ſtrong horſe may loſe three quarts of blood, the next day two quarts more; and if ſymptoms do not abate, the bleedings muſt be repeated, a quart at a time; for it is ſpeedy, large, and quick repeated bleedings that are in theſe caſes chiefly to be depended on. But if a horſe has had any previous weakneſs, or is old, you muſt bleed him in leſs quantities, and oftener. Mr. Gibſon recommends rowels, on each ſide the breaſt, and one on the belly; and a bliſtering ointment to be rubbed all over his briſket upon the foremoſt ribs.

"The diet and medicines ſhould be both cooling, attenuating, relaxing, and diluting; and the horſe ſhould have warm maſhes, and plenty of water or gruel. The following balls may be given thrice a day.

> "Take of ſpermaceti and nitre, of each one ounce; oil of aniſeed thirty drops; honey enough to make a ball.

"A pint of barley-water, in which figs and liquorice-root have been boiled, ſhould be given after each ball; to which the juice of lemons may be added; and if the lungs are greatly oppreſſed with a dry ſhort cough, two or three horns full of the decoction may be given three or four times a day, with four ſpoonfuls of honey and linſeed oil. A ſtrong decoction of the rattle-ſnake root is alſo much recommended in pleuritic diſorders, and may be given to the quantity of two quarts a day, ſweetened with honey. It remarkably attenuates the blood, and diſperſes

perſes the inflammation, and in ſome parts is deemed a ſpecific for this complaint.

"An emollient clyſter ſhould be injected once a day, to which may be added two ounces of nitre, or cream of tartar.

"In two or three days he will probably run at the noſe, and begin to feed; but ſhould he not, and continue hot and ſhort breathed, you muſt bleed him again, and give the following clyſter:

"Take ſenna and marſhmallows, of each two ounces; fennel and bay-berries, each one ounce: boil in five pints of water to two quarts, pour off the clear, and add four ounces of purging ſalts, two or three of ſyrup of buckthorn, and half a pint of linſeed, or any common oil.

"If by theſe means he grows cooler, and his pain moderates, repeat the clyſter the next day, unleſs it worked too much; then intermit a day; and when he comes to eat ſcalded bran and picked hay, leave off the balls, and continue only the decoction, with now and then a clyſter.

"But let it be obſerved, that a horſe ſeldom gets the better of theſe diſorders, unleſs he has relief in a few days; for if the inflammation is not checked in that time, it uſually terminates in a gangrene, or collection of matter, which for want of expectoration, ſoon ſuffocates him.

"But as pleuritic diſorders are apt to leave a taint on the lungs, great care ſhould be taken of the horſe's exerciſe and feeding, which ſhould be light and open for two or three weeks. Thus a quartern of bran ſcalded, with a ſpoonful of honey and flour of brimſtone, may be given every day, with two or three ſmall feeds of oats, ſprinkled with chamber-lye. Inſtead of the bran, for a change, give about a quart of barley ſcalded in a double infuſion of hot water, that it may be ſoftened, and the water given to drink. His exerciſe ſhould be gradual, in an open air and fair weather; and when his ſtrength is recovered, a gentle purge or two ſhould be given; that of rhubarb, when it can be afforded, is beſt, or the purging drink already recommended for this purpoſe.

"There is alſo an external pleuriſy, or inflammation of the muſcles between the ribs, which when not properly treated, proves the foundation of that diſorder, called the cheſt-founder; for if the inflammation is not diſperſed in time, and the viſcid blood and juices ſo attenuated by internal medicines, that a free circulation is obtained; ſuch a ſtiffneſs and inactivity will remain on theſe parts, as will not eaſily be removed, and which is generally known by the name of cheſt-founder.

"The ſigns of this inflammation, or external pleuriſy, are a ſtiffneſs of the body, ſhoulders, and fore-legs; attended ſometimes with a ſhort dry cough, and a ſhrinking when handled in thoſe parts.

"Bleeding, ſoft pectorals, attenuants, and gentle purges are the internal remedies; and externally the parts affected may be bathed with equal parts of ſpirit of ſal armoniac, and ointment of marſhmallows, or oil of chamomile.

Theſe outward inflammations frequently fall into the inſide of the fore leg, and ſometimes near the ſhoulder; forming abſceſſes, which terminate the diſorder.

The membrane which ſeparates the lungs, and more particularly the diaphragm, or midriff, is often alſo inflamed; which is ſcarce to be diſtinguiſhed from the pleuriſy, only in this, that when the midriff is greatly inflamed, the horſe will ſometimes be jaw-ſet, and his mouth ſo much cloſed, that nothing can be got in: but the method of cure is the ſame." *Bartlett's Farriery, page* 51.

PLOUGH, a well known machine for breaking up the ground.

The advantage of digging with the ſpade, or ſuch other inſtrument, very naturally led men to the invention of the plough, a greatly more expeditious way of doing the ſame thing; that is, cutting and breaking the earth into ſmall pieces; but in this the ſpade has the advantage of the common plough, as it goes deeper, and divides the earth more minutely; but the improvement of the common plough into the four-coultered one, ſhews that it is eaſy to make the plough perform this office as much better, as it uſually does it worſe than the ſpade.

The plough deſcribed by Virgil had no coulter; and at this time, the ploughs of Italy and the ſouth of France, have none; and the ploughs in Greece, and in the eaſtern nations in general, are of the ſame kind. Neither is it indeed poſſible to uſe a coulter in ſuch a plough; becauſe the ſhare does not cut the bottom of the furrow horizontally, but obliquely: in going one way it turns off the furrow to the right-hand, but in coming back it turns it off to the left; therefore if it had a coulter, it muſt be on the wrong ſide every other furrow.

It is a great miſtake in thoſe who ſay that Virgil's plough had two earth-boards, for it really had none at all; but the ſhare itſelf always going obliquely, ſerved inſtead of an earth-board; and two ears, which were the corners of a piece of wood lying under the ſhares, did the office of ground-wriſts. This faſhion of the plough continues to this day in thoſe countries; and in Languedoc this ſort of plough performs tolerably well when the ground is fine, and makes a ſhift to break up light land. This is the ſort of land that is common in the Eaſt, and the arable lands about Rome, being never ſuffered to be fallow ſo long as to come to turf: this plough ſucceeds very well in ſuch places, but it would be wholly impoſſible to turn up what in England we call ſtrong land, with it.

The Engliſh ploughs are therefore different from theſe, as the ſoil is different. Our ploughs, where well made, cut off the furrow at the bottom horizontally; and therefore, it being as thick on the land ſide as on the furrow ſide, the ploughs cannot break it off from the whole land at ſuch a thickneſs, being ſix times greater than what the eaſtern ploughs have to break off, and for this purpoſe it muſt have, of neceſſity, a coulter to cut it off: by this means the furrow is turned perfectly whole, and no part of the turf of it is broken; and if it lie long without new turning, the graſs from the edges will ſpread, and form a new turf on the other ſide, which was the bottom of the furrow before the turning; but is now become the ſurface of the earth, and will ſoon become greener with graſs than it was before ploughing.

If whole, ſtrong, turfy furrows are ploughed croſs ways, as is too commonly practiſed, the coulter cannot eaſily cut them; becauſe, being looſe underneath, they do not make a proper reſiſtance or preſſure againſt its edge, but are apt to be drawn on heaps, and turned in all directions, but without cutting.

Some of our ploughs have heavy drags, with long iron tines in them; and though theſe broken pieces of furrows, being now looſer than before, require keener edges to cut

them, theſe tines have no edges at all. Thus the clods of earth are toſſed into heaps again, and the ſurface left bare between them, and great labour and expence is uſed to very little purpoſe: all this is owing to the one coulter.

If the ſoil be ſhallow, it may be broken up with a narrow furrow, which will the ſooner be brought into tilth; but if it be a deep ſoil, the furrows muſt be proportionally enlarged, or elſe a great part of the good mould will be left unmoved, and ſo be loſt. The deeper the land is, the worſe it is broke by one coulter; that is, it is broke into larger furrows, and it requires ſuch repeated labour to conquer this, that, often, the beſt land will ſcarcely pay the tillage.

This gives an opportunity to ſervants to cheat their maſters. They plough ſuch deep land with a ſmall furrow, and ſhallow, to the end, that the turf and furrows may be broken the ſooner, and the ſuperficial part made fine. They pretend the plough will go deeper the next time; but this is never the caſe.

This ſort of land muſt not be ploughed the ſecond time in wet weather; for this will cauſe the weeds to multiply, and the earth will be formed into thick and heavy clods where trodden: and in dry weather, the reſiſtance of the untouched earth below, and the ſlight preſſure of the plough above, will always be reaſons why the plough will enter no deeper the ſecond time than it did the firſt.

Another way to conquer ſtrong turf, is to plough it up firſt with a breaſt plough, very thin; and when the ſwerd is rotten, then it is to be ploughed to the proper depth: but this method is liable to great objections; it is very troubleſome and expenſive, and if the turf be pared off in the winter, or early in ſpring, it is a chance but the rains come on, and ſet it to growing faſter than before: if, on the other hand, it be pared later in the year, though the turf be thoroughly killed by the ſucceeding dry weather, yet the time is loſt, and the farmer loſes the ſowing ſeaſon for wheat, which is the proper corn for ſuch ſtrong land.

Paring PLOUGH, an inſtrument uſed in ſeveral parts of England, for paring off the ſurface of the ground, in order to its being burnt. *See the article* BURN-BAKING.

One of the beſt and ſimpleſt inſtruments of this kind is that which Mr. Bradley gives, with the following deſcription.

Fron A to A, Fig. 1. Plate XXI. is the plough-beam, about ſeven feet long, mortiſed and pinioned into the block B, which is of clean timber, without knots. CC are the ſheaths or ſtandards, made flat on the inſide, to cloſe equally with the paring-plate, and be faſtened to it with a bolt and key on each ſide, as is marked at D.

E is the paring plate of iron laid with ſteel, about four inches wide, and from twelve to eighteen inches long, as the buſineſs may require. This plate muſt be made to cut on the ſides, which are bolted to the ſtandards, as well as at the bottom part.

FF are two iron braces, to keep the ſtandards from giving way. Theſe ſtandards muſt be mortiſed near their outſides, and through the block.

GG are the plough handles, which muſt be fixed ſlopewiſe between the beam and the ſtandards.

The pin-holes in the beam, the uſe of which is to make this plough cut more or leſs deep, by fixing the wheels nearer to or farther from the paring-plate, ſhould not be above two inches aſunder.

Rotheram, or *Patent* PLOUGH, the name of a plough very ſimple in its conſtruction, eaſily worked, and therefore deſerves the huſbandman's particular attention.

Fig. 2. Plate XXI. repreſents the left or land ſide of this plough, of which AB is the beam, CD the ſheath, EBD the main handle, FR, the ſmaller handle, GH the coulter, KI the ſock or ſhare, NP the bridle, S the fly-band, MI, a piece of wood in place of a head. The forms of all theſe different parts, as they appear on this ſide of the plough, are here repreſented, and their ſizes and diſtances may be meaſured by the annexed ſcale of feet and inches.

Fig. 3. repreſents the right-hand ſide of this plough, with all the parts that can be ſeen on that ſide, in which TV is the mould-board, &c.

Fig. 4. ſhews the under part of this plough turned up, in which may be ſeen the ſhape and ſize of the ſhare, and the manner in which it is fixed on the ſheath, mould-board, and ground-reſt, with the angle which they make.

Fig. 5. repreſents the hind-part of the plough, in which are ſeen the two handles EF, with the hinder-part of the mould-board VT, and a piece of wood in the place of the head LM, in their proper ſhapes and ſizes by the ſcale.

Fig. 6. repreſents an upper view of this plough, as it appears while it works, with the bridle NP extended, the mould-board TV, fixed in its proper poſition, and all the other parts as they appear in this ſituation, in their ſeveral ſhapes and ſizes according to the ſcale.

Fig. 7. is the upper part of the ſock or ſhare.

Fig. 8. ſhews the opening of the ſhare, as it is fixed on the end of the ſheath and mould-board.

Fig. 9. is a perſpective view of the bridle.

The whole of this plough ſhould be made of aſh or elm; the irons ſhould be ſteeled and well tempered; and that part of the plough which is under ground in tilling, ſhould be covered with plates of iron.

The difference betwixt this and the common ploughs, ſeems to conſiſt in the bridle at the end of the beam, by which the ploughman can give the plough more or leſs land by the notches at N in Fig. 4, and 6. or make it cut deeper or ſhallower by the holes at P in Fig. 2, and 3. in the coulter and ſhare, which are made and ſet ſo as to cut off the new furrow without tearing; and in the mould-board, which is ſo ſhaped at firſt to raiſe a little, and then gradually turn over the new cut furrow with very little reſiſtance. But the greateſt advantage of all is, it being ſo eaſy of draught, that it will do double the work of any common plough, as experience has proved; and, with only one man and two horſes, will perform, even in ſtiff land, as much as two men and ſix horſes can do in a moderately light ſoil with any of the wheeled ploughs generally uſed, or indeed known in this country, where their great defect is, that they are too complex, and weigh too much upon the fore-crrriage, ſo that the friction of their wheels becomes a conſiderable addition to the draught: for the beſt plough certainly is that which is the moſt ſimple in its make and tackle; which requires the leaſt ſtrength to draw it, in proportion to the ſtiffneſs of the ſoil; which can be made always to cut to a proper depth; and which, by the ſhape of its mould-board, is beſt adapted to turn the furrow upſide down. The principle of the Kentiſh plough, with the ſhifting mould-board,

is,

is very good, where the land is dry, and will admit of it.

Meſſieurs de Chateauvieux and Duhamel, ever ſtudious to promote the welfare of mankind, have endeavoured to remedy theſe inconveniencies in wheeled ploughs, by the following improvements, which, with their uſual ſpirit of univerſal benevolence, they have moſt obligingly communicated to the world. We ſhall begin with the invention of the former of theſe gentlemen, becauſe it was rather prior, in point of time, to that of M. Duhamel.

The fore-part of M. de Chateauvieux's plough is compoſed of a wheel thirty-two inches in diameter, which may be extended to thirty-four inches, or reduced to thirty: but to fall ſhort of, or to exceed theſe meaſures, would be attended with inconveniencies. This wheel may be made very light, eſpecially if it be encircled with a thin hoop of iron. The plough itſelf is repreſented in Plate XXII. Fig. 1, 2, and 3, where Fig. 2. is the plan, and Fig. 1. the profile.

The frame in which the wheel is placed, is formed by two ſhafts AB CD, Fig. 2. diſtant from each other eighteen inches, from inſide to inſide; which fixes the length of the nave of the wheel. Theſe ſhafts are four feet eight inches long, and may be reduced to four feet four inches, by ſhortening them at the ends C and A. They are about two inches and a quarter ſquare: but the edges ſhould be rounded off. Theſe two pieces are faſtened together by the two croſs ſtaves EF, GH, which are two inches and a half wide, and about an inch thick. They are riveted to one of the ſhafts, at E and G, where they are not to be looſened at all; and at their other ends F and H, the ſhaft muſt be moveable, ſo as to be taken off, to let the two croſs ſtaves through two mortiſes in the beam IK of the plough; after which the ſhaft CD is put in its place, and fixed with two iron pins, *a*, *b*. Between the two ſhafts is placed the wheel LM, the nave of which is pierced through its center, with a hole proportioned to the thickneſs of the iron pin or ſpindle NO, which ſerves for an axle-tree, and is repreſented by the two pricked lines. This ſpindle, or axle-tree, the diameter of which is about three quarters of an inch, ought not to project beyond the outſide of the ſhafts, leſt it ſhould lay hold of or hurt the ſtalks of the corn, when this plough is uſed for ſtirring the earth between the rows in the New Huſbandry, as will hereafter be more particularly mentioned. To fix it at N, that end is flattened, and bent over the ſhaft to the middle of its upper ſide, where it is faſtened at *d*, by a ſmall pin driven through it and the ſhaft.

On the upper ſurface of each of the ſhafts, at the ends A and C, are the hooks A C, to which the harneſs is faſtened: and at the other ends B and D, are two rings, the uſe of which will be explained hereafter.

The ſhafts AB, CD, ſhould be pierced with four or five holes, to ſet the wheel more or leſs forward or backward, in order to make the plough ſtrike more or leſs deep into the earth, as may be ſeen in Fig 1. at *a*, *b*, *c*, and *d*. The ſame holes are indicated by the pricked lines on the two ſhafts of Fig. 2. from A to N, and from C to O.

The hind part of this plough conſiſts of the beam IK, Fig. 1, and 2. the ground-reſt CD, Fig. 1. which is covered by the ſhare LD; the handles KP, KQ, Fig. 2. and KP, Fig. 1. the ſheat EF, Fig. 1. of which part is pricked in Fig. 1. and the end appears at X in Fig. 2. the mould-board RS, Fig 2. part of which is ſeen at N in Fig. 1. the coulter GH, Fig. 1. and TV, Fig. 2. and the ſhare LD, Fig. 1. part of which is ſeen at Y, in Fig. 2.

The beam is four feet eight inches long, excluſive of the tenon which traverſes the handles. Three inches and a quarter ſquare are very ſufficient in its thickeſt part, which is from X to V, Fig. 2. The mortiſes in the beam, which are under *g*, *h*, and through which the two croſs-ſtaves EF, GH, are ſlipt, ſhould be ſo fitted, that the croſs-ſtaves may not ſhake or be looſe in them, at the ſame time that the beam ſhould, by their help, ſlip with eaſe over the croſs-ſtaves, either to the right towards EG, or to the left towards FH, according as the intended ploughing may require. The beam ſhould be faſtened, either by two nuts ſcrewed on at *m*, *n*, which will fix it tight to the croſs-ſtaves EF, GH; or by two iron pins ſtuck through the holes *p* and *q* in the two croſs-ſtaves, one to the right in the croſs ſtaff EF, and the other to the left in the croſs-ſtaff GH. Theſe pins will keep the beam ſteady in its place.

The lower part of the ground-reſt ſhould be ſomewhat concave, as is repreſented at CD, Fig. 4. in order to leſſen its friction againſt the earth.

The beam IK, Fig. 1. and the ground-reſt CD, are faſtened together by the ſheat FE, and the handles PK, both of which laſt are riveted to the ground-reſt by two ſtrong iron pins, the heads of which are ſeen at *g* and *h*; and to the beam, as alſo to the tenon of the beam which traverſes the handles at *m*, *n*; and by the two wedges, *p*, *o*, and *q*, another uſe of which will be explained hereafter.

Wood naturally crooked is beſt to make the handles of, that they may be all of one piece, which ſhould be ſo diſpoſed, that one third of the ſpace between the two handles, ſhould be left on the left ſide, and the two other thirds on the right ſide, in order to facilitate the plowman's walking in the furrow. This diſpoſition is ſhewed in Fig. 2. in which a line *e*, *f*, drawn from the middle of the beam, between the two handles, gives to the left ſide a third P*f*, of the diſtance PQ between the two handles, and the two other thirds *f*Q to the other ſide.

For want of wood naturally bent to a proper ſhape, theſe handles may be made of two pieces firmly riveted and faſtened together; and if it ſhould be more convenient to the plowman, the whole ſpace between the handles may be on the right-ſide, as in Fig. 6.

The ſheat EF, Fig. 1. ſhould be very ſtrongly and cloſely faſtened by its tenon to the ground-reſt, at *g*. An intelligent workman will eaſily make it of a proper ſize, which is about two inches and a half wide, and a full inch thick. The inclining of this piece with the ground-reſt, gives it greater ſtrength to reſiſt, than if it was faſtened to it at right angles.

The mould-board, repreſented by RS, Fig. 2. and AB, Fig. 7. is from thirty to thirty-one inches long, and ten inches high or deep. It ought to be placed as in Fig. 8, where its end A forms an acute angle, terminating at the junction of the fin of the ſhare: its other end B extends beyond the length of the ground-reſt, againſt which it ſhould incline, in ſuch manner that, ſuppoſing the ground-reſt to be lengthened out as far as C, the line CB would be twelve or thirteen inches long, reckoning from the

fartheſt lateral ſurface of the ground-reſt to the fartheſt lateral ſurface of the mould-board, which, being thus placed, will form the width of a furrow.

The lower part of this mould-board is ſloped a little inward, as is expreſſed by the ſhade in Fig. 7: and the part *b* Fig. 7, ſhould jet out at leaſt two inches beyond the part *a*. To this end, the mould-board ſhould be made of a plank about three inches thick, which will bear being ſcooped on one ſide and rounded off on the other, in order to give it the concavity without, and the convexity within, repreſented in Fig. 3. and 7.

The mould-board ſhould be well faſtened, to prevent its being diſplaced by the reſiſtance of the earth. The upright piece CD Fig. 7, which joins to the handles at its end D, and to the mould-board at its other end C, ſupports it ſtrongly. It is highly neceſſary to cover the part of the mould-board which bears upon the earth, with a thin plate of iron, in order to preſerve it; for otherwiſe it would ſoon be worn out.

The coulter GH, Fig. 1. ſhould be made of good iron well ſteeled. A notch is cut in the beam to receive it, as in Fig. 9 and 10; and as the corners of that notch, C and B, againſt which the coulter bears hardeſt when the plough works, would ſoon be worn away if the wood was left bare, it is proper to ſecure them with two ſmall pieces of iron AB, CD, about the ſixth part of an inch in thickneſs, ſcrewed on with flat-headed ſcrews. Theſe pieces of iron will keep the coulter ſteady in its place.

The coulter ſhould be pierced with ſeveral holes from E to F, Fig. 10, to take it higher up, or let it lower down, as occaſion may require. It is faſtened to the beam, which is pierced at E, Fig. 9, by a ſtrong iron pin with a ſquare flat head, which is let into the beam and lies even with it, as in Fig. 10. The other end of this pin, E, Fig. 10, is a ſcrew, fitted with its nut, by which the coulter is faſtened tight to the beam. Upon this ſcrew hangs the handle A, Fig. 1. which ſerves to turn it, and at the end of which is the key that faſtens on the nuts of the iron pins which ſecure the ſhare. By this means, the key to turn the ſcrews is always carried with the plough.

M. de Chateauvieux's coulters weigh but five or ſix pounds a-piece at moſt, and frequently not more than three pounds.

He places his coulter ſo that its point G, Fig. 1. projects about an inch beyond the outſide of the ſhare LC.

Fig. 12 repreſents the ſhape of the ſhare, with its dimenſions, as do alſo Fig. 13 and 14. The point of this ſhould be made of good ſteel, and the reſt of good iron, neither too ſoft, nor too high tempered, that it may not be ſubject to break or bend. The tail of the ſhare, AB, Fig. 12, ſhould be thickeſt from A to C, becauſe that is the part which bears the greateſt ſtreſs. Its thickneſs diminiſhes gradually to B, where the ſhare is faſtened to the ground-reſt. This tail is pierced with two round holes at A and B, Fig. 13, through which are put the iron pins DE, FG, Fig. 12. which have ſquare flat heads, lying even with the tail of the ſhare. Theſe pins paſs through the ground-reſt, where they are faſtened on the other ſide by the nuts EG. A third round hole may be added at *x*, Fig. 13, in order to faſten the ſhare ſtill more firmly to the ground-reſt, with a ſhort flat headed ſcrew.

M. de Chateauvieux has likewiſe made ſome ploughs with the round holes *ab*, Fig. 13, near A and B; that the iron pins DE, FG, Fig. 12, might not traverſe the tenons of the ſheat and handles; and inſtead of thoſe iron pins, he has riveted them with wooden pins, and found them keep the whole tighter together than the iron ones.

To the left ſide of the plough ſhould be faſtened the thin board N, Fig. 1 and 7, the uſe of which is to prevent the earth from tumbling over between the ſhare and the mould-board. As plowing wears the point of the ſhare, though it will not hurt this ſo much as it does that of the common plough, it muſt be new pointed from time to time, always obſerving to make the point incline a little towards the earth, as is repreſented by the pricked line DL, Fig. 1; that the ſhare may ſcarcely touch the ground at any other part than D and L, in order to leſſen the friction.

The hind part of the plough, thus formed, is joined to the fore carriage, by running the croſs ſtaves EF, GH, Fig. 2. through the mortiſes of the beams, *gh*; and is fixed there, either by the ſcrews *m n*, or the pins *p*, *q*. The traces of the firſt and ſecond horſe are faſtened to the hooks AC; and if a third horſe be uſed, the traces of that third horſe are faſtened to thoſe of the ſecond. Horſes will do better for this plough, than oxen, unleſs theſe laſt have been uſed to be harneſſed one before the other.

The plough thus equipped, may eaſily be carried to the field, if its hind part is laid upon the little carriage ÆW, Fig. 2. conſiſting of an iron axle-tree ÆW, two ſmall wheels *ki*, *lr*, and the two pieces B*t*, D*v*, at the end of which are the hooks B and D. Theſe wheels are about twenty-one inches, or two feet in diameter; and three feet ſix inches, or even four feet aſunder. They are very light, having but a ſmall weight to bear. The hooks of theſe two pieces B*t*, D*v*, are inſerted in the rings B and D at the end of the ſhafts; and by this means the plough will be carried upon three wheels, of which Fig. 1 and 2 ſhew ſufficiently the arrangement and uſe. Fig. 5, ſhews the ſlope that ſhould be given to the upper ſurface of the middle of the axle-tree of this ſmall carriage, on which the reſt of the plough is to be loaded in order to remove it from one place to another, that the ground-reſt and other pieces may lie flat and ſteady upon it.

To open the firſt furrow with this plough, the wheel muſt be placed at the laſt hole, towards the extremity of the ſhafts. This makes the ſhare incline the more, and conſequently cut the deeper. But as it would be ſomewhat troubleſome to change the poſition of the wheel, at every firſt cut of the plough, a very little attention will remedy that inconvenience. It is only inclining the handles of the plough to the right or left, inſtead of holding them even. The whole plough will incline with the handles, and the ſhare will then enter into the ground with eaſe, and open the firſt furrow. The other furrows are plowed without any ſort of difficulty; and for them, the plough is to be held even, or inclined but very little, either to the right-hand or the left, as the ſituation of the land may require.

M. de Chateauvieux generally reſts the beam on the left-hand ſide of the fore-carriage. It is eaſy to place it ſo as to leave whatever diſtance is thought proper between the outmoſt row of corn and the furrow that is actually plowing.

The forwarder the wheel is ſet, the deeper the plough cuts; and ſo on the contrary. But if one would have it cut ſtill deeper, or ſhallower, than it can be made to do by altering the poſition of the wheel, that too may eaſily be effected. By looſening a little the wedge above the beam

beam *p*, *o*. Fig. 1. and driving farther in the wedge, *q*, the plough will cut leſs deep: as, on the other hand, the ſhare will be more inclined, and therefore cut deeper, if the wedge *q* under the beam is looſened, and the wedge *p*, *o*, over it is driven in tighter.

The chief differences between M. de Chateauvieux's plough, and that of M. Duhamel, are as follow.

1. The beam of this laſt, ABC, Fig. 1. Plate XXIII. bends from C to B; whereas that of M. de Chateauvieux's is nearly ſtrait all along.

2. In conſequence of this bending, the hindmoſt extremity of M. Duhamel's beam is joined at B to the hindermoſt part of the ground reſt E, after paſſing through a mortiſe F, in the lower part of the handles: ſo that this beam is joined to the ground-reſt by its extremity B, the bottoms of the handles F, and the ſheat G; whilſt that of M. de Chateauvieux's plough, is joined to the ground-reſt by this ſheat, another which this plough has not, and the lower part of the handles: for the beam does not anſwer to the ground-reſt.

3. The mould-board HI, Fig. 2. of this plough, is lighter than that of M. de Chateauvieux's, and differently ſhaped.

4. The two handles KK, are at equal diſtances from the beam, and are joined together by a croſs ſtaff M.

5. The ſhare N, Fig. 3. is pretty much like that of M. de Chateauvieux's plough, but ſhorter and narrower; ſo that it cuts leſs wide furrows; which M. Duhamel rightly thinks the beſt way of plowing.

6. The coulter O of this plough paſſes through a mortiſe in the beam, which is there ſtrengthened by hoops of iron, to prevent the beam's being ſplit by the driving in of the wedges PP which fix the coulter.

M. Duhamel thinks this hind part of his plough preferable to that of M. de Chateauvieux's, for light lands: but it would not do ſo well in ſtiff ſoils, becauſe the earth would be apt to clog about the ſheat at Q; whereas it is thrown off by M. de Chateauvieux's plough. M. Duhamel likewiſe approves of making the beam ſtrait as M. de Chateauvieux's is, inſtead of giving it the bending from C to B, eſpecially for ſtiff lands.

7. The beam CA, is fixed to the croſs ſtaves RR of the fore-carriage of this plough, by the ſcrews and nuts SS.

8. The ſhafts TT, are faſtened before by a croſs ſtaff V, which gives great ſolidity to the fore-carriage, and cannot be added to M. de Chateauvieux's plough; not only becauſe the wheel is too large, but likewiſe becauſe it muſt be ſet forwarder or backwarder, in order to make the ſhare cut more or leſs deep.

The wheel of this plough is not ſo large as that of M. de Chateauvieux's, becauſe the axle-tree, inſtead of being inſerted in the ſhafts TT, is let into the ſide pieces X, Fig. 4. which are faſtened to the ſhafts by the ſcrews and nuts YY.

The advantages of having the wheel ſmaller, are, 1. That the plough is leſs apt to lean too much on its ſide, and is more eaſily held upright; 2. That the croſs-ſtaff V may be added to the fore-carriage, by which it is rendered more ſolid; and 3. That the fore-carriage may be made ſhorter than it otherwiſe could be.

The bare inſpection of the draught of this plough, ſhews that it is made to cut more or leſs deep, by ſcrewing the nuts Y more or leſs tight, and putting a thicker or thinner wedge between the ſide piece X and the ſhaft; which is an eaſier and quicker way, than changing the ſituation of the wheel. But ſtill, a readier method is, to have under the ſhafts TT, a falſe ſhaft ZZ, Fig. 5. fixed with hinges, &c. for then, by only ſticking the peg *a*, into one of the holes *b*, the beam is raiſed or lowered, in a moment, to whatever degree is thought proper, without altering the poſition of the wheel.

It is likewiſe evident, that in order to give the ſhare a greater or leſs degree of entrance into the earth, nothing more is requiſite than to place the beam nearer to, or farther from, the right-hand ſhaft: for the horſes, which are harneſſed one before another, go, as does alſo the wheel, in the laſt made furrow, and the plowman goes in the furrow actually making.

dd. Are hooks to faſten on the harneſs of the horſes.

ee. Cramps to faſten the fore-carriage.

ff. Pins to fix the beam to the ſheat.

gg. Pegs to faſten the croſs ſtaves.

h. A ſtrong pin which goes through the hole *i*, to keep the mould-board ſteady.

Four coultered PLOUGH, an inſtrument invented by Mr. Tull, being an improvement on the common plough, that makes it cut the pieces of earth into four; that is, it thus divides the earth four times as ſmall as the common plough.

The common two-wheeled plough has of late years become univerſally uſed in many countries, and is found greatly preferable to the ploughs they uſed before; there is an objection to it, indeed, in regard to ſome ſtiff and miry lands, in which the wheels become clogged up, and cannot turn. This, however, is eaſily remedied by twiſting thumb ropes of ſtraw about the iron circle and ſpokes of the wheels; theſe ſpreading as they turn, and, as the circle twiſt bears upon the ground, throw off the dirt, and never clog. The two principal parts of this plough are the head and the tail: the plough-head contains the two wheels and their axis, or ſpindle, paſſing through a box, and turning round both in it and in the wheels.

There are fixed perpendicularly in this box two crow-ſtaves, as they are called, which are flat and narrow boards, each having on it two rows of holes, whereby to raiſe or ſink the beam of the plough, by pinning up or down the pillow, to increaſe and diminiſh the depth of the furrow. Behind are a pair of gallows, through which the crow-ſtaves paſs at the top by mortiſes, into which they are pinned; and to theſe are faſtened what are called the wilds, which are rings and crooks of iron, by which the whole plough is drawn in the working. From the box to the center of the beam there is carried an iron-chain, conſiſting of four, five, or more long links, and called the tow-chain: this faſtens the plough-tail to the plough-head. It is fixed to an iron collar, faſtened in the beam at one end, and at the other paſſes through a hole in the middle of the box, and is pinned in with a wooden pin.

From the ſame iron-collar to which the tow-chain is fixed, there is alſo another chain faſtened, called the bridle-chain: this runs above the beam, as the tow-chain does below it, and is compoſed of ſmaller and more numerous links. At the upper end, as the tow-chain enters the box of the plough, this bridle-chain is fixed to the top of what is called the ſtake of the plough: this is a perpendicular ſtick, carried up parallel with the left crow-ſtaff, and pretty near it, and faſtened to it by a wyth or rope, or by the end of the bridle-chain itſelf, when that is long enough. This ſtake is alſo faſtened in its lower part, under the

the gallows, to the ſame crow-ſtaff, by another wyth or piece of rope.

Theſe are the parts of which the head-part of the plough is compoſed. The plough-tail conſiſts of the beam carried from the head to the very extremity, and ſerving as the ſupport and baſe of all the reſt. A little below the collar to which the tow-chain and bridle-chain are faſtened, this beam is pierced with a large hole, which lets through the coulter: this is a long and narrow piece, terminating in an edge, and reaching juſt to the ſhare; and it is fixed immoveably in its place by means of a wedge which is driven into the hole of the beam with it: the office of this coulter is to cut the earth as it is thrown up by the ſhare. Behind theſe, the ſame beam is pierced with two more holes, one very near its end: theſe give paſſage to two oblong pieces, called the fore-ſheat and hinder-ſheat, by which the plough-ſhare is ſupported in its place. To the top of the hinder-ſheat there is faſtened a ſhort handle by a wooden pin. Parallel to the hinder-ſheat there runs up a piece of wood of much the ſame form, called the drock; and to this is faſtened another horizontal piece, called the ground-wriſt: theſe are all on the right-hand ſide of the plough, and parallel with the fore-ſheat. There runs another piece of much the ſame form with it, on the right-hand; and the bottom of this is the earth-board. The long handle of this, which reaches as far as that of the ſheat, is faſtened to the drock by a pin, the other end of which goes into the beam. Near the lower end of the fore-ſheat, there are two flat pieces of iron, which paſs from the two ſides of it up to the beam; and being let through it, are faſtened to the upper part by ſcrews and pins. Theſe keep the ſheat in its place.

The ſtructure of the four-coultered plough is different, in ſome reſpects, from this, though in general founded on it. Its beam is ten feet long, whereas that of the common plough is but eight. The beam is ſtraight in the common plough, but in this it is arched in one fourth part of its length, near the plough-head. At the diſtance of three feet two inches from the end of the beam at the plough-tail, the firſt coulter, or that next the ſhare, is let through; and at thirteen inches from this, a ſecond coulter is let through: a third at the ſame diſtance from that; and, finally, the fourth at the ſame diſtance from the third, that is, thirteen inches.

The crookedneſs of the upper part of the beam in this plough is contrived to avoid the too great length of the three foremoſt coulters, which would be too much, if the beam was ſtraight all the way; and they would be apt to bend and be diſplaced, unleſs they were vaſtly heavy and clumſy. Aſh is the beſt wood to make the beam of, it being ſufficiently ſtrong, and yet light.

The ſheat in this plough is to be ſeven inches broad. The fixing of the ſhare in this, as well as in the common plough, is the niceſt part, and requires the utmoſt art of the maker; for the well going of the plough wholly depends upon the placing of this. Suppoſing the axis of the beam, and the left ſide of the ſhare, to be both horizontal, they muſt never be ſet parallel to each other; for, if they are, the tail of the ſhare, bearing againſt the trench as much as the point, would cauſe the point to incline to the right-hand, and it would be carried out of the ground into the furrow. If the point of the ſhare ſhould be ſet ſo, that its ſide ſhould make an angle on the right ſide of the axis of the beam, this inconvenience would be much greater; and if its points ſhould incline much to the left, and make too large an angle on that ſide with the axis of the beam, the plough would run quite to the left-hand; and, if the holder, to prevent its running quite out of the ground, turns the upper part of his plough toward the left-hand, the pin of the ſhare will riſe up, and cut the furrow diagonally, leaving it half unploughed. To avoid this and ſeveral other inconveniencies, the ſtraight ſide of the ſhare muſt make an angle upon the left ſide of the beam; but that muſt be ſo very acute a one, that the tail of the ſhare may only preſs leſs againſt the ſide of the trench than the point does.

The great thing to be taken care of, is the placing the four coulters; for on this the ſucceſs of the whole depends. Theſe muſt be ſo ſet, that the four imaginary planes deſcribed by their four edges, as the plough moves forward, may be all parallel to each other, or very nearly ſo; for if any one of them ſhould be very much inclined to, or ſhould recede much from either of the other, then they would not enter the ground together. In order to the placing them thus, the beam muſt be carefully pierced in a proper manner. The ſecond coulter-hole muſt be two inches and an half more on the right-hand than the firſt: the third muſt be as much more to the right of the ſecond, and the fourth the ſame meaſure to the right-hand of the third: and this two inches and an half muſt be carefully meaſured from the center of one hole to the center of the other. Each of theſe holes is a mortiſe of an inch and a quarter wide, and is three inches and an half long at the top, and three inches at the bottom. The two oppoſite ſides of this hole are parallel to the top and bottom, but the back is oblique, and determines the obliquity of the ſtanding of the coulter, which is wedged tight up to the poll. A perſpective view of this curious plough the reader will find in Plate XXI. Fig. 9.

The coulter is two feet eight inches long, before it is worn; the handle takes up ſixteen inches of this length, and is allowed thus long, that the coulter may be driven down as the point wears away. *Tull's Horſe-hoeing Huſbandry.*

Double PLOUGH, an inſtrument invented by Mr. Randal, which, by putting the ſhare point to the middle of the interval left by the horſe-hoe, throws the mould on each ſide of it, at the ſame time, towards the rows, and earths them up to what degree the ploughman pleaſes, in order to nouriſh them on to perfection. If a common plough, inſtead of the ſingle hough, was uſed, the furrows would be turned into the middle of the interval, and appear in the form of a ſingle ridge: and if the plough went twice in a place, to deepen the ſoil, the ridge in the middle would be proportionably higher, and the ground ſtrangely improved by ſuch operations, and the vegetables ſurpriſingly promoted in their growth. In either of theſe caſes, of the plough's going once or twice in a place, the double plough, by taking faſt hold of the mould, throws all back again; and if the vegetables are not effectually earthed up, which may be the caſe after double ſpitting the intervals; then running the double plough over again, compleats the buſineſs, and ſtrangely toſſes about and mellows the mould. This, in general, is the uſe of this plough in earthing up vegetables, that have three feet intervals.

But under the name of this double plough, we are to underſtand another of the ſame form, much narrower in the tail, to perform what is called ridge-work, which is either ſingle, or double: if ſingle, this double plough works alone, throws up the ridges, and, at a proper time,

ſplits

ſplits them, and throws them back into the trenches; and this toſſes the mould backwards and forwards, which, by theſe agitations, and other operations, is made ready for cropping, as is particularly mentioned in my Treatiſe. If theſe ridges are to be double, that is, if there is to be double ſpitting, then the double plough performs as before, and goes as deep as is conſiſtent with the intereſt of the man's arms, and the horſe's eaſe. Here the worthy ploughman is requeſted to keep his hands even, that the plough may run flat upon its ſole, and clear the trench of mould, as far as neceſſary, which it is made to do in that poſture, to make way for the lifting-plough, of the ſame breadth in the tail. *See* Plate XXI. Fig. 10.

Double Lifting-PLOUGH. My earneſt deſire, ſays Mr. Randal, to imitate gardeners, in preparing the ſoil, by their always going a good depth, and which to be ſure, is the true biaſs of nature, in regard that vegetables, in general, require a looſer habitation, beneath the ſoil, to greater depth than farmers will allow them: this deſire produced the lifting-plough, to raiſe the generous mould that lies far beneath the reach of common ploughing, into general uſe. This I have practiſed to very great effect, and never failed doing it, in all the going ground of the tenures of near a thouſand acres, where the ſtratum, below the uſual ſoil, would give me this deſirable and encouraging advantage. Hence it was, that I was always extremely fond of this lifting-plough, which never fails of ſucceſs in the hands of an honeſt, worthy ploughman; and, no doubt, there are many ſuch to be found. I was very imprudent, in my firſt conſtruction of this plough, in having it made too large, in order, through a covetous diſpoſition, to have much work done in a day. The draught was ſo fatiguing to the horſes and men, that the invention was under a good deal of diſrepute, and I was in danger of having all the ſervants leave the ſervice, and of killing the horſes: for theſe reaſons, I was obliged to ſit down with that loſs, great as it was, in the purchaſe of this plough, and contract all the proportions of it, to make the draught quite eaſy to the team and men; and then there was not the leaſt complaint heard, but only a backwardneſs to proceed, which uſe effectually removed.

Here, then, this lifting-plough is to go into all the trenches made by the double plough, as mentioned before; and as the ploughman deepens the trenches as far down as is conſiſtent with his own and horſes eaſe, the irons, running up on each ſide of the plough, will lift up the mould, which will be thrown, by the motion, upon the old ridges. The ground now lies in deep trenches, and high ridges; and this is what is called, in my Treatiſe, double ridges; and how the ſoil is to be afterwards reduced to a level, and receive farther management, is therein particularly mentioned. Now, from the conſtruction of theſe two ploughs, the ſoil beneath will, if the ploughman keeps his hands even, be cut level, inſtead of leaving there hills and dales, but too often practiſed, to the diſcouragement of the growth of the vegetables. *See* Plate XXI. Fig. 11. *Randal's Semi-virgilian Huſbandry.*

PLOUGHING, the action of breaking up, and looſening the ſoil.

"The principle, ſays M. de Chateauvieux, of thoroughly dividing and looſening the ſoil, is ſo generally received, that there is not a farmer, who does not know, that one ploughing more than ordinary is of as much ſervice to his ground, as dunging it would be. Experience muſt have ſhewn them, that his crops are increaſed by this extraordinary ploughing: but he is not ſufficiently ſenſible, that of all the ways of improving his land, no one is more effectual, or leſs expenſive than this. Were its full value known, it would be more generally practiſed, and every huſbandman would give all his lands at leaſt one ploughing extraordinary.

"To ſatisfy myſelf of what might be done with the plough alone, I reſolved to make a trial on a ſpot of ground which I knew to be incapable of naturally producing any thing. Some years before, I had dug away the earth, three feet deep, from a ſpace of ſixty ſquare perches. Nothing remained in it but a white clay, like that which potters uſe. This ſpot, thus circumſtanced, ſeemed to me a proper one for my experiment. As the ſpace was too ſmall for a plough to work in, I had recourſe to the ſpade and hoe. The ground was laid out in beds, which were afterwards ſowed with wheat, and the ſpaces between them were frequently ſtirred. The firſt year, my plants were very poor, and branched into only two, three, or four ſtalks apiece. In the ſecond year, they did much better; and in the third, they were as large and fine as any my garden could have produced. This ſpot ſtill continues to produce equally well; the ſoil is now like fine mould; and, which is very remarkable, it has loſt its former white colour, and is become black. We have here a ſtrong inſtance of what may be done by pulverizing the earth. Let us but do the ſame with any of our bad lands, and perſevere in ploughing and ſtirring them a ſufficient time; the ſucceſs will not be doubtful.

"To be ſtill farther convinced of the truth of this important maxim in huſbandry, that the earth ſhould be thoroughly looſened by deep and frequent ploughings, I examined very carefully, whether my lands which had been prepared by repeated ploughing only, without the aſſiſtance of any dung or manure, were more looſened and rendered lighter, than thoſe which were under the common management. All my obſervations proved that they were. The firſt glance of my eye ſhewed me, that their ſurface was ſmoother; on ſounding the furrows, I found them deeper; and much leſs ſtrength was required to plough them; two horſes, or ſometimes only one, or a ſingle ox, doing here with eaſe, what would otherwiſe have employed double that number of cattle: a manifeſt proof that my grounds were in excellent tilth; whereas the common fields offered nothing pleaſing or ſatisfactory to the eye; the earth there was extremely hard, cloſe, and compact, and its ſurface almoſt as firm as that of a beaten road. The ground which had been well and often ploughed remained ſo light and ſoft, after its crop of wheat was taken off, that I thruſt a ſtick of green willow eight or ten inches deep into it without the leaſt difficulty, though I could not by any means puſh it at all into the land cultivated in the common way."

Camillo Tarello, a native of Lonato, in the Venetian territoies, concerned to ſee the neglected and dreadful miſmanaged ſtate of huſbandry in his country, wrote his ſmall, but highly valuable treatiſe of Agriculture, and preſented it to the ſenate of Venice under the title of *Ricordo d' Agricultura.* The ſenate, in juſtice to the excellency of this work and the patriotic intentions of its author, granted him, on the 29th of September 1566, not only the ſole right of vending his book, but alſo ordered at the ſame time that all ſuch as adopted his

new method of husbandry, should pay to him, and afterwards to his descendants, four marchetti (about three halfpence of our money) for every acre of corn land, and two marchetti for every acre of other land, planted according to his direction. The Berne Society have favoured the public with the first part of Tarello's excellent treatise; and we shall take from thence the following extract as a farther proof of the necessity of thorough ploughing.

"When we consider, says that good patriot and intelligent husbandman, Camillo Tarello, that every ear of wheat yields fifty grains (we will suppose that to be the medium number), we may infer, that if all these were sowed and grew, we should reap fifty times as much as was sown: but our crops are far from being so abundant. This failure cannot proceed from any other cause than that all these grains do not rise and prosper; nor can any but one, or all, of the seven following reasons be assigned for it, if we except bad seasons and extraordinary accidents.

"The deficiency arises either 1, from the seed; or 2, from rain, when the corn is in bloom; 3, from winds, when its stalks are large; 4, from birds, which eat up the grains that have been sown; 5, from worms and insects; 6; from the earth; or, 7, from the cultivator himself.

"The cause of this defect is not in the seed: for, either the seed is good, or it is not: if it be not good, the grains will not rise at all; but if it be good, as we suppose it to be, each grain may, and should, produce at least one ear. Another proof is, that if a parcel of seeds are planted at a proper depth, one by one, in holes made on purpose for them, and an equal number of the same kind of seeds are sowed at random in the same sort of ground, all the former will rise, but not all the latter.

"Neither ought it to be ascribed either to rain or winds, at the time of the blossoming of the corn: because we do not reap fifty for one, even when the weather is then very fine; and even when each ear bears fifty grains, we do not reap fifty times the seed.

"Nor ought we to accuse the birds of the air: it being well known that lupins, which they never touch on account of their bitterness, do not all rise; for if they did, the crop would be still more considerable, as each of these plants bears from fifty to sixty seeds. Besides, what the birds eat is not considerable.

"Worms and insects are not the cause, for three reasons, first, our crops are very little better even when neither worms nor insects are to be seen; secondly, the case here is the same as that of the lupins; and, thirdly, the worms would ravage whole fields (as they sometimes do) in so visible a manner, that it would be easy to distinguish the cause of the mischief. However, this is an extraordinary and pretty rare event.

"The same may be said of fogs, cold, bad weather, reptiles, and other mischievous creatures. Though these enemies do not injure our fields every year, we nevertheless constantly reap less corn than they might be made to produce.

"Lastly, the earth is not in itself the cause of this scantiness of increase: for the Creator has endowed it with perpetual youth and fruitfulness, as Columella justly and prettily observes in the first chapters of his first and second books. The earth and nature are always the same.

"Now, if the usual cause why we do not reap fifty for one cannot be imputed to either of the things above-mentioned, it must of necessity be sought for in the ignorance, negligence, and indolence of the husbandman: for our practise is diametrically contrary to that of the ancient Romans. They plowed often, and sowed little: yet every family lived upon the produce of its small farm: but we who plow little and sow a great deal, are always disappointed."

The Romans were not only extremely attentive to the thorough culture of their land, but also, even in the latter time of the republic, laid it down as a maxim to be followed by all good husbandmen, "to sow but little and plow much." This is strictly enjoined by Virgil; and Pliny, who instances the husbandry of Cresinus, as an example of the good effects of this practice, laments the deplorable condition of Italy, when rich men, with the help of their numerous slaves, farmed large districts of land; because it diminished the number of Roman citizens, and rendered the country less fruitful: for, as both he and Columella observe, the Romans then became dependant on other nations for the means of subsistance.

May not this naturally lead us to cast an eye upon our own country, where, of late years, gentlemen throw their estates, as much as possible, into large farms, which, in the language of Mago the Carthaginian, must, in general, render the farm stronger than the farmer, whereby it necessarily becomes less fruitful? This practice is attended with another most fatal consequence to a manufacturing and trading people: it lessens the number of inhabitants in the country, from whence only the supply of population arises; for cities and large towns are always an expence of men.

Whilst we bestow this due commendation on plowing, we do not mean to recommend it on Mr. Tull's principles, "that dividing and pulverizing the earth is all in all." When the earth is in fine tilth, so that the roots of plants can easily extend themselves every way, an advantage arises, which is thus described by the ingenious M. J. J. Biberg, in his Œconomy of Nature.

"Plants, as well as living creatures, must submit to death. They spring up, they grow, they flourish, they ripen their fruit, they wither, and at last, having finished their course, they die, and return again to the dust, from whence they first took their rise. Thus the black mould which we see upon the surface of the earth, is chiefly owing to dead vegetables. For all roots descend into the earth by their branches, and after a plant has lost its stem, the root remains; but this too rots at last, and changes into mould. By this means, this kind of mould is mixed with the earth, by the contrivance of nature; nearly in the same way as dung thrown upon fields is wrought into the earth by the industry of the husbandman.

"The earth thus prepared offers again to plants from its bosom, what it had received from them. For when seeds are committed to the earth, they draw to themselves, accommodate to their nature, and turn into plants, the more subtile parts of this mould, by the co-operation of the sun, air, and moisture; so that the tallest tree is, properly speaking, nothing but mould wonderfully compounded and modified by a virtue communicated to a small seed by the Creator. From these plants, when they die, just the same mould is formed, as give birth to them originally; but in such a manner, that it is in greater quantity than before, if the earth be kept loose to admit of the free extension of the roots. Vegetables therefore increase the black mould; whence fertility remains continually uninterrupted: whereas the earth would not make good its

annual

annual conſumption, if it were not conſtantly recruited by new ſupplies."

The illuſtrious M. Lullin de Chateauvieux, to whom the world in general is infinitely indebted for ſome of the moſt judicious and beſt executed experiments ever made in Agriculture, as is his native country in particular for his excellent adminiſtration in the high office of chief magiſtrate of the republic of Geneva, is the firſt writer who has attended to the advantages of ſtubble as a manure.

Towards the latter end of the year 1753, walking over his grounds after harveſt, he was ſtruck with the difference which he found in the ſtubble of his own experiments, and that of the corn which had been raiſed in the common way. This laſt was ſo poor and weak, that it ſcarcely oppoſed the motion of his feet, while the other reſiſted greatly. "I often felt it break, ſays he, under my feet, and frequently met with tufts of twenty, thirty, forty and ſometimes more ſtalks, which ſtopt me ſhort, like ſo many little buſhes. I am the more particular in my account of this ſtubble, becauſe it ſhews the great ſtrength of the plants, which they would not have had if the earth had not been well prepared. Beſides, it has its real uſe: for thorough plowing ſupplies the want of dung, not only by keeping the earth conſtantly in a looſe ſtate, but likewiſe by the quantity of ſtrong ſtubble which it produces, and which affords a moſt excellent manure attended with no expence. It lies ready upon the ſpot; the plowing of the earth buries it; and as it is a long time in rotting, it helps to keep the ſoil looſe and light, and is repeated every year. I have found ſtubble almoſt whole at a year's end, and have ſeen ſome not quite conſumed at the end of two years. From what I have ſeen of its effects, I will venture to ſay, that it contributes greatly to increaſe the productions of the earth. I have very often plucked up plants remarkable for their beauty, and have frequently found their roots interwoven with tufts of ſtubble, which ſhewed me the cauſe of their extraordinary growth."

"It is often, ſays Mr. Duhamel, more advantageous to increaſe the fertility of land by plowing, than by dung: 1, Becauſe, in general, only a certain quantity of dung can be had, the product of twenty acres being ſcarcely ſufficient to produce enough for four or five; whereas the particles of the earth may be divided and ſubdivided almoſt to infinity. The help derived from dung is therefore limited; whilſt no bounds can be ſet to the benefits that may accrue from plowing.

"2, Few plants raiſed in dung ever have the fine flavour of thoſe which grow in a good ſoil moderately dunged. Our kitchen gardens and our other grounds afford daily inſtances of this truth. Pulſe, pot-herbs, and fruit, are ſeldom ſo good in the neighbourhood of great cities, where dung abounds, as in country gardens, where but little of it is uſed. The corn raiſed in thoſe exceſſively dunged lands, yields a great deal of bran, and not much fine flour, and is difficult to keep. Nice horſes will not eat oats of the growth of fields manured with human ordure. But nothing is ſo ſtriking as the difference between the wine of an undunged vineyard, and that of vines which have been greatly dunged.

"3, Dung, which is ſuppoſed to act by fermentation, cauſes indeed an inward diviſion of the particles of the earth, which muſt be very uſeful, as well as the food which it furniſhes to plants: but the plough, beſides dividing thoſe particles, changes their ſituation, and turns the ground upſide down, ſo that the part which was expoſed to the influences of the air and dews, takes the place of another part, which is brought from within the earth, up to its ſurface. The conſequence of this is, that well-ploughed land is not exhauſted by weeds, and that it admits the moiſture of rains and dews, together with the rays of the ſun, all of which contribute greatly to render it fertile, as has been proved by very many experiments.

"4, Dung attracts inſects, and thoſe inſects gnaw plants. It is well known that the roots of trees planted in dunged ground, are very liable to be damaged by inſects; and this is one of the chief reaſons why floriſts baniſh dung from their gardens. Worms, grubs, and other ſuch like vermin, make dreadful havock in their beds of flowers; and I have ſeen meadows where the graſs has been entirely deſtroyed, by their eating its roots.

"I muſt add, that moſt ſorts of dung contain a great many ſeeds, which fill the land with weeds.

"5, It is true that dung is equally ſerviceable to light lands, and to ſtrong; but the ſame may be ſaid of plowing.

"Land is too ſtrong when its particles lie ſo cloſe together, that the roots of plants cannot extend between them, without great difficulty, in queſt of their neceſſary food, for want of which they will remain poor and ſickly. But when the ground has been well looſened by repeated plowings, and its particles are ſet at greater diſtances from each other, thoſe roots will be able to ſpread freely on all ſides, to pervade every minute chaſm, and to collect ſuch quantities of food, as will make the plants grow ſtrong and vigorous. The friendly influences of the atmoſphere will then penetrate to them. What plainly proves the good effects of looſening ſuch ſoils, is, that their fertility is ſometimes increaſed by a mixture of ſand, inſtead of dung. Now ſand does not afford any nutritive ſubſtance; but only hinders the particles of the earth from re-uniting too cloſely.

"Plowing is equally beneficial to light lands, for the very contrary reaſon; though theſe do not require ſo much of it as the other. There is no danger of their being exhauſted by any expoſure to the ſun; but, on the contrary, they acquire an additional degree of fertility by the ſtirring and grinding of their particles, and are thereby the better fitted to receive the moiſture of rains and dews, and the ſalutary influences of the air and ſun; whilſt their inward pores are at the ſame time better adapted to the proper extenſion of the roots of plants, by their being leſſened.

"But, let the benefits ariſing from dung be ever ſo great, let the means of obtaining enough of it be ever ſo eaſy, and let even its defects be corrected as much as can be; ſtill it will not be the leſs true, that frequent plowing is of infinite ſervice to land.

"For this reaſon it is, that land intended for wheat is plowed three or four times before the grain is ſowed. Some farmers, who could not dung all their lands, plowed part of them double the uſual number of times, and reaped greater crops from theſe, than from thoſe which were dunged. The expence of three plowings extraordinary will be much leſs than the price of the dung neceſſary for the land, if the farmer is obliged to purchaſe it.

"In 1759, M. Delu gave three plowings to ſome of his fields intended for oats; and though that year was very dry and unfavourable to ſpring-corn, his oats kept up well till they were perfectly ripe, and yielded a full crop of excellent grain.

"He gave five plowings to a piece of wheat-land,

which had not been dunged, and, at harveſt, had taller and finer corn there, than in the neighbouring grounds which had been dunged and cultivated in the uſual way.

" In ſhort, the advantage of thorough tillage, while the plants are growing, is ſo great, that, in many places, it has been found amply to repay even the expence of digging between the rows of corn."

PLOUGH-WRIGHT, a perſon whoſe buſineſs it is to make ploughs, and other implements of huſbandry.

POA, meadow graſs, or that common ſpecies of graſs, that principally forms the green covering of our fields.

POCKET, a large ſort of bag in which wool is packed up, in order to be ſent from one part of the kingdom to the other.

POD, a term uſed to expreſs a pericarpium, conſiſting of two valves, which open from the baſe to the point, and are ſeparated by a membranaceous partition from which the ſeeds hang by a kind of minute ſtalk.

POKE, a ſack, or bag.

Hop POLES, the upright poles, or pieces of wood, round which they bind, twiſt, and ſupport themſelves. *See the article* HOP.

POLLARD, or *Pollanger*, a tree that has been frequently polled or lopped, and its top taken off.

POLL-EVIL, an abſceſs near the poll of a horſe, formed in the ſinuſes between the noll bone, and the uppermoſt vertebræ of the neck.

If it proceeds from blows, bruiſes, or any external violence, at firſt bathe the ſwelling often with hot vinegar; and if the hair be fretted off with an oozing through the ſkin, make uſe of two parts of vinegar, and one of ſpirit of wine; but if there be an itching with heat and inflammation, the ſafeſt way is to bleed, and apply poultices with bread, milk, and elder flowers: this method, with the aſſiſtance of phyſic, will frequently diſperſe the ſwelling, and prevent this evil.

But when the tumour is critical, and has all the ſigns of matter, the beſt method then is to forward it by applying the ripening poultices already taken notice of, till it comes to maturity, and burſts of itſelf; or if opened with a knife, great care ſhould be taken to avoid the tendinous ligament, that runs along the neck under the mane: when matter is on both ſides, the opening muſt be made on each ſide, and the ligament remain undivided.

If the matter flows in great quantities, reſembles melted glue, and is of an oily conſiſtence, it will require a ſecond inciſion, eſpecially if any cavities are diſcovered by the finger or probe; theſe ſhould be opened by the knife, the orifices made depending, and the wound dreſſed with the common digeſtive of turpentine, honey, and tincture of myrrh, and after digeſtion with the precipitate ointment; or waſh the ſore with the following, made hot, and fill up the cavity with tow ſoaked in it.

> Take vinegar or ſpirit of wine, half a pint, white vitriol diſſolved in ſpring water, half an ounce, tincture of myrrh, four ounces.

This may be made ſharper by adding more vitriol; but if the fleſh is very luxuriant, it ſhould firſt be pared down with a knife before the application; with this waſh alone Mr. Gibſon has cured this diſorder without any other formality of dreſſing, waſhing with it twice a day, and laying over the part a quantity of tow ſoaked in vinegar and the white of eggs beat together. This laſt application will ſerve inſtead of a bandage, as it will adhere cloſe to the poll, and come off eaſy when there is occaſion to dreſs. Some waſh with the phagædenic water, and then fill up the abſceſs with looſe doſſils of tow ſoaked in Ægyptiacum and oil of turpentine made hot, and continue this method till the cure is effected.

But the moſt compendious method of cure, is found by obſervation to be by ſcalding, as the farriers term it, and is thus proſecuted when the ſore is foul, of a bad diſpoſition, and attended with a profuſion of matter.

> Take corroſive ſublimate, verdigreaſe in fine powder, and Roman vitriol, of each two drams; green copperas half an ounce; honey or Ægyptiacum two ounces, oil of turpentine and train oil, of each eight ounces; rectified ſpirit of wine four ounces: mix together in a bottle.

Some make their ſcalding mixture milder, uſing red precipitate inſtead of the ſublimate; and white vitriol inſtead of the blue; the following has been ſucceſsfully uſed for this purpoſe, viz. half an ounce of verdigreaſe, half a pint of train oil, four ounces of oil of turpentine, and two of oil of vitriol.

The manner of ſcalding is firſt to clean the abſceſs well with a piece of ſponge dipped in vinegar; then put a ſufficient quantity of the mixture in a ladle with a ſpout, and when it is made ſcalding hot, pour it into the abſceſs, and cloſe the lips together with one or more ſtitches. This is to remain in ſeveral days, and if good matter appears, and not in an over great quantity, it will do well without any other dreſſing, but bathing with ſpirit of wine; if the matter flows in great abundance, and of a thin conſiſtence, it muſt be ſcalded again, and repeated till the matter leſſens and thickens.

Theſe liquid corroſive dreſſings agree well with horſes, whoſe fibres are ſtiff and rigid, and whoſe juices are oily and viſcid; in this caſe they contract the veſſels of the tendons on the hind part of the head and upper part of the neck, which are continually ſpewing out a matter or ichor that can hardly be digeſted, or the profuſion abated without ſuch applications as theſe.

POND, a reſervoir or receptacle for collecting and preſerving water.

The neceſſity of water, in all paſtures, is ſelf-evident; as cattle cannot live without it, and the driving of them far for it is known to be prejudicial to their health, in hot weather, beſides being attended with great trouble, and a conſiderable loſs of time. This is ſo ſenſibly felt in many parts of England, that people are obliged to dig wells, even to ſuch a deph as, frequently, to require the aſſiſtance of a horſe to draw up the water. The means of rendering it eaſily come at, muſt therefore enhance the value of the land where it can be ſo procured, and are of very eſſential conſequence to the huſbandman.

Where the ſurface of the ground is ſand or gravel, there ſeldom is occaſion to dig deep for water; becauſe ſuch ſoils generally lie upon marle, or ſome other rich earth, through which the water cannot deſcend. Beds of clay are moſt commonly thicker than thoſe of ſand or gravel; and chalk is, too often, the thickeſt of all. But wherever water is wanting, the farmer ſhould bore through the incumbent earth, if he intends to fit his land for paſture; and if he finds the expence of obtaining it too great, his beſt way will be to convert the ground ſo circumſtanced into arable, or to plant it with timber-trees ſuited to the nature of the ſoil.

Wherever water ſtagnates in a ſandy or gravelly ſoil, the huſbandman ſees at once at what depth is the ſurface of

of the earth which retains it. But in other ſoils, and when this does not happen, Palladius, and the authors of the *Maiſon Ruſtique*, give the following directions how to ſeek for water, with the greateſt probability of ſucceſs.

Where ruſhes, reeds, flags, willows, and other aquatic plants grow ſpontaneouſly, or where frogs are obſerved to lie ſquatted down cloſe to the ground, in order to receive its moiſture, there generally is water underneath. Perſons who make it their buſineſs to find out ſprings for fountains, caſcades, &c. look upon it as an infallible ſign of ſubterranean water, when they ſee a vapour ariſe frequently from the ſame ſpot of ground. Others aſſure, that wherever ſwarms of little flies are ſeen conſtantly flying in the ſame place, and near to the ground, in the morning, after ſun-riſe, there certainly is water under that ſpot. Again, where water is wanted on land apparently dry, let a man before ſun-riſe, lie down flat upon his belly, reſting his chin upon his fiſt placed cloſe to the ground, that his view may be directed quite horizontally, and not riſe too high, and in that ſituation let him look ſtedfaſtly toward the eaſt. If he then ſees a tremulous vapour ariſe from any particular ſpot, let him mark the place, by noticing ſome neighbouring tree, ſhrub, or other indication, and he will find water underneath it. But this experiment is to be made only on ground whoſe ſurface is dry; becauſe other exhalations, from a damp ſurface, would be apt in this caſe, to miſlead the inquirer.

Another way is thus. Dig a hole three feet wide, and at leaſt five feet deep, and place at the bottom of it, when the ſun is about to ſet, a pan, or baſon, rubbed with oil on the inſide: let the bottom of this veſſel be uppermoſt; cover it with dry hay, fern, or ruſhes, and over that with earth, and if any drops of water are found ſtanding on its inſide the next day, a ſpring is probably not far off. Or, put a new, unbaked, but well dried, earthen veſſel into ſuch a hole, and cover it as before; and if there be water in that place, this veſſel will be found ſoft and wet the next day. Likewiſe if wool be left all night in a trench of this kind, and water can be ſqueezed out of it the next day, little doubt remains but that of plenty of water may be met with there.

The month of Auguſt is generally looked upon as the moſt proper time to ſearch for water; becauſe, we apprehend, as the heat of the preceding ſummer will have warmed the earth to a conſiderable depth, any ſteam ariſing from water reſting on an impervious ſoil underneath, and particularly in hollows on the ſurface of that impervious ſoil, will then be moſt exhaled by this warmth. Now it is this ſteam, or vapour, which produces the before-mentioned ſigns.

By whatever method water is found, the means of coming eaſily at it are the next conſideration. If it be on a plain, there is no other way than digging a well. In doing this, the ſubſtance under the ſand or light ſoil muſt be dug into, to form a reſervoir of water for occaſional wants; and this reſervoir ſhould be made deep and large, in proportion to the quantity wanted. If there were no ſuch reſervoir, the water, after having riſen a little above the impervious body underneath, would glide along its ſurface, as uſual, and very little of it could then be obtained, either by pumps, buckets, or any other way employed to raiſe it. If the well is made in a ſloping ground, and the declivity is ſufficient to give it an horizontal vent, it will be worth the huſbandman's while to dig ſuch a paſſage, and, by means of pipes, or any other conveyance, to carry the water acroſs the light ſoil, through which it would orherwiſe ſink. The greateſt quantity of water will be obtained in this manner, becauſe there will then be a continual ſtream.

If the ſoil is very deep, and its ſurface has inequalities in which rain water runs in any quantity; this may be collected in ponds made in the loweſt parts of ſuch grounds.

If a body of clay is found near the ſurface, it is worth the farmers while to bore, that he may know at what depth a bed of ſand or gravel may be met with: for he will be ſure to find plenty of water in this laſt. If this be in a declivity, he need only cut an horizontal paſſage, and the water will flow ſo freely as even to double the value of his land.

Here again the farmer needs not ever to be at a loſs, becauſe it cannot be very difficult to make a pond in a clayey ſoil, which is, of itſelf, retentive of water. But it may, perhaps, be adviſable, even in this, to cover the bottom of the pond with a coat of gravel, in order to prevent its being poached by cattle, whoſe feet would otherwiſe be apt to ſink deep into the clay. Some farmers judiciouſly pave the declivity by which the cattle enter into the pond, and this renders it much more laſting than it would otherwiſe be, and preſerves the water clean.

When ponds are made in a looſe ſoil, much more care is neceſſary. The bottom and ſides there muſt be covered with a thick coat of the toughеſt clay, from a foot to two feet thick, well rammed down. Some have added hair and loam to the outer part of this covering, with a view of rendering it leſs liable to chap: but a thick coat of gravel is more neceſſary here, that the feet of the cattle may not pierce through the clay. Perhaps the expence of paving the whole inſide of a pond, might, in the end, be money well laid out.

The greateſt difficulty of finding water is in chalky ſoils, becauſe theſe are not, of themſelves, very retentive of it, and generally lie in ſuch thick beds, that it is expenſive to dig through them. However, it ſhould be tried; and if ſand or gravel be found underneath, water may be depended on. Even here, ponds are eaſily made, by digging into the chalk, and lining them with a coat of clay, as before directed. If there is a ſupply of proper manure, ſuch as clay, or marle, this ſituation is well adapted to grain, which loves to ſtand dry; and as this kind of ground produces more forward crops than clayey or ſtrong ſoils, it may be ſowed early with corn, which will not, in that caſe, be ſo apt to be parched up as graſs is, by the ſummer's drought. If a good ſoil can be made here, a foot deep, it will yield plenty of various ſorts of paſture, either roots or graſſes, as the farmer ſhall judge moſt proper: or it may be planted with different kinds of timber-trees. For the method of making ponds in gardens, *ſee the article* GARDEN.

POPLAR, a genus of trees, of which botaniſts enumerate four ſpecies; viz. the common white poplar, with large leaves: the common white poplar, with ſmaller leaves: the common black poplar, and the poplar with trembling leaves, called the aſpen tree. The poplar, whether black or white, may be eaſily propagated, either by layers, cuttings, or ſuckers, of which the white kind always produces a great many from the roots. The beſt ſeaſon for the tranſplanting theſe ſuckers is in October, when the leaves begin to decay; and they ſhould be removed into a nurſery for two or three years, at the end of which time they

they will have got ſtrength enough to be tranſplanted into the places where they are to remain.

When they are to be propagated by cuttings, it is beſt to do that in February, cutting off large truncheons of eight or ten feet long; which, being thruſt down a foot deep in the ground, will take root very quickly, and, if the ſoil be moiſt, will grow to a conſiderable ſize in a few years.

The black poplar is not ſo eaſily raiſed from theſe large truncheons, but ſhould be planted in cuttings, of about a foot and a half long, planting them a foot deep in the ground. This will grow on almoſt any ſoil, but does much better on a moiſt one than on any other. They are the fitteſt of all trees for raiſing a ſhade quickly, as they will grow fourteen feet in height ſometimes in one ſeaſon, and in four or five years will be large trees.

A conſiderable advantage may be obtained by planting theſe trees upon moiſt boggy ſoils, where few other trees will thrive: many ſuch places there are in England, which do not, at preſent, bring in much money to their owners; whereas, if they were planted with theſe trees, they would, in a very few years, over-purchaſe the ground, clear of all expence: but there are many perſons in England, who think nothing, except corn, worth cultivating: or, if they plant timber, it muſt be oak, aſh, or elm; and, if their land be not proper for either of theſe, it is deemed little worth; whereas, if the nature of the ſoil was examined, and proper ſorts of plants adapted to it, there might be a very great advantage made of ſeveral large tracts of lands, which at this time lie neglected.

The wood of theſe trees, eſpecially of the white, is very good to lay for floors, where it will laſt many years; and, for its exceeding whiteneſs, is, by many perſons, preferred to oak; but, being of a ſoft contexture, is very ſubject to take the impreſſion of nails, &c. which renders it leſs proper for this purpoſe: it is alſo very proper for wainſcotting of rooms, being leſs ſubject to ſwell or ſhrink, than moſt other ſorts of wood: but for turnery-ware, there is no wood equal to this for its exceeding whiteneſs, ſo that trays, bowls, and many other utenſils, are made of it; and the bellows-makers prefer it for their uſe; as do alſo the ſhoemakers, not only for heels, but alſo for the ſoles of ſhoes: it is alſo very good to make light carts; the poles are very proper to ſupport vines, hops, &c. and the lopping will afford good fuel, which in many countries, is much wanted, *Miller's Gard. Dict.*

Red POPPY, or *Red-weed.* The common wild red poppy is one of the moſt miſchievous weeds the farmers are plagued with among their corn, and it is the moſt difficult to thoroughly deſtroy of almoſt any other. Its ſeed will lie a long time in land unploughed, without ever ſhooting; but they will be ſure to grow with every crop of corn. Mr. Tull gives an inſtance of the ſeeds of this plant being buried four and twenty years in a field of ſainfoin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, though they had lain dormant ſo long before. *Tull's Horſe-hoeing Huſbandry.*

POTATOE, or POTATO, the name of a well known plant, the roots of which make a very nouriſhing food.

Mr. Houghton deſcribes the potato to be a bacciferous herb, with eſculent roots, bearing winged leaves and a belled flower; and ſays, that, according to his information, which is allowed to be very right in this reſpect, it was firſt brought from Virginia, by Sir Walter Raleigh, who, ſtopping at Ireland, about the year 1623, gave away a number of theſe roots, which were planted there, and multiplied ſo exceeding, that, in the wars which happened afterwards in that country, when all the corn above ground was deſtroyed, potatoes became the chief ſupport of the people: for the ſoldiers, unleſs they had dug up all the ground where they grew, and almoſt ſifted it, could not have extirpated them. The Philoſophical Tranſactions obſerve likewiſe, that the Iriſh were relieved from their laſt ſevere famine, which laſted two years, during which all their corn failed, merely by the help of this root. From Ireland it was brought to Lancaſhire, now famous for its potatoes: and the culture of this plant has, within theſe laſt thirty years, been extended to almoſt every part of England. The rich, who, at firſt, deemed them fit for none but the meaner ſort of people, now eſteem them ſo much, that Mr. Miller thinks the quantity of them which is cultivated around London only, exceeds that of any other part of Europe.

The red rooted potatoes have purpliſh flowers, and the white rooted (for Mr. Miller diſtinguiſhes only theſe two general varieties) bear white flowers.

The potatoe ſeldom perfects its ſeeds in England; and if it did, the raiſing of it from them would be much more tedious and uncertain than propagating it by its roots, as is the general and right method: for theſe multiply exceedingly, and may be made to yield vaſt crops, with little coſt or labour.

"The Iriſh huſbandman, ſays Mr. Switzer, after blaming the Engliſh for planting this root uncut, becauſe it often contains five or ſix eyes, or perhaps more, from which the produce of the enſuing year is to ſpring; and alſo for not allowing that bulb, or rather the great number of ſhoots and bulbs that proceed from it, a ſpace of earth ſufficient for their nouriſhment, which is the reaſon why ſo many poor, ſtinted, unſerviceable potatoes are dug up in the autumn, relates the practice of his country, which is to chuſe middle ſized roots, for the largeſt are generally eaten, to ſingle out the eyes that ſeem ſtrongeſt and moſt vigorous, and to cut them out in ſquares of at leaſt half an inch every way: ſo that one root will ſometimes furniſh three or four good pieces to ſet.

"The ground, prepared for planting, is marked out for beds four or five feet wide, with intermediate alleys of two or three feet. It is then trenched, only a ſingle ſpit deep, and the bottom of this trench, made as in common garden-trenching, is covered with dung, long and ſhort, taken out of a wheel-barrow which ſtands at the labourer's elbow. The potatoe-eyes cut as before directed, are placed upon this dung, at about five or ſix inches aſunder; and this trench is filled up with the mould taken out of the next, which is marked by a line at the diſtance of two or three feet. This trench is again filled with the mould of the next, and ſo on to the laſt, which is filled from the alley.

"The uſe of the dung thus laid at the bottom of the trenches, is not only to make the roots grow ſingle, for not above one root, or at moſt two, will in this caſe be produced by each eye, and theſe will be large and well fed; but it is attended with the farther advantage of making the potatoes run, and ſpread themſelves to a certain determinate depth, which is no ſmall help to their growing large.

"The laſt thing to be done to them is, in April or May (for they are planted in February or March) as ſoon as they begin to riſe, to dig the earth out of the alleys, as is done

done for aſparagus, and to cover the potatoe bed with it, about five or ſix inches thick. This will give new life and vigour to the roots, will keep the green from running too much to haulm, and will make the bulbs grow much the larger. By this means the crop of fine large potatoes will be almoſt the double of what is obtained when they are planted promiſcuouſly in the common way: nor will any farther culture be requiſite till they are fit to be dug up; except the pulling out of ſome of the largeſt weeds."

Mr. Miller's reaſons for diſapproving of the planting, either of the ſmall offsets entire, or the eyes cut out of larger roots, are, that though the former generally produce a greater number of roots, theſe roots are always ſmall; and that the cuttings of the larger roots are apt to rot, eſpecially if wet weather happens ſoon after they are planted. He therefore recommends, to make choice of the faireſt roots for ſetting, and to allow them a larger ſpace of ground, both between the rows, and between the plants in the rows; and he aſſures us that he has obſerved, when this method has been followed, that the roots, in general, have been large the following autumn. M. Duhamel, in his Elements of Agriculture, does not object at all to the planting of the cuttings.

The ſoil in which this plant thrives beſt, is a light ſandy loam, neither too dry nor over moiſt, but brought to a fine tilth, and ploughed very deep: for the deeper the earth is looſened, the finer and larger the roots will grow. In the ſpring, juſt before the laſt ploughing (according to Mr. Miller's method) a good quantity of rotten dung ſhould be ſpread on the ground, and this ſhould be ploughed in early in March, if the ſeaſon be mild; otherwiſe it had better be deferred until the middle or latter end of that month; for if a hard froſt ſhould come on ſoon after the roots are planted, they may be greatly injured, if not deſtroyed, thereby; but if they can be planted in the ſpring, without that danger, the better it will be.

The laſt ploughing ſhould lay the ground even, and then furrows ſhould be drawn three feet aſunder, and ſeven or eight inches deep. The roots ſhould be laid at the bottom of theſe furrows, about a foot and a half aſunder, and they ſhould then be covered in with earth.

After all the ground intended for potatoes is planted in this manner, it muſt remain in the ſame ſtate till near the time when the ſhoots are expected to appear; then it ſhould be well harrowed both ways, as well to looſen the ſurface and render it ſmooth, as to tear up the young weeds which will have begun to grow by that time. If much wet has fallen after the planting, it may have caked the ſurface of the earth, ſo as to retard the ſprouting of the plants; and this harrowing will, in ſuch caſe, almoſt anſwer the intent of a firſt hoeing.

I have placed the rows of potatoes at three feet diſtance, continues Mr. Miller, in order to introduce the hoe-plough between them; becauſe that will greatly improve their roots: for by twice ſtirring and breaking of the ground between theſe plants, not only weeds will be deſtroyed, but the ſoil will be ſo looſened, that every ſhower of rain will penetrate to the roots, and greatly quicken their growth. But theſe operations ſhould be performed early in the ſeaſon, before the ſtems or branches of the plants begin to fall and trail upon the ground: for after that, it cannot be done without injuring the ſhoots.

If theſe hoe ploughings are carefully performed, they will prevent the growth of weeds, till the haulm of the plants cover the ground; and after that there will be little danger of their growing ſo as to injure the crop; for the haulm will keep them under: but as the horſe-hoe can only go between the rows, it will be neceſſary to make uſe of a hand-hoe to ſtir the ground, and deſtroy the weeds in the rows, between the plants. If this is well done, in dry weather, immediately after each of the two horſe-hoeings, it will be ſufficient to keep the ground clean until the potatoes are fit to be taken up; which will be, very ſoon after the firſt froſt in the autumn has killed the haulm. They ſhould not remain much longer in the earth, leſt the roots themſelves be froſt-bitten, which ſpoils them. A four or five pronged fork is better to dig them up with, than a ſpade, becauſe it is leſs apt to cut them: but a principal thing to be conſidered here, is the clearing of the ground thoroughly of them: for if any are left, they will ſhoot up among the next crop, whatever it be, and do conſiderable damage, eſpecially if it be wheat, as is generally the caſe, ſown in the common broad-caſt way.

The beſt way of keeping theſe roots during the winter, is to lay them up in a dry place in very dry ſand, or in fine and perfectly dry earth.

The method of laying dung only at the bottom of the furrows in which the roots are planted, "is a very poor one, ſays Mr. Miller, becauſe, where the potatoes begin to puſh out their roots, they are ſoon extended beyond the width of theſe furrows, and the new roots are commonly formed at a diſtance from the old: ſo will be out of the reach of this dung, and conſequently will receive little benefit from it." But rather the contrary would ſeem to be the caſe, according to the Iriſh huſbandman, who, ſeem to ſpeak from experience, when he ſays, he had intended expreſsly to anſwer this very objection, that "the dung is placed at the bottom of the furrows on purpoſe to make the roots grow ſingle; and that its being ſo placed is attended with the farther conveniency of making the potatoes run, and ſpread themſelves at a certain determinate depth, which is no ſmall help to their growing large." Facts muſt here determine which is right: as they alſo muſt in regard to ſome parts of what Mr. Miller adds in the following words. "As moſt farmers covet to have a crop of wheat after the potatoes are taken off the ground, ſo the land will not be ſo thoroughly dreſſed in every part, nor ſo proper for this crop, as when the dung is equally ſpread, and plowed in all over the land, nor will the crops of potatoes be ſo good. I have always obſerved, where this method of planting the potatoes has been practiſed, the land has produced a fine crop of wheat afterward, and there has ſcarce one ſhoot of the potatoe appeared among the wheat, which I attribute to the farmers planting only the largeſt roots: for when they have forked them out of the ground the following autumn, there have been ſix, eight, or ten large roots produced from each, and often many more, and ſcarce any very ſmall roots; whereas, in ſuch places where the ſmall roots have been planted, there has been a vaſt number of very ſmall roots produced, many of which were ſo ſmall, as not to be diſcovered when the roots were taken up; ſo have grown the following ſeaſon, and have greatly injured whatever crop was on the ground."

Will not a thorough plowing and good harrowing, after the crop of potatoes has been taken off the ground, intermix the dung laid in the furrows, and the contiguous earth moſt impregnated thereby, with the reſt of the ſoil; perhaps almoſt as well as if the dung had been ſpread equally over the whole field, at the very firſt? If it will,

the preſumption ſeems ſtrong in favour of the Iriſh method. For certain it is, that the land ought to be well plowed and harrowed after the potatoes are removed, before it is ſown with any other crop; unleſs the ſeed for that crop, which generally is wheat, be ſprinkled by hand between the rows, as they are dug up, and there covered with the earth then turned over. This is practiſed in ſome parts of France: but, as M. Duhamel obſerves, the grain is ſo apt to be diſtributed unequally in this method, that it is better to plow the ground, and ſow it, in the regular way.

If the farmer apprehends that his land has not been thoroughly cleared of the potatoes, and is therefore afraid of their damaging his enſuing crop, his beſt way will be to lay it up very rough againſt winter; becauſe the froſts of that ſeaſon are known to kill and rot all potatoes in the ground expoſed to them, and it will at the ſame time be thereby finely prepared for ſpring corn; eſpecially as it will have been well enriched by the haulm of the potatoes lying upon it.

Though potatoes delight moſt in a light ſandy loam, neither too dry, nor over moiſt, as was obſerved before; yet Mr. Maxwell ſays he has ſeen them thrive well on ground that ſeemed to be very bad; even in deep moſs, which could not bear horſes to plow it, but which is conſiderably bettered by them; and on coarſe heath, where they were ſucceeded by grain, without more dung than was laid on at firſt. Of ſo improving a nature are they, and ſo much is the land enriched by the rotting of their ſtalks among it, and the digging it gets in raiſing them.

Several experiments communicated to M. Duhamel concur to prove the extraordinary increaſe of potatoes cultivated with the horſe-hoe: but as this will always be the conſequence of the New Huſbandry, whenever it is properly uſed, I ſhall only borrow from him, on this occaſion, M. de Viller's account of his method of practice, becauſe it is the cleareſt and moſt conciſe.

"There are, ſays he, ſeveral ſorts of potatoes, That which I cultivate is the middle ſized. It is planted about the end of April, or the beginning of May, and it ripens in October. My beds are five feet wide. I give them two plowings in the ſpring; at the ſecond of which I half fill the main furrow. Before I plant, I cut a ſmall furrow with the ſingle cultivator, which likewiſe looſens the earth; but if it be moiſt, I put a double ſpring-tree bar to the cultivator, to avoid the poaching of the horſes. I then plant the potatoes a foot aſunder in the row; chooſing for this purpoſe ſuch as are about the ſize of a walnut. They are thruſt in by hand, two or three inches deep; and if the mould does not then cover them ſufficiently of its own accord, a little more is puſhed down upon them.

"A ſlight hand-hoeing can hardly be avoided afterwards, to deſtroy the weeds which ſpring up at the ſame time as the potatoes: but this hoeing need not extend farther than three or four inches on each ſide of the row; becauſe the plow will do the reſt.

"I give the firſt hoe-plowing in the ſpring, as for wheat; but earlier or later, according to the condition of the ground.

"My ſecond hoe-plowing is given as ſoon as the plants are tall enough to be earthed up; that is to ſay, when they are eight or ten inches high. I then turn the earth up towards them as much as poſſible.

"As this plant ſpreads greatly, and ſhoots out very faſt, it would be impoſſible to give more than two of theſe hoeings, if one ſhould neglect to take advantage of the time when its leaves and branches do not entirely cover the bed.

"The roots are dug up in October, or perhaps ſomewhat earlier or later, according to the ſeaſon, with a ſtrong iron prong; ſhaking and clearing them well from the mould. They are then left to dry for ſome hours, and are afterwards laid up in a place where the froſt cannot reach them.

"This fruit, which yields ſurpriſingly, is of great ſerſervice to feed and fatten cattle, eſpecially when it has been boiled a little. They like it very well raw, after it has been kept a few months above ground: but it is beſt for them after it has been boiled."

The reader is obliged to the ingenious Mr. Irwin for the following account of cultivating potatoes in Ireland, and which we ſhall give in his own words.

"The potato, ſays he, is become a root of ſuch immenſe utility, eſpecially to the poorer ſort, within this century, that too much, methinks, cannot be ſaid towards improving, and extending the culture of it.

"In Provence, Dauphiny, Switzerland, and ſeveral other parts of Europe, and even in America, it yields commodious, abundant relief to the more indigent, as being eaſily ard plenteouſly propagated in almoſt every kind of ſoil.

"In Ireland particularly it is the principal food of the poor during the greater part of the year, without which, ſince the late unproportionable riſe of lands in that kingdom, to the trade of it, they could not well ſubſiſt. And, indeed, it ſeems a particular favour of providence ſent to them on this account.

"In times, not very remote, lands were cheap there, and the peaſantry, conſequently, lived on nouriſhment ſomewhat more luxurious, diverſified: their labour alſo was leſs burthenſome. But now, being obliged to work hard at four-pence and ſix-pence a day, and their rents conſiderably augmented, it will not ſeem ſurpriſing that this root alone has become the ſtaple of their ſupport, and that they have been the firſt people in Europe, or, perhaps, in the world, that have led the example in an extenſive improvement of it. This may naturally be ſuppoſed to ariſe from cloſe-preſſing neceſſity, the moſt cogent and inſpiriting of all motives.

"In truth, with much reaſon; for a poor labourer, in that ill-fated country, is driven to ſeek his ſole refuge for ſubſiſtence in this root, for the inexorable impoſition of a hard-hearted landlord, (ſorry I am to have it to ſay, too many of them grind the poor; but hope it will not be long the caſe) who thinks he cannot get too much for his land out of the perſons, or purſes, of his dependents, and who hath ſo inverted the old cuſtoms, that a hewer of wood, and drawer of water, (and many of theſe perhaps deſcendants of former proprietors) can afford himſelf but a miſerable ſcanty platter of potatoes, ſeaſoned with a palatable grain of ſalt, and waſhed down with a draught from the next rivulet, to ſupport the fatigue of thirteen hours (ſtatute quantity) of unceaſing labour, about his ancient manſion-houſe, or in his elegant gardens, well-laid out cloſes, or refreſhing bog-holes.

"The potato is a root; a little of which is very filling, quickly appeaſing hunger; but by no means a laſting ſolid nouriſhment for a labourer, as evidently teſtify the ſqualid

ſqualid looks of numbers of the poorer Iriſh; though at the ſame time it is in general wholeſome, agreeing with moſt ſtomachs that can vary their food; but, like other productions of the earth, forbid in many caſes by the medicinal tribe.

" There are ſeveral ways of breeding potatoes in Ireland, which partly ariſes from the difference in ſoil, and kinds of ſeed. The different ſoils for this purpoſe in uſe in my neighbourhood, for about twenty years paſt, and which, I believe, are pretty general, are the following, wherein they are abundantly propagated, viz.

" Firſt, On rich clay land without any manure, vulgarly called graſs potatoes.

" When a leaſe is near being expired, that is, during the laſt ſeven years of it, if there be no covenants grounded on the ſtatute againſt waſte, &c. the tenant, finding no hopes of a renewal, ſets conſiderable tracts in this way, where the ſoil will admit of it.

" Secondly, On good ley land well gravelled, (otherwiſe ſanded) which ought to be done a year before planting. But the poorer ſort, who are the chief cultivators of this root, are obliged to ſand and plant at the ſame time, or nearly thereabouts; which is very deſtructive to themſelves, their potatoes not having the proper benefit of the manure; at leaſt one part in three of the return are on this account exceeding ſmall, and are from hence called poreens by them, being a diminutive expreſſion. Whole fields are ſet in this way, commonly called ſpaddane, in which a conſiderable trade is driven; eſpecially in the provinces of Munſter and Connaught.

" Had it been properly and moderately done, it would be a fine preparation for the encreaſe of corn, and the laying down and bringing in, or, in other terms, the reclaiming of land; but the poor do it ſo negligently, and mangle it ſo intolerably, having but a ſhort temporary uſe in it, beſides paying near double the worth for it, that this manufacture, which might otherwiſe be of conſiderable benefit to Ireland, is, as now carried on, rather the contrary.

" Thirdly, On ground previouſly gravelled (that is perhaps ſix months before) and dunged at ſetting time. There is but little done in this way, except by the gentry, and renters of land for their private uſe; it being as yet out of reach of the peaſantry, unleſs in a few inſtances.

" Fourthly, On the ley with dung alone. Marle is not in uſe in my neighbourhood, though there is plenty of it in ſeveral parts of it; therefore cannot yet inform you how it would do for the potatoes in that diſtrict. As to potatoes ſet in the ley with dung alone, this manufacture alſo is done, as you may judge, moſtly by the more opulent. I have, however, often ſeen large fields ſet in this way to the public; but it is not of late years ſo much the cuſtom, this ſort of land being commonly kept for grazing: this hurts the land; and any preparation out of the ley for potatoes will, if not previouſly gravelled.

" Fifthly, In a rable or ſtubble land, vulgarly called ſticking or thruſting of potatoes, becauſe they are ſown with a ſtick, pointed at the end, about an inch diameter and two feet long, with the loy (otherwiſe the Iriſh ſpade.) In this method dung is alſo uſed, which ſhall be noticed in loco.

" Theſe are the moſt general methods that now occur to me, or I believe that are in uſe. There are, however, ſome others ariſing from the quality of the ſeed, practiſed only by the curious, in which the plants are put down at nine or twelve inches aſunder every way, in little hillocks, (like the hop plant) as practiſed in ſeveral counties in England; and, if you land them at certain proper ſtated times while vegetation continues, you will have a handſome neſt of large oblong potatoes at every landing.

" I made the experiment of one ſort in my garden; and out of half a dozen potatoes cut into ſeveral pieces, each having an eye, I had, to the beſt of my remembrance, without exaggeration, a quantity nearly equal to twelve Wincheſter buſhels.

" This kind of potato is introduced into Ireland but of late years: it is however well known there.

" A potato entirely black is alſo in uſe in Fingal, near Dublin, fructifies abundantly, and eats exceeding dry, which principally marks the goodneſs of this root in almoſt every inſtance.

" There are ſeveral kinds of potatoes. Mr. Maxwell, of Arkland in Scotland, a very judicious gentleman, has particularly noticed ſix ſorts, viz. The long red, the round red; the long white, the round white, or Spaniſh potato; the blue, the leather-coat, and an early kind that comes in a month ſooner than the common ſort, though planted at the ſame time.

" This root being greatly manufactured in Ireland, they mix moſt of the better ſorts promiſcuouſly, both for uſe and ſeed.

" I remember, about twenty-five years ago, the large red potato; then called the Caſtonian, (perhaps from Caſtile) as alſo the oblong Spaniſh white potato, to be chiefly in uſe; but now a leſſer ſort, ſuch as the Munſter or kidney potato, of a whitiſh or lightiſh yellow colour, the leather-coat, or round red Cronian potato, with a rough thick ſkin, and particularly that ſtiled the Spaniſh white potato, are moſtly in uſe.

" All theſe ſorts are cut for ſeed, according to the number of eyes on them, and thrive generally well with very little care; ſo that all ſorts being now ſo plenty, and anſwering ſo well, there are (as we may eaſily judge) no over nice diſtinction made about them there. The poorer Iriſh, who affect not to plant this root in bottom lands, or wet ſwampy grounds, unleſs hard preſſed for ſoil, are even in this caſe ſeldom attentive about the kind of potato they put down, the return being commonly wet, unfit for eating, and only proper for ſeed, which (from my little experience) I think makes but indifferent, though ſown in the beſt prepared upland; for too much moiſture, as well as too much dung, makes a potato wet: and plant it when you will, I am apprehenſive it never loſes this quality, which is the worſt it can have, except being rotten, or froſt-bit: nor will any eat ſo well, raiſed from dung, as without.

" As the potato thrives in different ſoils, ſo there are different methods of cultivating it: I will therefore now proceed to that moſt generally in uſe in my neighbourhood, (and indeed all over the kingdom) called graſs potatoes or ſpaddane, and by ſome (improperly) conacres, which ſeems to be the natural culture, but doubtleſs not ſo good to make the land ſtand long proof, (notwithſtanding the graveling) as if artificial manures were added, ſuch as dung, compoſt, lime, &c. for marle, lime-ſtone, gravel, ſea-ſand, ſhells, &c. I conſider in the claſs of natural manures and the beſt; and providence hath kindly given them in every ſpot, (even in the unpromiſing deſerts of Zara, &c.) had we known how to come at them.

" Land in the ley, (as I ſaid before) and that which requires no manure, the Iriſh ſeek moſt greedily after; ſome of which has not been ploughed perhaps within this century: ſo that you can only juſt diſtinguiſh that it has been tilled, and the tilth generally curved, the old people inclining the plough with the caſual ſhape of the field, ſo as to let the water in the furrow have a drip or fall.

" When a peaſant has the good luck to get a bit of ſuch choice ground, (for two or three of them will be concerned in an acre, and few take more than one) he follows the old ridge with his loy, or Iriſh ſpade, unleſs compelled by the poſſeſſor of the land to make his ridges ſtrait, which he moſt unwillingly does, and at beſt but aukwardly, with a rope made of hay or ſtraw, or ſome of his wife's worſt tow; neither of which ſtretching right, and often breaking, ſeldom admit well-looking ridges: theſe he makes from one end of his ground to the other, the beds being about three, or at moſt four feet wide, and the furrows, or trenches, about two. When he depoſits the ſeed on his bed, at about four or ſix inches at moſt aſunder, he divides the turf of his furrow in two equal parts, which he turns alternately in ſods on the edge or verge of each bed, the green ſide on the potatoes, cutting the ſods on three ſides or angles, leaving that next the bed uncut. This laborious work the poor fellow does ſurprizingly quick: two more men follow him, one digging the under ſtratum, and throwing up on the middle of the bed as much of the earth as he conveniently can with his loy: the remainder the third man caſts on with his ſhovel, ſettling the bed in the form, or manner, in which it is to remain.

" Some cover their potatoes at firſt (thro' want of time) with only the ſod, and about four or five inches of earth, and finiſh them perhaps, that is, caſt the laſt covering on them, not for a month, or ſix weeks after; which poſſibly may greatly check their growth. Many account this the beſt way, and it is become common; but I attribute the neglect of not finiſhing their potatoes, (as the term is) in due time, to no want of proper knowledge in the common Iriſh, but their inability to give the proper attention to their own little affairs, occaſioned by the greedy ſeverity of their maſters, as before obſerved.

" Others there are (and many) who, making the furrows unproportionably narrow to the beds, throw up a third ſpit or ſtratum, and perhaps not until two months after the firſt ſetting.

" This pernicious method may poſſibly deſtroy, or check the weeds; but certain I am, it will not contribute to the increaſe or largeneſs of the root, in the unphyſical or over heavy manner in which I have ſeen it done; becauſe this lower ſtratum, which is moſtly ſand, remains on the top of the richeſt part of the ſoil, and being thus unmixed with it, prevents it from receiving the proper benefits of the air, &c. beſides, too great a covering on the potato is highly prejudicial to it.

" In other caſes, theſe ſtratums thrown up, and mixed into a good tilth, would anſwer wonderfully, mixing well, being the life of good tillage. I would therefore in this place recommend to our farmers (who are too penurious of their land) to make their potato trenches ſo wide, as not to require throwing up much of the third or ſandy ſtratum on the laſt covering, or landing, of their potatoes: and they will find a much greater return, and one half (or more) leſs of poreens, or ſmall potatoes: which is an object highly worthy of their notice. The experiments I have made, I purpoſe repeating on my return to Ireland, and hope to prove this ſimple method to exceed that in the hillock, or in the drill way.

" In this manner all ley land is ſown with potatoes by the common people, and moſt others, whether manured or not. If dunged, the dung is laid out as the ridges are to be, but the ſand is ſpread all over the ſurface. Commonly little boys and girls precede the ſetters on the ridges, laying down the ſeedlings or potato eyes, which they do very quick, and tolerably well, at the appointed diſtance. This ſeems a giddy part of their buſineſs, and well ſuited to their years; but cuſtom makes them perfect in it.

" The next general method is planting potatoes in ſtubble ground, which is, in the common way above-mentioned, by dunging it well, and ſometimes by ploughing it in, and then ſhovelling up the ridges, a man going before lightly digging them, that there may be a ſufficient quantity of mould to cover them; but this the poorer ſort cannot well compaſs to do, and always avoid it when they can get a freſh or ley ſurface.

" Nor do they ſow them to chuſe, the ſecond year, in the ſame ground, without dung or ſome other artificial manure, (for the natural, ſuch as ſand, marle, &c. would not do) unleſs it be exceeding good.

" Lime, indeed, in this caſe will very probably anſwer, but it is rarely tried.

" There is alſo a cuſtom a good deal in uſe, which is by ſticking or thruſting potatoes in ſtubble land freſh ploughed, which is done in this manner: a man (but ſeldom two) goes on the crown of a narrow ploughed ſet, and ſticks his loy, or Iriſh ſpade, in it, every here and there, with his right foot, holding it in his left hand, and with it puſhing the ſpade once, and ſometimes twice from him, to make an opening, (which I have ſeen done with a great deal of dexterity) and with the right hand, that contains the ſeed, (a convenient quantity of which he carries in an apron, or cloth, tied round his middle, ſo as to let the contents be eaſily come at) he throws one, and ſometimes two ſets, or eyes, into the opening which the loy makes behind; and on his drawing it away, the looſened earth falls in and covers them. Soon after he dungs the ridges, and covers them up, as in the preceding method, with mould out of the furrows.

" Sometimes alſo they do this work with a ſtick about eighteen inches long, and an inch or ſo diameter, pointed at one end, and ſomewhat curved at the other. By this eaſy means huſband, wife, children, and ſervants, (if they have any) and a friendly neighbour or two, (who may be helped in return) aſſiſt at it for greater expedition, eſpecially when the ſeaſon happens to be advanced.

" In Scotland they do this work ſomewhat differently.

" In Ireland alſo there are many, who ſow potatoes after the plough, the ploughman letting the ſets drop in as he goes along; and a harrow matched to the ſame plough, following him cloſe behind, covers them in. There is no great difficulty in this, the land being in tilth. Over all they put dung; but they ſhould mind to give it a light covering, that the ſubſtance of it might impregnate with the adjacent earth, which it would not do, but evaporate by being left expoſed to the air, &c. yet this precaution many are very negligent in.

" The other methods, as in the drill, or hillock, or horſe-hoeing way, &c. are little uſed there, except among the more curious; but they being well known in England it is needleſs to mention them in this place.

" The next thing requiſite is the fencing, which ſhould be done, at fartheſt, before the ſtalk begins to appear; for, if

if the cattle, that are in that ſeaſon greedy for freſh vegetables, get at them, the roots of ſuch as they nip will never come to the ſize they otherwiſe would.

" This is well known in Ireland; and yet the poor, chiefly I believe from inability, and partly from a ſort of careleſſneſs, or rather lazineſs, they ſtill inherit (notwithſtanding the mixture of Engliſh and Norman blood, &c.) from their Spaniſh anceſtors, are very remiſs in this reſpect; eſpecially in the chiltern, or more fertile parts of the country; where, in moſt matters of huſbandry, they leave too much to chance, relying on the bounty of the ſoil.

" About me, and in many other parts, they very commonly do not put on the firſt covering till about the middle of May; and the ſecond, perhaps, not for a month after; ſo that it is often July before they fence them properly: and where many of them are concerned in a plantation (as is uſually the way) it is moſt troubleſome and difficult to get each man to do his part of ditching, which commonly is but a ſorry mound of ſods, with ſome buſhes ſodded down on top, to keep out ſheep, that ſmell this plant when it riſes (as cattle do corn) and are very dexterous in getting at it.

" Some of theſe poor people are ſo heedleſs, they never can be brought to make their fences; and then the owner of the ground, in his own defence, is obliged to get it done at an advanced price, and they to pay for it, or their potatoes to remain.

" Many of them, eſpecially in cheap years, leave them on the landlord's hands; and, unleſs a farmer collects himſelf, or has a good ſervant to do it, the rent is not had without immenſe trouble, and ſome of it never. Notwithſtanding theſe difficulties, many farmers have made eaſy fortunes in this way.

" Thus it happens, at the time they are often finiſhing the fencing, they ought to be weeding their potatoes. The weed that moſtly annoys them is the Scotch thiſtle: this ſhould be cut away in June, and if the ſoil ſhould be ſo rich as to require a ſecond weeding (which is very often the caſe) it ſhould be done in Auguſt. There will be no other trouble with them till digging time.

" The beſt time for this work is in the latter end of October, or beginning of November, to avoid the early froſts, which are mortal to them: but if, by bad huſbandry, they have been planted late, they ſhould be left longer in the ground, and covered with litter, or haulm, to prevent being loſt in this way.

" About Michaelmas the cattle are let through them, the roots not being then affected by the nipping, or beating down, of the ſtalk; this the peaſants know by the colour of it, which becomes a dark brown, loſing its verdure; as alſo by the apple and root.

" The more needy begin to dig them for uſe in Auguſt, though they are not then near ſo long in ground as they are in England; which demonſtrates the excellence and ſtrength of the Iriſh ſoil.

" When gentlemen farmers dig their potatoes, they ſet on a great number of hands at once, two to a ridge: boys and girls gather them promiſcuouſly, big and little, into bags containing about two Wincheſter buſhels; and thus they are carried to the farm-houſe, and thrown into a room, in one heap, part of which is deſtroyed by the froſt, a great part by the kitchen, alſo by the hogs, who deſtroy them much while in ground, there being hardly any fencing againſt them; a great part are alſo ſtole by the followers, or hangers-on; and the remainder rarely ſuffices for ſeed, of ſo little value is this eſtimable root conſidered in thoſe parts: and yet I have often known them at a very high price, from ten to twenty ſhillings, and upwards, the big barrel, which is the uſual meaſure in the weſtern parts of Ireland; that is, above two barrels, or eight buſhels, Wincheſter meaſure.

" Had they ſuch places as Covent-Garden near them, the caſe would be far different: but where there are no convenient and briſk markets, the waſte in farms is always great.

" Though, as I remarked before, low or ſwampy grounds do not anſwer well for potatoes, yet they ſometimes thrive, and are large, the meat being generally ſcabby, cloſe, wet, and heavy, from the too great impregnation of the water, which renders them unpalatable, and not the beſt for ſeed; however, ſuch are chiefly uſed in this way: yet I have ſeen them planted in red bogs, which are the wetteſt and worſt; and the bog being previouſly ſanded and dunged, the ſtalk looked green and healthy, and ſome of the roots might perchance have eat dry; but thoſe planted in black, or drier bogs, have been found to ſucceed well.

" There is no culture perhaps, yet known, will better reclaim waſte and unprofitable lands, than that of the potato. Ireland can well prove the truth of this aſſertion in a numberleſs variety of inſtances.

" I have ſeen ſeveral tracts of woodland ſtubbed up, and brought into fine tilth, by means of the potato huſbandry. America, I believe, can ſay the ſame.

" Of late years the hard-hearted ſky-farmers, that is the inferior ſort, and even ſome of our gentlemen-farmers, drive the poor into the mountains, moory grounds, wooded and ſtony lands, and even into the bogs; and when, by the culture of the potato principally, they have reclaimed them, ſo as to be fit to admit cattle, they are turned out without ceremony. I have in ſuch places ſeen as fine crops of potatoes, and afterwards flax, and different kinds of corn, as I ever met with any where.

" The mountain and other ſurfaces, except bog, ſeldom fail being bleſſed by nature with lime-ſtone, gravel, (which is the commoneſt) or ſome other manure, adapted to them; ſo that it is nothing but hands, money, and a proper limitation of the grazing-farming, that are wanting to make almoſt the whole kingdom look like a garden, or like England; I need go no higher with the compariſon.

" It is true, in ſome few counties of Ireland, in particular diſtricts, nature either has not been ſo bountiful, or the farmers have not found out the internal manures; being obliged to carry ſea-ſand, and other ſorts, many miles; in which however they find their account, notwithſtanding the impolitically too much limited trade of the kingdom.

" Before I diſmiſs this ſubject, it may be proper to obſerve, that a ſecond crop of potatoes is ſometimes taken out of the ſame land ſucceſſively; but this is not common, at leaſt about me, though I believe the land is as good as any in the province. On the contrary, the uſual way is, after the firſt crop of potatoes is taken off, if the ſoil is ſtrong, they immediately ſow bere in it, or keep it till the following ſpring for flax, which requires an equally ſtrong ſoil: or if the ground be but of a midding good ſort, they ſow it, juſt after the potatoes are taken out, with wheat; or keep it till the April following for barley.

" The ſky-farmer generally takes the land into his own hands after the firſt crop of potatoes, and ſows it with

here, wheat, or barley, for two or three ſeaſons; after which, if he refreſhes it with a ſummer, or a winter fallow, he ſows the ſaid kinds of grain in it for two or three ſeaſons more; then he takes two or three crops of oats; and when it is well impoveriſhed, or drawn (as they call it there) he lets it for ſeveral years together, in con-acres, to the poor people, for at leaſt one third more than the real value.

"From hence we may judge how much an alteration of method in huſbandry is wanting in thoſe parts."

Mr. Irwin is certainly right in ſaying, that lime would very agreeably anſwer; for in the Iſle of Man, though they are no farmers, yet they cultivate exceeding fine potatoes, as they are their principal food.

Some bring in different ſorts of land by the means of them: in moory ground, after the heath is burnt off it, they mark out the beds, upon which they ſpread out the lime in near about the ſame quantity that is required in liming ground, or rather more; upon which they lay the ſeed in the uſual manner, and, after cutting the turf in the furrow, lay it on the verge of the bed with the heathy ſide undermoſt, and cover them over with the mould out of the furrow in the common method.

After coming up, they weed, or give them a ſlight covering, to keep down the weeds.

When they raiſe them, it takes a little more labour; yet while they are digging a crop of very fine dry potatoes, they are gaining a piece of ground, which was before uſeleſs, and making it fit for ploughing and bearing corn the year following.

Lime is found alſo to be of excellent ſervice to potatoes in cold ſour land, which they manage after the ſame manner, and reap potatoes greatly excelling thoſe without lime, on the ſame ground.

Lime is certainly a very fine manure for potatoes: they uſe it in the iſle above-mentioned, without any other thing, on all ſorts of land, even upon a light, rich, limeſtone ſoil; and it betters the quality of the potatoe ſurpriſingly: beſides fermenting and melioraiing the ſoil, it has the property of attracting and abſorbing any cold ſour matter which may be prejudicial to vegetation.

About Caſtletown, in the ſame iſle, they take a great deal of care in their culture of potatoes, and their product pays them very well for their trouble.

After marking out the bed with their ſpade, and ſpreading on the dung, or lime, they begin at one end, and dig acroſs the bed, making it a ſpadeful, all along, higher than the neighbouring ground.

Then they dig and caſt the mould out of the furrows upon the bed, in the common method; and after finiſhing it, they, with a kind of dibble, or ſhaft of a ſpade ſhod with iron, ſome round and ſharp, others ſquare, about three or four inches broad, plant in the ſeed, about ſix or more inches diſtance from one another; and when they come up above ground, they weed them as clean as a garden, and after they are ſtronger and higher, with a hoe earth up the mould about the ſtalks; by which they kill the weeds, and have exceeding fine potatoes.

PREGNANT, teeming, breeding, fruitful.

PRICKING, a term uſed by farriers, &c. to ſignify the driving a nail into the ſoft part of a horſe's foot.

If a lameneſs proceeds from pricking in ſhoeing, the foot ſhould be pared thin on the wound ſide; and after dreſſing with tar and turpentine, let it be ſtopped with two ounces of common turpentine, melted down with four of lard.

If the nail penetrates to the joint of the foot, where matter may be formed, and by its long continuance putrify, ſo as to erode the cartilages of the joint, the caſe is incurable.

If the nail has paſſed up to the nut-bone, it is incurable, becauſe this little bone cannot exfoliate; and becauſe the cartilaginous part of it is deſtroyed, as ſoon as injured.

If the nail has not paſſed to the tendon, the horſe will do well, without a neceſſity for drawing the ſole; but if the tendon is wounded, the ſole muſt be carefully drawn, becauſe a ſinovia and gleet is diſcharged.

When gravel is the cauſe, it for the moſt part follows the nail-holes, and if it gets to the quick, cannot return, unleſs it is ſcraped out; for the make of the hoof, which is ſpiral like an ear of corn, favours its aſcent, ſo that the gravel continues working upwards towards the coronet, and forms, what the farriers call a quittor-bone.

The nature of this diſorder points out the method of cure, which is to be as expeditious and careful as poſſible, in getting out the gravel: if it is found difficult to effect this, let the ſole or hoof be pared thin, and if neceſſary, the wound inlarged to the bottom, and then dreſſed up as uſual. Should the coffin-bone be affected, remember, always to bathe the hoof with viuegar, or repellers, in order to allay the heat and inflammation, which often happen on ſuch occaſions; and ſhould the pain and anguiſh affect the legs, treat them in the ſame manner, or charge the leg and paſtern with a mixture of wine lees and vinegar.

PRONG, an implement much uſed in huſbandry, conſiſting of two or three pieces of iron, inſerted into a handle, for taking up corn, ſtraw, dung, &c.

PRONG-*hoe*, a term uſed to expreſs an inſtrument uſed to hoe or break the ground near, and among the roots of plants.

The ordinary contrivance of the hoe in England is very bad, it being only made for ſcraping on the ſurface; but the great uſe of hoeing being to break and open the ground, beſides the killing the weeds, which the ancients, and many among us, have thought the only uſe of the hoe, this dull and blunt inſtrument is by no means calculated for the purpoſes it is to ſerve.

The prong-hoe conſiſts of two hooked points of ſix or ſeven inches long, and, when ſtruck into the ground, will ſtir and remove it the ſame depth as the plough does, and thus anſwer both the ends of cutting up the weeds and opening the land. The ancient Romans had an inſtrument of this kind, which they called the bidens; but they were afraid of its uſe in their fields and gardens, and only uſed it in their vineyards. The prong-hoe comes into excellent uſe, even in the horſe-hoeing huſbandry; in this the hoe-plough can only come within three or four inches of the rows of corn, turneps, and the like; but this inſtrument may be uſed afterwards, and with it the land may be raiſed and ſtirred, even to the very ſtalk of the plant. *Tull's Huſbandry.*

PROPAGATION, the continuance or diffuſion of ſucceſſive production.

The ingenious Mr. Barnes has given us the following method of propagating trees by the bud and branch.

"Every leaf, ſays he, upon the branch of a tree, or ſhrub, has uſually a young bud in its boſom; and it is certain each of theſe buds has in it the rudiment of a tree of the ſame kind: therefore it appeared reaſonable to think that

that every branch might afford as many new plants as there were leaves upon it; provided it were cut into ſo many pieces, and a proper dreſſing was found to prevent the raw ends of each piece from decay. The beſt mixture for this purpoſe, upon careful and repeated experience, I have found to be this.

" Melt together, in a large earthen veſſel, two pounds and a half of common pitch, and half a pound of turpentine. When they are melted, put in three quarters of an ounce of powder of aloes; ſtir them all together; and then ſet them on fire: when it has flamed a moment, cover it up cloſe, and it will go out: then melt it well, and fire it again in the ſame manner: this muſt be done three times. It muſt be in the open air, for it would fire a houſe; and there muſt be a cover for the veſſel ready. After it has burnt the laſt time, melt it again, and put in three ounces of yellow wax ſhred very thin, and ſix drachms of maſtich in powder. Let it all melt together till it is perfectly well mixed; then ſtrain it through a coarſe cloth in a pan, and ſet it by to cool.

" When this is to be uſed, a piece of it muſt be broke off, and ſet over a very gentle fire; it muſt ſtand till it is juſt ſoft enough to ſpread upon the part of the cutting where it is wanted; but it muſt not be very hot. It is the quality of this dreſſing, to keep out wet entirely: the part which is covered with it will never decay while there is any principle of life in the reſt; and, this being ſecured, nature will do the buſineſs of the growing.

" This I have found true in practice; and by repeated trials, in more kinds than one, I have found that I could raiſe from any piece of a branch as many good plants as there were leaves upon it."

PRUNIFEROUS *trees*, thoſe which bear a pretty large and fleſhy fruit, with a nucleus in the middle.

PUCKBALL, a ſpecies of muſhroom, full of duſt.

PUDDOCK, or PURROCK, a ſmall incloſure.

PULSE, a term applied to all leguminous plants, as tares, peaſe, &c.

All the ſpecies of pulſe afford great abundance of excellent manure, in the ſtate in which nature preſents them. The cuſtom of ploughing in green ſucculent plants, is very ancient. All the Roman writers commend it highly, and with much reaſon. Columella recommends particularly lupins, as a manure, which, if cut down and turned in while green, will have as good effect as the beſt and ſtrongeſt dunging whatever. They may be ſown upon poor land about the middle of September, and will enrich it greatly if ploughed in before they attain their full growth. In gravelly ſoils, they ſhould be cut down after they have put forth their ſecond flower; and in ſtrong lands, after the third. In the former of theſe grounds they are turned in while young and tender, that they may quickly rot; and in the latter, they are let ſtand till they grow ſtronger, that they may bare up the more ſolid and ſtiff clods of earth, and keep them the longer ſuſpended; by which means the air has freer acceſs to the ſoil, and theſe clods, being heated and dried with the ſummer ſuns, are the more eaſily opened, and reſolved into duſt. Thus ſays this judicious author, juſtly remarkable for his ſuperior ſkill in huſbandry. But Mr. Miller is of a contrary opinion.

The *Maiſon Ruſtique*, a work of very high repute, as is evident from the great number of editions it has gone through, ſtrongly and rightly recommends peaſe, beans, lupins, vetches, and other ſucculent plants, as excellent manures, eſpecially for ſandy ground. Theſe plants enrich the earth greatly if ploughed in, either green, or when in bloom. In ſtrong land they ſhould not be turned down till the pods begin to harden.

In Piedmont and other places where they fatten their land with this manure, lupins are ſown upon the fallow ground towards the end of June, immediately after the ſecond ploughing, ſo that they are ſtill green when the third ploughing is given, and the corn is ſown. Experience ſhews the huſbandmen in thoſe countries, that this method of uſing theſe plants for manure makes them ample amends for the loſs of the pulſe or fodder they might otherwiſe reap from them: but thoſe who do not like to loſe any thing, plough in the huſks after they have taken out the grain.

Dr. Liſter likewiſe recommends for the improvement of ſandy, light ground, or any clay well ſanded, all plants of the pulſe or pea kind, and particularly, " upon experience, the wood vetch, which, beſides its being perennial (at leaſt with reſpect to its roots) and its thriving even in woods and among buſhes in almoſt every country, has theſe farther qualifications, that it ſhoots out a thouſand roots far and wide, and ſpreads itſelf under ground like quick-graſs; whilſt it is ſo rampant above ground, that it will climb a fathom and a half upon meaſure, and preſerve itſelf in ſpite of weeds or drought. It may be ſet, as well as ſown, in furrows. For the former of theſe purpoſes the roots may be dug up in September, which is alſo the time for gathering the ripe ſeed. The growth of the plants will be greatly advanced by ſetting their roots; for the older they are, the ſtronger, more numerous, and fuller of buds their ſhoots will be. I ſowed in the latter end of March the ſeeds which I had gathered in September, and had that year a very great increaſe, the bed being thick covered over with graſs above two feet high: but it did not flower that year. I reckoned that one pea had put forth above thirty ſhoots in Auguſt of the firſt year. In the ſecond year, it flowered by the middle of June, and bore a wonderful crop, the roots being innumerable. I have obſerved this pea very common in all the mountains, as well as plains of England, where buſhes or hedges are. Both the pea and graſs are very ſweet, and very agreeable to cattle, as I have tried."

Buck wheat and vetches are the two plants moſt commonly ſown in England, for manure. The beſt time for ploughing them in, is when they are in bloom; being then in their moſt ſucculent ſtate. Some farmers turn down their ſecond crop of clover, to enrich the land for wheat in the autumn. This ſhould be done early enough to give the plants ſufficient time to putrefy thoroughly before the grain is ſowed: otherwiſe, it might prove prejudicial, by bringing on a heat which would hurt the corn.

The Reverend and ingenious Mr. Eliot, of New England, prefers millet to every other plant for green-dreſſing of land, on account of the cheapneſs of the ſeed, and the largeneſs of the ſtalks and leaves, which muſt afford a good coat to turn in when ploughed. An old farmer, who had long been in the practice of green-dreſſing, aſſured this gentleman, that he had increaſed the ſtrength of his land to a great degree, in a few years, by the following method. After his oats were harveſted, he added a little ſeed to the ſcattered grains, and then ploughed them in. Towards the end of September, he ploughed in the green oats, and ſowed rye; and the next ſummer, when the rye was well grown and full of ſap, he plough-

ed,

ed that in at the uſual ſowing ſeaſon, then ſowed wheat, and always had a large crop.

PURGING, the operation of evacuating the impurities of an animal body by ſtool.

Purging is often neceſſary in groſs full horſes, in ſome diſorders of the ſtomach, liver, &c. but ſhould be directed with caution. Before a purge is given to any horſe, it is neceſſary ſome preparation ſhould be made for it, in order to render the operation more ſafe and efficacious: thus a horſe that is full of fleſh ſhould firſt be bled, and at the ſame time have his diet lowered for a week, eſpecially thoſe that have been pampered for ſale; ſeveral maſhes of ſcalded bran ſhould alſo previouſly be given, in order to open the bowels, and unload them of any indurated excrement; which ſometimes proves an obſtacle to the working of the phyſic, by creating great ſickneſs and griping.

Let it be remembered, that a horſe is purged with difficulty; that the phyſic generally lies twenty-four hours in the guts before it works; and, that the tract of bowels it has to paſs through, is above thirty yards; and lying horizontally, conſequently reſinous and other improper drugs may, and often do, by their violent irritations, occaſion exceſſive gripings and cold ſweats, ſhave off the very mucus or lining of the guts, and bring on inflammations, which often terminate in mortifications, and death.

It is remarkable too, that the ſtomach and guts of a horſe are but thin, compared to ſome other animals of the ſame bulk, and therefore muſt be more liable to inflammation and irritation.

Horſes kept much in the ſtable, who have not the proper benefit of air and exerciſe, in proportion to their food, ſhould in ſpring have a mild purge or two, after a previous preparation by bleeding, lowering their diet, and ſcalded maſhes.

Horſes that fall off their ſtomach, whether it proceeds from too full feeding, or ingendering crudities and indigeſted matter, ſhould have a mild purge or two.

Horſes of a hot temperament, will not bear the common aloetic purges; their phyſic therefore ſhould be mild and cooling.

Purging is always found very beneficial in ſtubborn dry coughs; but mild mercurials joined with them, make them yet more efficacious.

Horſes that have thoſe ſorts of lameneſſes, that are ſaid to proceed from humours flying about (which are of the rheumatic kind, and in young horſes proceed from ſizy blood, and occaſion lameneſs in every limb) require frequent purging; and ſhould alſo have between whiles, medicines that attenuate and thin the fluids.

Horſes of a watry conſtitution, who are ſubject to ſwelled legs, that run a ſharp briny ichor, cannot have the cauſes removed any ways ſo effectually as by purging.

The firſt purge you give to a horſe ſhould be mild, in order to know his conſtitution.

It is a miſtaken notion, that if a proper prepared purge does not work to expectation, the horſe will be injured by it; for though it does not paſs by ſtool, its operation may be more efficacious, as an alterative to purify the blood, and it may paſs by urine, or other ſecretions.

Purging medicines are very ſucceſsfully given in ſmall quantities, mixed with others; and act then as alteratives.

If mercurial phyſick is given, care ſhould be taken that it be well prepared; and warmer cloathing, and greater circumſpection is then required.

Purges ſhould be given early in the morning upon an empty ſtomach; about three or four hours after the horſe has taken it, he ſhould have a feed of ſcalded bran; and a lock or two of hay may then be put in his rack. The ſame day give him two more maſhes; but ſhould he refuſe warm meat, he may be allowed raw bran.

All his water ſhould be milk warm, and have a handful of bran ſqueezed in it; but if he refuſes to drink white water, give it him without bran.

Early the next morning, give him another maſh; but if he refuſes to eat it, give him as much warm water as he will drink: let him be properly cloathed, and rode gently about. This ſhould be done two or three times a day, unleſs he purges violently, once or twice will then be ſufficient: at night give him a feed of oats mixed with bran.

During the working, a horſe ſhould drink plentifully; but, if he will not drink warm water, he muſt be indulged with cold, rather than not drink at all.

We ſhall here inſert ſome general forms of purges.

Take ſuccotrine aloes ten drams, jallap and ſalt of tartar each two drams, grated ginger one dram, oil of cloves thirty drops; and make them into a ball with ſyrup of buckthorn.

Or,

Take aloes and cream of tartar each one ounce, jallap two drams, cloves powdered one dram, ſyrup of buckthorn a ſufficient quantity.

Or,

The following, which has an eſtabliſhed character among ſportſmen.

Take aloes, from ten drams to an ounce and a half, myrrh and ginger powdered each half an ounce, ſaffron and oil of anniſeed each half a dram.

Mr. Gibſon recommends the following.

Take ſuccotrine aloes ten drams, myrrh finely powdered half an ounce, ſaffron and freſh jallap in powder, of each a dram, make them into a ſtiff ball with ſyrup of roſes, then add a ſmall ſpoonful of rectified oil of amber.

The ſuccotrine aloes ſhould always be preferred to the Barbadoes, or plantation aloes, though the latter may be given to robuſt ſtrong horſes, but even then ſhould always be prepared with the ſalt, or cream of tartar; which by opening its parts, prevents its adheſion to the coats of the ſtomach, and bowels; from whence horrid gripings, and even death itſelf has often enſued. This caution is well worth remarking, as many a horſe hath fell a ſacrifice to the neglect of it.

Half an ounce of Caſtile ſoap, to a horſe of a groſs conſtitution, may be added to any of the above; and the proportions may be increaſed for ſtrong horſes.

When mercurial phyſick is intended, give two drams of calomel over night, mixed up with half an ounce of diapente and a little honey, and the purging ball the next morning.

The following, when it can be afforded, is a very gentle and effectual purge, particularly for fine delicate horſes; and if prepared with the Indian rhubarb, will not be expenſive.

Take of the fineſt ſuccotrine aloes one ounce, rhubarb powdered half an ounce or ſix drams, ginger grated one dram; make into a ball, with ſyrup of roſes.

The following purging drink may be given with the utmoſt ſafety; it may be quickened, or made ſtronger, by adding an ounce more ſenna, or two drams of jallap.

Take ſenna two ounces, infuſe it in a pint of boiling water two hours, with three drams of ſalt of tartar; pour off, and diſſolve in it four ounces of glauber ſalts, and two or three of cream of tartar.

This laſt phyſic is cooling, eaſy, and quick in its operation; and greatly preferable in all inflammatory caſes to any other purge, as it paſſes into the blood, and operates alſo by urine.

When horſes loſe their appetites after purging, it is neceſſary to give them a warm ſtomach drink, made of an infuſion of chamomile flowers, anniſeeds and ſaffron: or the cordial ball may be given for that purpoſe.

Should the purging continue too long, give an ounce of diaſcordium in a pint of Port wine, and repeat it once in twelve hours, if the purging continues. Plenty of gum arabic water ſhould alſo be given, and in caſe of violent gripes, fat broth glyſters, or tripe liquor, ſhould be often thrown up, with an hundred drops of laudanum in each.

The arabic ſolution may be thus prepared.

Take of gum arabic and tragacanth of each four ounces, juniper berries and carraway ſeeds of each an ounce, cloves bruiſed half an ounce; ſimmer gently in a gallon of water, till the gums are diſſolved: give a quart at a time in half a pail of water; but if he will not take it freely this way, give it often in a horn.

When a purge does not work, but makes the horſe ſwell, and refuſe his food and water, which is ſometimes the effect of bad drugs, or catching cold, warm diureticks are the only remedy; of which the following are recommended.

Take a pint of white wine, nitre one ounce, mix with it a dram of camphor diſſolved in a little rectified ſpirit of wine; then add two drams of oil of juniper, and the ſame quantity of unrectified oil of amber, and four ounces of honey, or ſyrup of marſhmallows.

Or,

Take Venice turpentine one ounce, incorporate with the yolk of an egg; nitre one ounce, then add juniper berries, and freſh anniſeeds pounded, each half an ounce, unrectified oil of amber two drams; make into a ball with ſyrup of marſhmallows.

Q.

QUEEN-BEE, a name given by late writers to what uſed to be called the king-bee, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every ſwarm, and which is always treated with the greateſt reſpect by the reſt. *See the article* BEE.

This is, indeed, the parent of the ſwarm, and from the fœcundity of this one female, a whole hive is eaſily and ſoon repeopled.

It is to be obſerved, that the autumn and winter ſeaſons deſtroy a great number of the bees; ſo that a hive, which was full in the ſummer, is often found ſo thinly peopled before the end of winter, that the bees ſeem only a few inhabitants in a very large city: by Midſummer again this ſame hive ſhall, however, be found ſo well filled with inhabitants, that there ſhall be a neceſſity of ſending out a colony in the name of a new ſwarm, and yet the hive will remain as full as it can well hold. This increaſe might well appear very amazing, if all the remaining bees of the hive were ſuppoſed to be females, and to join in it; but how much more ſo when it muſt be acknowledged, that it is all owing to one female, and that this queen-bee, or mother-bee, alone, has given origin to ſuch an immenſe progeny?

The form of this bee, and there being only one ſuch in a hive, naturally led all who ſaw it into an opinion of ſomething

ſomething ſingular in its nature, and the antients determined that it muſt be the king over the reſt: they made it an abſolute monarch, and have ſuppoſed that all the buſineſs of the hive was done by its immediate orders; and that the ſeveral parties of bees allotted to work in the making the combs, in the filling their cells, in the ſtopping the crevices of the hives, and in carrying away the filth, &c. had all their ſeveral ſtations allotted them by this wiſe and provident monarch. This was giving great talents to the monarch-bee; but this was mere fancy, and it is plain, that if this creature rules, it is over a people who all perfectly well know their ſeveral buſineſs: but it rather appears, that there is no ſovereignty at all, but that this creature is reſpected in a very high degree by the reſt, as the common parent of the whole nation.

There were not wanting among the antients, however, ſome who believed this large bee to be a female, and theſe pretend that ſhe brought forth only females like herſelf, which ſucceeded her in her reign. They had a very different opinion as to the origin of the common bees, not ſuppoſing them generated of animal parents like themſelves, but produced out of corruption, and born of the fleſh of a bull or cow. Among the later writers this opinion, notwithſtanding the ſanction of the poet Virgil, has been laughed out of the world; yet it was long before the true origin of bees, even after this, was known. The author of the Female Monarchy, though well apprized of this great bee being of the female ſex, yet ſuppoſed that ſhe only produced young ones like herſelf; and pretended that the common bees copulated together for the production of other bees like themſelves: this, however, has been ſince found to be wholly erroneous, the female, or queen-bee, giving birth to all, and theſe common bees being of no ſex at all. Many of the authors who have not given into the idle opinion of the bees being bred of putrid fleſh, have yet given them an origin not leſs idle and ridiculous. They pretend that the bees are exempted from the pain of producing either eggs or young; and that the offspring are formed of the juices of flowers, the different kinds, as the drones, females, &c. owing their riſe to juices of different kinds. Theſe, and a number of other falſe notions, have been propagated in regard to bees; but their true origin could not well be found till we were in a condition to ſee what paſſes at certain times within the receſſes of the hive, which is done by the uſe of that excellent invention, the glaſs hive. By this, and by the help of diſſections, we may eaſily inform ourſelves perfectly of the true ſtate of the caſe. The parts of generation are the ſubjects of our enquiry for this purpoſe, and, though the bodies of theſe animals are ſo ſmall, theſe are uſually ſufficiently large to be diſtinguiſhed, often taking up more room in the abdomen than all the other parts together. Thus, if the large long-bodied bee be opened, the abdomen will be found to contain vaſt numbers of oblong bodies, which any one acquainted with inſects will eaſily diſtinguiſh to be eggs: vaſt numbers of theſe are large enough to be obſervable by the naked eye, but, when the aſſiſtance of glaſſes is called in, there are diſcerned a vaſt number of other ſmall eggs, which exceed all computation. It is eaſy to determine from this, that this creature, ſo long eſteemed a male, is in reality, a female, and is in condition to give birth to a very numerous poſterity.

In order to diſtinguiſh this, however, a proper time muſt be choſen for the diſſection, and the moſt proper of all is when the creature is juſt ready to depoſit her eggs. This is in the months of April and May, and the moſt certain time of all is when ſhe is in a hive where a new ſwarm have been received about ten days before: if ſhe be diſſected at other times, the eggs are leſs viſible; and, particularly in winter, there requires a good glaſs to ſhew the rudiments of them. This is a diſagreeable experiment, indeed, becauſe it is always the deſtruction of a future ſwarm; all the eggs we ſee in the diſſected female being what would have produced bees to labour for our benefit.

When the body of one of the drones is opened, there is found, inſtead of theſe vaſt numbers of eggs, a part ſeeming proper for a male organ of generation: and in the abdomen a number of veſſels running in ſeveral windings and contortions, and filled with a milky humour. Theſe ſeem deſtined for the important uſe of impregnating the eggs in the belly of the female, and it is very natural to determine from this that theſe are the males.

The common bees, when diſſected, at whatever time of the year never ſhew the leaſt marks of any ſex at all. The inteſtines of theſe bees are found at times to be more or leſs diſtended with honey, and with rough wax; but there are never diſcovered any eggs, nor any of the winding ſeminal veſſels, ſo that it is plain they have no ſhare in propagating the ſpecies: and the obſervation of the ſwarms from time to time, with the aſſiſtance of glaſs hives, gives proof to what the diſſections ſeem to make ſufficiently certain without this evidence.

The female bee reſides within the center of the hive, always living in one of the ſpaces between the combs; if ſhe occaſionally comes out to the ſurface, and is ſeen walking over the edge of a comb, ſhe is to be well obſerved at thoſe times; for her only buſineſs is the laying her eggs in ſome of the empty cells of that part of the comb, which done, ſhe always retires again.

In order to ſee the female, or mother bee, employed in this operation, we are to obſerve in the morning hours, between ſeven and ten, what paſſes in a glaſs-hive into which a ſwarm have been received a few days before. The ſpeed with which the common bees labour in making their combs on this occaſion is almoſt incredible, and they ſeem not only to labour to have cells to depoſit their honey in, but to know that the parent bee is at this time loaded with eggs for the production of a numerous progeny, and that ſhe has an immediate neceſſity of cells for the depoſiting them in. This neceſſity is ſo urgent, that ſhe is often forced to depoſit them in cells not yet finiſhed; though the bees labour ſo vigorouſly, that they often will erect a whole large comb in one day. If the hive be narrowly watched at theſe times in the morning hours, the female bee will be ſoon found employed in her work, and will be ſeen dropping her tail by turns into ſeveral cells every day. If the combs be examined a day or two after this, they will alſo be found to contain the eggs; one of theſe is placed in each cell, and appears in form of an oblong white body, fixed either to the ſolid angle of the baſe, or to one of the angles compoſed by the rhombs which form the triangular baſe of the cell, and is always attached in ſuch a manner, that it lies nearly in an horizontal poſition.

The flat glaſs hives are the moſt favourable for the making theſe obſervations, ſince in thoſe the combs are ſo narrow

narrow and ſo numerous, that the whole is taken in view at a time, from one ſide or the other; and there are always ſeveral combs to be made choice of for the operation; in the morning hours of April and May, the female mother-bee will be uſually ſeen walking very ſoberly over one or other of theſe combs, attended by a guard of about twenty of the common bees, all placing themſelves in ſuch a manner, that their faces are turned towards her, and all paying her the greateſt marks of homage and adoration. As ſhe walks along in this ſtate, ſhe examines every cell as ſhe paſſes over, and ſuch as ſhe finds yet empty, and fit for her purpoſe, ſhe reſts at: and, introducing the hinder part of her body at the top, plunges it ſo deep in that her tail touches the bottom. Then ſhe depoſits one egg and no more, and this is at that time covered with a glutinous matter, which faſtens it to the place where it is laid: from this cell the female paſſes to ſeveral others, where ſhe depoſits her eggs in the ſame manner.

Some authors who have written of the polity of bees, have repreſented the time of the female bee's laying her eggs as a ſeaſon of feſtivity and rejoicing in the hive; but this does not at all appear to be the caſe; the few bees which attend her on this occaſion ſeem the only ones that know any thing of the matter, and their behaviour ſavours more of homage and reſpect than of joy: they are continually ſtroking and bruſhing her clean with their legs and with their trunks, and offer her from their own mouths the fineſt honey, when ſhe has occaſion for food. The reſt are all employed in their proper offices, and the work of the hive goes on as uſual; and, indeed, it is well that it does ſo, for this time of rejoicing would be of very bad conſequence to the affairs of the hive, if carried on as ſuppoſed, ſince the female bee is thus employed, more or leſs, during the whole ſummer months.

When the female bee has laid ſix or ſeven eggs, ſhe always takes a time of reſpite or repoſe; and, during this time, the bees which form her levee are doubly buſy in their careſſes, ſome bruſhing her head and breaſt with their trunk, but ſeveral being always employed together to cleanſe the hinder rings of the body, which have been fouled by being thruſt into the cells. When this is done, ſhe begins again; but Mr. Reaumur obſerves, that he never could ſee a female lay more than ten or twelve eggs at one time: he ſuppoſes that his preſence diſturbed the creature, and finally drove her into the inner parts of the hive, where ſhe might continue her works in cells leſs expoſed. It is not difficult to compute the number of eggs which the female lays every day, from the ſwarm which is ready to leave the hive at the end of May: this ſwarm uſually amounts to at leaſt twelve thouſand, and as the hive out of which theſe depart is not leſs peopled by their loſs, it is evident that they were all the produce of the eggs depoſited by the female in the preceding months of April, with a part of March, and a few of the firſt days of May. On a moderate computation, on theſe principles it will appear, that the female bee cannot lay leſs than two hundred eggs every day, for a long ſpace of time together; and this, though ſeemingly a monſtrous increaſe, is yet much leſs than that of ſome other of the winged inſects, in one of which, a two-winged fly, that author counted no leſs than twenty thouſand living worms, all ready to be depoſited by the parent, and to become flies of the ſame kind.

It has been ſtrongly objected againſt this ſyſtem, that, though the female bee lays eggs, ſhe is not the only one that lays; and many will not give up the opinion of the common bees alſo laying ſome eggs, though but a few in number; obſerving, that, if each of theſe lay only four or five eggs, it would be enough to give birth to a whole ſwarm, without ſuppoſing that this prodigious fœcundity belonged to the female bee alone: but this is running into the old error of the female producing only females like herſelf; whereas, if we obſerve the cells in which we ſee the female depoſit her eggs, we ſhall in the ſequel find the common bees produced from theſe eggs, and iſſuing out of theſe cells: this is a ſufficient proof to any fair reaſoner, ſince it appears very plain, that, if the female produces them, they do not produce one another. It is alſo evident, that not only theſe common or working bees, but alſo the drones, or male bees, are produced from the eggs of this ſame female; and there is this remarkable forecaſt in the female, that ſhe always depoſits the eggs which are to give origin to theſe, in peculiar cells, proper for the reception of the worms which are to be hatched from them. It is obſerved, in examining a hive, that there are always ſome combs, or ſome parts at leaſt of combs, the cells of which are much larger than thoſe of the other parts or combs: theſe large cells are deſtined for the reſidence of the larger worms, which are to produce the drones or male bees. It has been obſerved as a miraculous ſingularity by ſome, that the female bee always knows before-hand, whether the egg ſhe is going to lay will produce a male or a common bee; and that, according to this knowledge, ſhe never depoſits the eggs for a male in a ſmaller cell, nor that of a common bee in a large one; but there is, in reality, leſs wonder in this than is ſuppoſed, for the eggs of which the drones are to be hatched are much larger while in the body of the female than thoſe of which the common bees are to be produced, and the whole occaſion of this choice in regard to the placing of them is, that, when the creature finds a large egg coming forth, ſhe ſeeks one of the large cells to depoſit it in; and when the common ſmall eggs are coming, ſhe contents herſelf with the common cells.

It is very natural to believe, that the female bee lays a third kind of eggs; and that, beſides producing many thouſand common, or working bees, and many hundreds of the males or drones, ſhe ought to lay one egg at leaſt capable of producing a female like herſelf, which is to be the mother of a future progeny, and the queen of the preſent race; ſince, without ſuch a one for their leader, the young brood would never leave the hive in the nature of a colony, and ſettle themſelves elſewhere. What we thus perceive ought to be the caſe, is alſo found in reality to be ſo, and the female, beſides the other kinds of eggs, is found by a ſtrict obſervation to lay alſo eggs of this kind. We might perhaps only expect one female bee to be produced for each ſwarm, but, as nature has ſeemed every where prodigal in the manner of the increaſe of her works, ſo it is in this caſe alſo. What millions of ſeeds are produced on a common elm-tree, for one that ſtrikes and ſucceeds ſo well as to grow up to be a tree? And, of the number of young produced from the ſpawn of a carp, how few live to the ſize of a parent? Thus it alſo is in regard to the female bees: nature, though it has allotted only one of this kind, as abſolutely neceſſary to the new ſwarm, yet has given abundance of chances for that one to ſucceed, by the female's uſually laying at leaſt ten eggs for the production of the female offspring, and often not leſs than twenty: there are, indeed, ſome ſeaſons when

not one female is produced; but in theſe ſeaſons there is no ſwarm going out from the old hive, the creatures being informed by nature, that they have no buſineſs for combs and cells when they can have no offspring to rear in them.

The working bees are not only very obedient to, and very careful of their queen, or female parent; but they are alſo very ſollicitous about her progency. This is very evident in the ſtructure of the cells, which they prepare for the reception of thoſe eggs which are to be hatched into females. It has been before obſerved, that they prepare larger cells for the eggs which are to become drones, or male bees, than for thoſe which are to produce workers like themſelves. The large cells deſtined for the drones are, however, of the ſame ſhape and figure with the others, differing only in ſize; but this is not the caſe with thoſe deſtined for the female offspring: theſe are not only very large, but very clumſily contrived, for the ſake of ſtrength; their ſides being much thicker than thoſe of the reſt, and their figure oval. The bees are extremely ſparing of their wax on all other occaſions, but for the conſtruction of theſe royal cells, as they may not improperly be called, they are as remarkably profuſe: one of the royal cells will weigh more than an hundred and fifty of the common kind. The bees are no more ſparing of the room than of the materials in the conſtruction of theſe royal habitations: they are often placed near the center of a comb, and a vaſt number of other cells are deſtroyed for their baſe; often alſo they hang down from the reſt of the comb, in form of ſtalactitæ from the roofs of ſubterraneous caverns.

A cell of this kind, when firſt formed, repreſents an acorn cup; but it is ſoon lengthened beyond the poſſibility of retaining that figure, and it remains thus till the creature is hatched from the chryſalis or nympth ſtate, and comes out of it; after which the bees, to loſe no room in the hive, form other common cells upon it, and the only remaining mark of the female cell, is the appearance of a knot in the place where it once ſtood.

The number of cells deſtined to receive the eggs which are to produce female bees are ſo few, and they are commonly placed in ſuch cloſe parts of the hive, that there is no great probability of ſeeing the female employed in laying her eggs in them: there is no reaſon to doubt the fact, however, ſince, when we know that ſhe lays eggs for the production of the male and the working bees, there is no wonder that ſhe ſhould alſo lay ſome for the production of females like herſelf.

It might ſeem much harder to conceive how ſo vaſt a number of bees ſhould be produced from this one, as we know are produced from her; but, when one of the females is opened, the vaſt number of eggs diſcovered in each of her ovaries makes the prodigious increaſe no way wonderful.

Swammerdam obſerved, that the number of veſicles in the ovary of the female bee was aſtoniſhingly great; he eaſily counted an hundred and fifty in each ovary, and could count about ſeventeen eggs in each veſicle large enough to be diſtinctly viſible; each ovary contains, therefore, two thouſand five hundred and fifty eggs, and both ovaries five thouſand one hundred. When we find ſo many eggs at once diſtinguiſhable by their ſize, it will be eaſy to conceive, according to the common courſe of nature in the propagation of inſects, that there may be more than as many too ſmall to be yet diſtinguiſhable; and, at that rate, the number of twelve thouſand bees, which is the quantity that compoſes a moderate ſwarm, is not wonderful for the product of the eggs of one female for one ſeaſon. *Reaumur's Hiſt. Inſ.*

QUICK, or *Quickſet-hedge*, a general name for all hedges, of whatever ſorts of plants they are compoſed, to diſtinguiſh them from dead hedges; but, in a more confined ſenſe of the word, it is applied to the white or hawthorn, the ſets or young plants of which are raiſed by the nurſery gardeners for ſale. *See the article* FENCE.

QUICKSILVER, a very ponderous fluid mineral, generally called mercury.

In the year 1765, a diſcovery was made (or rather revived, for it is mentioned by Mr. Bradley) that quickſilver was a ſovereign remedy for deſtroying inſects on trees.

The narrative of this diſcovery was contained in a letter written by Dr. R———; to Dr. P———, in which the former begs the aſſiſtance of the latter "in laying before the learned world an account of ſome experiments, that have been tried with ſucceſs, and which, when fully known, will, he believes, be of very great ſervice to the vegetable part of the creation, by totally deſtroying thoſe pernicious inſects, that are apt to infect the tender leaves and young ſhoots of our choice fruit-trees: and for which, no remedy, that he had ever heard, or read of, has been as yet propoſed, that is either adequate to the diſeaſe, or effectual to the cure." Dr. R———, therefore, in the following part of the letter, deſires Dr. P——— "to lay before the Society for the Encouragement of Arts, &c. the following experiment, that was tried laſt ſpring, with ſucceſs, by one George Bradford, a clothier in the city of Hereford, and a very ingenious young man: in order, after the experiment has been fully tried, they may reward him in proportion as he may ſeem intitled to it." But Dr. R——— adds, that "whether he may be thought worthy of any recompence, or not, he very chearfully ſubmits it to the trial of the curious; and hopes, they may reap the ſame advantages, he did laſt year, by clearing their trees of theſe pernicious inſects." The doctor then proceeds as follows, to give the relation of Mr. Bradford's invention and ſucceſs. "The firſt tree he tried the experiment upon, was a favourite plum-tree: I think a green gage. He was afraid of trying it on the whole body of the tree at firſt: as he did not know, but that it might kill it at once: and therefore he ſelected out a particular branch, that was deſigned to be cut quite away, at the winter pruning, for the ſubject of his firſt eſſay. The method of the experiment is this: he took a ſmall awl, and pierced, ſloping, through the rhind, and into part of the wood of the branch, but not to the heart or pitch of it; and poured in a ſmall drop or two of quickſilver; and ſtopt it up with a ſmall wooden plug made to fit the orifice: and the reſult of this experiment was, that the inſects all dropt off, from that very branch, the next day; and, in a day or two more, from off the other branches of the tree, without any other puncture: and the tree continued in full vigour; and throve well all the ſummer after. Encouraged by this ſucceſs of the firſt eſſay, he next tried it upon a honey-ſuckle; the leaves of which were quite covered with them: and here he ſcraped away the top of the ground with a trowel; and run his awl, in the ſame ſloping manner, into the main ſtem juſt above the roots; but, with the ſame caution as above, not quite to the inner pith; and the ſucceſs was the ſame as before. The inſects all dropt off dead the next day after

after the experiment was made. The above facts you may ſafely depend upon: and I ſaw both the trees, on which the experiments were made, ſince Chriſtmas laſt; and they then ſeemed to be both very healthy and well. I did not, indeed, ſee the operation performed, as I was at that time on my reſidence at L———; but the method, manner, and ſucceſs, as above related, I had from Mr. Bradford's own mouth."

This letter from Dr. R———, was dated March 11, 1765, though the delivery of it to the ſociety was deferred from accident till February laſt. But Dr. P——, in his letter to the preſident, deſiring him to lay the other before the ſociety, remarks, that experiments have been ſince made, which confirms the firſt obſervations. He ſays, "the advantage, however, hath ariſen from this delay, that Dr. R——— hath had fuller proof of the ſucceſs of this diſcovery."

We ſhall only add, that this method has ſince been tried by ſeveral members of the ſociety, and found fully to anſwer the intended purpoſe.

QUINCUNX, a diſpoſition of trees originally formed into a ſquare, conſiſting of five trees, one at each corner, and a fifth in the middle; which diſpoſition often repeated forms a regular grove, and then viewed by an angle of the ſquare or parallelogram, repreſents equal and parallel alleys.

QUIT-RENT, a ſmall rent payable by the tenants of moſt manors, whereby the tenant is quit, or free, from all other ſervices; and is ſaid to be an acknowledgement of their ſubjection to the lord of the manor.

QUITTOR, an ulcer formed between the hair and hoof, uſually on the inſide quarter of a horſe's foot; it often ariſes from treads and bruſes, ſometimes from gravel, which by working its way upwards, lodges about the coronet: if it is only ſuperficial, it may be cured with cleanſing dreſſings, bathing the coronet every day with ſpirit of wine, and dreſſing the ſore with precipitate medicine.

But if the matter forms itſelf a lodgment under the hoof, there is no way then to come at the ulcer, but by taking off part of the hoof; and if this be done artfully and well, the cure may be effected without danger.

When the matter happens to be lodged near the quarter, the farrier is ſometimes obliged to take off the quarter of the hoof, and the cure is then for the moſt part but palliative; for when the quarter grows up it leaves a pretty large ſeam, which weakens the foot: this is what is called a falſe-quarter, and a horſe with this defect, ſeldom gets quite ſound.

If the matter, by its confinement, has rotted the coffin-bone, which is of ſo ſoft and ſpongy a nature, that it ſoon becomes ſo, you muſt enlarge the opening, cut away the rotten fleſh, and apply the actual cautery, or hot iron pointed pyramidically, and dreſs the bone with doſſils of lint, dipped in tincture of myrrh, and the wound, with the green, or precipitate ointment. When the ſore is not enlarged by the knife, which is the beſt, and leaſt painful method, pieces of ſublimate are generally applied, which bring out with them cores, or lumps of fleſh: blue vitriol powdered, and mixed with a few drops of the oil, is uſed alſo for this purpoſe, and is ſaid to act as effectually, and with leſs pain and danger. *Bartlett's Farriery, page* 303.

R.

RABBIT, a well known animal of the hare kind, with a very ſhort tail.

The female or doe rabbit goes with young thirty days, and then ſhe kindles; and if ſhe take not buck preſently ſhe loſes her month, or at leaſt a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in ſome places much ſooner; and they continue breeding very faſt from the time when they begin, four, five, ſix, or ſeven times a year being common with them. They have uſually from four to ſeven in a litter, and hence it is that a ſmall number at firſt will ſoon ſtock a whole warren, if left to breed a little while undiſturbed. The does cannot ſuckle their young till they have been at buck again: this therefore is to be done preſently, elſe there is a fortnight loſt of the time for the next brood, and the preſent brood alſo probably loſt. When the buck goes to the doe, he always beats and ſtamps very hard with his feet, and, when he has copulated with her, he falls backwards, and lies as it were in a trance; in this ſtate it is eaſy to take him, but he ſoon recovers from it.

The buck rabbits, like our boar-cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their ſtocks, or neſts, with gravel or earth, which they cloſe ſo artificially up with the hinder part of their bodies, that it is hard to find them out. They never ſuckle the young ones at any other time than early in the morning, and late at night, and always, for eight or ten days, cloſe up the hole at the mouth of the neſt, in this careful manner, when they go out. After this, they begin to leave a ſmall opening, which they increaſe by degrees, till at length, when they

ere about three weeks old, the mouth of the hole is left wholly open, that they may go out: for they are at that time grown big enough to take care of themſelves, and to feed on graſs.

People who keep rabbits tame for profit, breed them in hutches, but theſe muſt be kept very neat and clean, otherwiſe they will be always ſubject to diſeaſes. Care muſt be taken alſo to keep the buck and does apart till the latter have juſt kindled, then they are to be turned to the bucks again, and to remain with them till they ſhun and run from them.

The general direction for the chooſing of tame rabbits is, to pick the largeſt and faireſt; but the breeder ſhould remember, that the ſkins of the ſilver-haired ones ſell better than any other. The food of the tame rabbits may be colewort and cabbage leaves, carrots, parſnips, apple-rinds, green corn, and vetches, in the time of the year; alſo vine leaves, graſs, fruit, oats, and oatmeal, milk-thiſtles, ſow-thiſtles, and the like; but with theſe moiſt foods they muſt always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwiſe they will grow pot-bellied, and die. Bran and grains mixed together have been alſo found to be very good food. In winter they will eat hay, oats, and chaff, and theſe may be given them three times a day; but when they eat green things, it muſt be obſerved that they are not to drink at all, for it throws them into a dropſy. At all other times a very little drink ſerves their turn, but that muſt always be freſh. When any green herbs or graſs are cut for their food, care muſt be taken that there is no hemlock among it, for, though they will eat this greedily among other things, when offered to them, yet it is ſudden poiſon to them.

Rabbits are ſubject to two principal infirmities. Firſt, the rot, which is cauſed by the giving them too large a quantity of greens, or from the giving them freſh gathered, with the dew or rain hanging in drops upon them. It is over moiſture that always cauſes this diſeaſe; the greens therefore are always to be given dry, and a ſufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moiſture of their juices. On this account the very beſt food that can be given them, is the ſhorteſt and ſweeteſt hay that can be got, of which one load will ſerve two hundred couples a year; and out of this ſtock of two hundred, two hundred more may be eat in the family, two hundred ſold to the markets, and a ſufficient number kept in caſe of accidents.

The other general diſeaſe of theſe creatures is a ſort of madneſs: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This diſtemper is ſuppoſed to be owing to the rankneſs of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called tare thiſtle, to eat.

The general computation of males and females is, that one buck rabbit will ſerve for nine does; ſome allow ten to one buck, but thoſe who go beyond this always ſuffer for it in their breed.

The wild rabbits are to be taken either by ſmall cur dogs, or by ſpaniels bred up to the ſport; and the place of hunting thoſe who ſtraggle from their burrows is under cloſe hedges, or buſhes, or among corn-fields and freſh paſtures. The owners uſe to courſe them with ſmall greyhounds, and, though they are ſeldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets, called purſe-nets, and ferrets. The ferret is ſent into a hole to force them out, and the purſe-net, being ſpread over the hole, takes them, as they come out. The ferret's mouth muſt be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay net or two, at a ſmall diſtance from the burrows that are intended to be hunted: thus very few of the number that are attempted will eſcape.

Some who have not ferrets ſmoak the rabbits out of their holes with burning brimſtone and orpiment. This certainly brings them out into the nets; but then it is a very troubleſome and offenſive method, and is very detrimental to the place, as no rabbit will, of a long time, afterwards come near the burrows which have been fumed with theſe ſtinking ingredients.

RACK, a wooden frame made to hold hay or fodder for cattle.

RADICLE, that part of the ſeeds of plants, which upon vegitating becomes its root, and is diſcoverable by the microſcope.

Woollen RAGS, and the nippings of the pitch-marks upon ſheep, are a ſingularly good manure. The rags ſhould be chopped ſmall, about an inch or two ſquare, and ſcattered on the earth at the ſecond ploughing; for being thereby covered, they will begin to rot by ſeed-time. They imbibe the moiſture of dews and rain, retain it long, and, as Dr. Home obſerves, thereby keeps looſe ſoils in a moiſt ſtate. They coſt about four-pence a buſhel at London, from whence many loads are ſent every year to Dunſtable, which is thirty-three miles, where they are laid even on ſtiff-lands, juſt after the ſowing of the corn, allowing to the acre four ſacks of ſix buſhels each.

RAG-WORT, or as it is called in Yorkſhire, *ſeagrim*, is a very pernicious weed.

The reverend Mr. Camber, of Eaſt-Newton, has obliged the public with the following obſervations on the growth and deſtruction of ragwort, or ſeagrim.

"This plant, ſays he, has a ſtalk, in its early ſtate, green, but, as it advances in age, inclining to violet or purple, eſpecially downwards. Its flowers are yellow, and thick-ſet, and compoſed each of a number of ſmall-pointed leaves. It runs to ſeed in the latter end of ſummer. The ſmell, both of the ſtalk and leaves, which are jagged, (whence probably it obtains one name) and the flower itſelf, are offenſive to all animals, I think; for I have obſerved that hardly any creatures feed upon it, except almoſt hungered or ſtarved. I have not indeed obſerved whether or no aſſes reject it.

"Like moſt other weeds, it thrives beſt in the beſt ſoils, either natural or artificial; and I took up a plant of it in my orchard, about two years ago, (with the root) which, when in flower, touched my chin, (my height is about five feet eight or nine inches) and its root, which is round, and thick ſet with taws, was much larger than a new-born child's head: but the uſual dimenſions are much leſs than theſe.

"About four years ago, I obſerved the ſpreading of this weed in that part of this eſtate which was in our own hands. I took notice, that neither cows nor horſes eat it; and when I ſmelled it, I ceaſed to wonder that they did not. It was obvious to remark, that a weed ſo bulky as this, and ſo groſs muſt extract much nouriſhment from

from the earth, and that it was adviſable to get rid of it as faſt as poſſible. The moſt eaſy method was mowing. I therefore ordered a ſervant to mow theſe weeds in the paſtures as near to the ground as he could; and I hoped that the common mowing in the meadows would be ſufficient to deſtroy them: but I ſoon found my miſtake; for in a very few weeks theſe offenſive ſtrangers ſhot up again into a ſtalk and leaf, and even flower, though all in much ſmaller ſize than before, but with this diſagreeable circumſtance, that the root was ſo far from being injured with the ſcythe, that for one ſtalk ſeveral aroſe, and the roots ſeemed to have gained new vigour from the wound.

"I now applied myſelf to plucking up by the roots of theſe odious inmates, and found new difficulties; for while the ground was dry, as it uſually is in the latter end of ſummer, I found the ſtalks of ſuch of the ſeagrims as were longeſt, and afforded the tighteſt graſp, either break in plucking, and leave the root in the ground entirely, or at beſt bring with it only a ſmall part of the root; and when the wet weather came on, and looſened the ground, and made it poſſible, or even eaſy, to bring away the whole ball of the root, yet the ſeaſon of ſeeding was come on alſo, and the earlieſt ripe ſeeds had diſperſed themſelves, and produced an aſſurance of a larger crop for ſucceeding years than the moſt careful plucking of the preſent crop could deſtroy.

"But if theſe were the difficulties which atttended my attempts to eradicate thoſe ſeagrims, which had happened not to be mowed, I was much more embarraſſed by thoſe which had been; for here it was impoſſible to get any ſuch faſt hold, as to pluck them up with much, or even any root.

"I now applied myſelf to enquire what gentlemen or farmers were plagued with this weed, and what methods they had tried with ſucceſs to deſtroy it.

"I was told by a gentleman in my own neighbourhood, that Sir G. Cayley, of Brompton, near Scarborough, baronet, had been plagued with this weed, and had purſued the method of plucking with ſucceſs.

"Animated by this aſſurance, I reſolved to purſue this method with great attention; and as it ſeemed to be a work which required great care, both in the choice of ſeaſon and manner of plucking, I reſolved not to depute the work to others, but to endeavour to clear a ſpot in my cow-paſture with my own hands, that, if my labour ſucceeded, I might employ others to follow the ſame method under my own eye in the reſt of this paſture.

"Accordingly, in the evenings of the ſummer, or rather autumn, of 1762, after ſhowers, I applied myſelf to this work; and by help of a pair of ſtrong gloves, and a tight graſp, I brought up almoſt every root, in a ſpace of about two hundred yards ſquare, whole; ſo that I had good hopes I ſhould ſee this ſpot clear in the ſucceeding ſummer. It is true, I ſaw leaves of the ſpecies of this weed, and of a very vivid green too, around the plants which I pulled up: but as I reaſonably concluded theſe to be fed by the taws which ſpread themſelves from the main root, ſo I (methought reaſonably) concluded alſo, that this main root being deſtroyed, the ſide taws would die, and conſequently theſe young leaves.

"But how was I diſappointed, when, in the ſummer of 1763, I ſaw this ſpot of ground as much over-run with ſeagrims as any part elſe of the paſture which had been unpulled!

"Converſing, however, with G. Watſon, of New Malton, Eſq; towards the latter end of ſummer, on this ſubject, I was aſſured by him, that by a repetition of this labour of plucking for ſome years, he thought he had leſſened the number of his ſeagrims, though they were ſtill numerous. Urged by this example, I have gone through the whole of my paſture, which is about ten acres, and keeps five cows, at the latter end of laſt ſummer, of 1763, with the ſame care as was uſed to a ſmall part of it in 1762; yet am I not elated with much hope of ſucceſs; for a little plot before my garden (in which my horſes run, and which was managed with ſtill more accuracy on account of the odious appearance of the ſeagrims from my windows) ſeems to threaten another conſiderable crop.

"As I did not confine my enquiries about the method of deſtroying this hateful weed to any one rank of men, I was told by an honeſt quaker, a farmer in my neighbourhood, that he had found turning of ſheep in winter into his cow-paſture the only effectual method of deſtroying this hateful weed.

"I thought this method very likely to ſucceed; for ſheep are ſuch cloſe eaters, that I have known them deſtroy whole beds of the rankeſt docks, which could not be killed by any other means.

"I have not been able to try this experiment conſiderably; for, as I am raiſing quick fences, both in my meadow and paſture, I keep no ſheep. I have, however, occaſionally admitted ſome of my tenants ſheep into the ſmall plot before my garden this winter; and, upon an accurate examination this morning, I do not entertain any ſanguine hopes of great ſucceſs from this method. I find that many of the young leaves of this weed, now level with the ſurface of the ground, are untouched by the ſheep; and that ſuch others as appear bitten by them, do not ſeem in a dying condition.

"The truth ſeems to me, that ſheep, though they may not have the ſame averſion to this weed as horſes and cows, yet are far from being fond of it; and if any great ſucceſs is to be hoped for from their bite, (which may prepare beds for the water, and ſo decay the root) the ſheep ſhould be folded pretty cloſe upon it, and obliged to eat it near, and at ſuch a ſeaſon that the winter-rains may have time to work its deſtruction. And ſuch a method, if carefully purſued, ſeems to be moſt probable for the extirpation of this pernicious weed.

"If the method of plucking is followed, I would ſubjoin ſome cautions.

"Firſt, In order to prevent the large plants from ſeeding, I would adviſe to cut off all the tops, and the tops only, when the flowers begin to die, that then good hold of the ſtalk may be gotten.

"Secondly, I would defer the plucking till the rains have moiſtened the ground ſufficiently to bring up the whole main root.

"Thirdly, I recommend ſtriking the root ſo brought up againſt the ground, in order to diſperſe the earth which adheres to it, by way of manure.

"Fourthly, I always pile the plants thus pulled up and cleanſed from earth, that, if the ſeaſon prove favourable, they may be burnt, and the aſhes ariſing from them ſpread on the ground; or if this cannot be conveniently done, (though it is much the better method, and may, with a ſufficient fire, be done when they are ever ſo green) left to rot and manure the ſoil.

"The

"The groſſneſs, and even ſtench, of this weed, is a proof of the great quantity of ſalts it contains; and in the ſame proportion as any plant exhauſts the ground of its ſalts, it repays when reduced to manure. There can, however, be no queſtion, but whilſt weeds are left to rot, a great quantity of the ſalts, which by burning would mingle with the ſoil, are carried into the air.

"I ſuppoſe your readers will be curious to know in what manner I account for the ſudden appearance of ſeagrims in vaſt abundance, in this eſtate, where they were hardly ever known before.

"I will give you an account, which, I dare ſay, you will eſteem perfectly ſatisfactory. About eight years ago I undertook to improve a piece of ground of about fourteen acres, which was over-run with thorns of both ſorts, brambles, broom, and furze.

"When I had got it cleared of all this traſh, my next buſineſs was to pare the hills off, and pile them, and, after a winter's mellowing, to break and ſpread them with a mixture of lime, and all other kinds of manure which I could collect. As the ſoil was very poor, having been exhauſted by the great quantity of traſh it had nouriſhed for many years, I was not yet ſatisfied, but reſolved to take the advantage of the firſt dry ſummer, to lead out the riches of a pond of about thirty yards long and half as many broad, which had been occupied by a great number of geeſe, &c. and never thoroughly cleaned during near thirty years. I got through this work, though at a great expence, being obliged to employ a conſiderable number of draughts, leſt the rains ſhould make the mud too thin, or the heat bake it too much, the mud being for a conſiderable ſpace a yard perpendicular.

"All this mud I laid on my newly-improved ground, except a few cart-loads, which were brought and laid by the wall of a kitchen-garden, to be mingled with the other ſoil.

"I had divided my improved ground, reſerving about four acres for meadow.

"Behold! the ſucceeding year gave me a crop of ſeagrims both in my new meadow, my new cow-paſture, and the plot of ground in which the mud for my garden had been ſcattered; and more particularly on thoſe parts where the ground had been broke, either to ſtub the thorns, &c. or to take away the hills, while the adjoining ground on each ſide was free from this pernicious weed.

"As I knew little or nothing of this weed, I ſuffered it to ſeed before I took any neceſſary precautions for its deſtruction. The ſucceeding year preſented me with a much larger crop, and I have been ever ſince ſtruggling for its extirpation, and have the mortification to ſee its encroachments on adjoining grounds by the ſeeds which winds have carried.

"This fact, and another of the ſame kind, in a piece of ground which I improved ſince, at ſome diſtance from the former, have confirmed me in an opinion, which I before thought very probable, viz. "That all ſoils are originally impregnated with the ſeeds of almoſt all graſſes and weeds, (though of ſome in greater quantities) which only want a proper ſtirring and manure to awaken them to vegetation, though at the expence of one another, ſome being ſuffocated by that proceſs which gives life to the others."

"I will add another ſtriking inſtance in confirmation of this ſentiment, notorious in this neighbourhood.

"A conſiderable quantity of the park at Gilling was over-run with brakes and moſs, and that wretched graſs which grows in ſuch company. Lord Fairfax, the owner, finding that he could not have his veniſon fat as it ought to be, deſtroyed his park, and applied himſelf ſeriouſly to the improvement of it at a vaſt expence. In courſe of time by due tillage he brought this worſt part of it to be not only good corn-land, but even tolerable, though coarſiſh, meadow and paſture; yet both of them thick ſet with ſeagrims, a weed never ſeen there till the quantity of lime which his lordſhip put into that poor ſoil had warmed it ſufficiently.

"I have only to add, on this ſubject, that I am perſuaded ſeagrim does more harm in meadow than paſture land; for in the latter it only exhauſts the ground, on which it ſtands, to no good purpoſe; but in the former it communicates its diſagreeable ſtench in the ſweat to the good hay, and deſtroys its ſweetneſs. I adviſe, therefore, that hay-makers be ordered to throw it with their rake-ſhafts out of the ſwarthe whenever they meet with it." *Muſeum Ruſticum, vol.* V. *page* 117.

RAM. the male of the ſheep kind. *See the article* SHEEP.

A correſpondent of the editors of the Muſeum Ruſticum has obliged the world with the following method of gelding rams.

"It was, ſays he, a long time before I came into a proper method of gelding my rams: I uſed, like my neighbours, always to employ a common gelder, who cut and ſeared them; however, I obſerved that this not only put the animal to great pain, but was a conſiderable time before it healed, and the ſheep or lamb always loſt fleſh in no ſlight degree.

"Whilſt I was muſing how to improve this practice, a friend of mine, a farmer, who came accidentally to ſee me, out of Bedfordſhire, adviſed me to leave off gelding my rams in the manner I had practiſed, and, inſtead of it, to have them knitted.

"The method of doing this he deſcribed as follows. Firſt take ſome ſmall, yet ſtrong, twine, not too hard twiſted; add three of theſe together, and ſlightly twiſt them on your knee, as the ſhoemakers do their thread; then wax it well with ſhoemakers wax, and it is ready for uſe.

"When you are thus prepared, take a proper length of this twine; tie each end of it to a ſhort bit of ſtick, as thick as a walking-cane; then put it round the cod, and tying a ſingle knot, do you take hold of one ſtick and draw it, whilſt another man draws the other, as tight as you well both can; for on the tightneſs of the drawing depends the ſucceſs of the operation.

"The animal immediately loſes all ſenſe of feeling in the cod, the circulation of the blood thither is ſtopped; and if it was to be let alone, it would rot off, but this is a bad, as well as a naſty and dangerous practice, for the ſheep ſometimes die of the ſtench.

"The beſt way is, at the end of nine days, to cut off the cod; but then you muſt take a great deal of care you do not cut it too cloſe to the tying; if you do, the ſtring may chance to ſlip off, and the conſequence be dangerous as by ſuch a neglect many ſheep may be loſt in a ſeaſon.

"Many farmers, I am informed, when they knit their rams, truſt to the ſtrength of one man's arms; and this may ſometimes be well enough, when your workman is ſtrong, attentive, and willing; but if he is failing in any

of

of theſe points, ten to one but an accident happens: I therefore always chuſe to employ two men at this work.

" The ſeaſon I chuſe is the ſpring of the year, though ſome prefer November, after the ramming ſeaſon is over: I have many reaſons for this preference, and, particularly, I think that the warm weather coming on, hinders them from pining, or falling off their fleſh, and ſoon re-eſtabliſhes them in their perfect health. When this operation is performed in November, and the winter is either wet or froſty, the ſheep are pinched by the cold, and pine away conſiderably, not having that heartening food, to keep them in ſpirits, as they meet with in the ſpring of the year.

" I have obſerved, that if the rams are not in good fleſh, or have not been pretty well fed, they do not undergo this operation ſo well: I therefore always take care to keep them particularly well ſome time before, and alſo ſome time after the buſineſs is done. This is an attention by no means thrown away, for without it ſome miſcarriages may happen, which would otherwiſe be avoided.

" When I ſay I prefer knitting my rams in the ſpring, I mean before the hot weather comes on; as to the particular time, I am governed by the ſeaſon: if it is deferred till ſummer, the flies will ſurely be troubleſome." *Muſeum Ruſticum, vol.* IV. *p.* 159.

In a ſucceeding number of the ſame work, another correſpondent has laid down the following method, which he thinks preferable to the former. He declares he has practiſed it for ten years, and in that time he had not loſt a ſingle one by gelding, out of ſeveral hundreds; neither do they loſe fleſh: on the contrary, ſome of them, that did not thrive before, rather fatten better after, if the paſture does not fail. The ſucceſs he imputes to the evacuation of the humours, by cutting the ſcrotum, &c. may be the occaſion of it.

" What, ſays he, is neceſſary to be obſerved, by way of caution, is as follows. When I am about to have my lambs gelt, I take dry freſh weather to do it in; for which purpoſe I defer it untill they are about two months old, which brings, at leaſt, the middle of May for that work to be performed in; but, in order to have a ſettled ſtate of weather, and the moon in decreaſe, I do it either a little ſooner, or a fortnight later, when I judge the work may be done with ſafety, according to the above caution.

" I have the lambs put into fold that has a good wall, or dyke, about it, by ſeven or eight o'clock in the morning or as ſoon as the dew is off. A man is appointed to ſtand within the fold, with his back againſt the wall or dyke, who may be called the holder: another is appointed to take the lambs, one at a time, taking care not to heat them either in folding or taking them.

" When he has taken a lamb, he brings it to the holder, who takes it by the hinder houghs, and preſſes its back, againſt his breaſt, with its head over his ſhoulder: the operater then, who generally is the ſhepherd, takes his knife, and cuts about an inch from the lower end of the cod quite off: he then puts one of his hands cloſe up to the creature's belly, while he preſſes back the cod with the other; and by that means he cauſes the bare ſtones to put out, ſo that he can eaſily gripe them one at a time with his teeth, and pulls them ſlowly out.

" He then takes a little ſalt water, which is prepared on purpoſe, and ſet near him, into his mouth, and warms it a little; then he ſquirts it up the cod, and all is done; the holder handing the lamb over the wall, or dyke, to one that ſets it on its feet on the other ſide, pulling its tail pretty hard when he lets it go, which makes it ſtretch itſelf out.

" Thus, in half a minute, a lamb is gelt; and in three or four days all danger is over, if kept from lying on nettles, and the like.

" It is proper to walk the lambs gently about three or four hours after they have been half a day gelt.

" If old rams are to be gelt, I do it about the ſame ſeaſon; and the operator takes no other method than that uſed with the lambs, only putting a bit of ſalt and butter up the cod inſtead of ſquirting up a little ſalt water: the holder, indeed, muſt not now ſtand, but ſit on the ground, griping the ram by the houghs, while he lies on his back, with his head over one of the holder's thighs, &c.

" My reaſons for letting the lambs be about two months old before they are gelt, beſides the reaſon before given, are, that at that age they are better able to bear the pain of the operation than when they are young and weakly; and the ſtrings, as they are called, are ſo ſtrong that they do not break, but come entirely out along with the ſtones, which makes a free paſſage for matter to iſſue out by the cod; whereas, when they are gelt very young, as is the practice with ſome, the *tunica albuginea*, or ſtrings as they are vulgarly called, being but weak, they often break, probably occaſioning inflammations, &c. which certainly ought to be avoided, if poſſible. This occaſions more to die, when they are gelt young, by the operation, than when cut at two months old.

" I mentioned having the moon in decreaſe when I have my lambs, &c. gelt, which by ſome, perhaps, will be thought a circumſtance not worth notice: but let ſuch only attend to the wonderful effects the luminaries have on fluids, as well the juices of the animal œconomy, as others, when they are in the poſitions that conſtitute new and full moon; and they will, I dare ſay, be diſpoſed to think the hint is not quite impertinent.

" The reaſonableneſs of my concluſion is not deduced from argument only, but has the authority of experiment, as follows:

" I attempted to geld my lambs, one year, juſt at full moon: the firſt lamb that was cut bled very ſorely; the next did the ſame. I tried as far as half a dozen, and none of them were otherwiſe. I then apprehended there was danger, ſo deferred cutting any more for five days, when there was a great abatement in the bleeding: beſides, one of the ſix gelt at full moon dropt, and none of the others that were gelt five days after did, although they were above twenty times the number of the former (the weather and uſage were nearly the ſame.) This, I own, carried conviction enough for me. Thoſe that will not be convinced by my relation of this fact, I, notwithſtanding, do heartily wiſh them no worſe luck than I have had in that way; but withal they had as good uſe circumſpection. *Muſeum Ruſticum, vol.* IV. *page* 331.

RAPE, the name of a plant much cultivated for its ſeed, and alſo as a food for cattle. *See the article* COLE.

RAT, the name of a well known animal, very troubleſome to the farmer, &c.

We ſhall here give the two following receipts, as they are ſaid to be effectual, for deſtroying rats.

The firſt has the ſanction of the Dublin Society, who on the 19th of November 1762, ordered a premium of five

five guineas to one Laurence O'Hara, for this diſcovery; which is, "one quart of oat-meal, four drops of rhodium, one grain of muſk, and two nuts of nux vomica finely raſped." This mixture is to be made up in pellets, and laid in the holes and places which the rats frequent.

The other receipt is thus: "Take of the ſeeds of ſtaves-acre, or louſe-worth, powdered, one fourth part, and of oatmeal three parts; mix them well and make them up into a paſte with honey. Lay pieces of it in the holes, and on the places frequented by rats or mice, and it will kill ſuch of thoſe vermin as eat thereof." *Gent. Mag. March* 1763.

The firſt ſtep taken by rat-catchers, in order to clear a houſe, &c. of thoſe vermin, is to allure them all together to one proper place, before they attempt to deſtroy them; for there is ſuch an inſtinctive caution in theſe animals, accompanied with a ſurpriſing ſagacity in diſcovering any cauſe of danger, that, if any of them be hurt, or purſued, in an unuſual manner, the reſt take the alarm, and become ſo ſhy and wary, that they elude all the devices and ſtratagems of their purſuers for ſome times after. This place, where the rats are to be aſſembled, ſhould be ſome cloſet, or ſmall room, into which all the openings, but one or two, may be ſecured: and this place ſhould be, as near as may be, in the middle of the houſe, or buildings. It is the practice, therefore, to attempt to bring them all together in ſome ſuch place, before any attempt be made to take them; and, even then, to avoid any violence, hurt, or fright to them, before the whole be in the power of the operator.

The means uſed to allure them to one place are various: one of thoſe moſt eaſily and efficaciouſly practiſed is, the trailing ſome piece of their moſt favourite food, which ſhould be of the kind that has the ſtrongeſt ſcent, ſuch as toaſted cheeſe, or broiled red-herring, from the holes or entrances to their acceſſes in every part of the houſe, or contiguous buildings, whence it is intended to allure them. At the extremities, and in different parts of the courſe of this trailed tract, ſmall quantities of meal, or any other kind of their food, ſhould be laid, to bring the greater number into the tracts, and to encourage them to purſue it to the center place, where they are intended to be taken: at that place, where time admits of it, a more plentiful repaſt is laid for them, and the trailing repeated for two or three nights.

Beſides this trailing, and way-baiting, ſome of the moſt expert of the rat-catchers have a ſhorter, and perhaps more effectual, method of bringing them together; which is, the calling them, by making ſuch a kind of whiſtling noiſe as reſembles their own call; and by this means, with the aſſiſtance of the way-baits, they call them out of their holes, and lead them to the repaſt prepared for them at the place deſigned for taking them. But this is much more difficult to be practiſed than the art of trailing; for the learning the exact notes, or cries, of any kind of beaſts or birds, ſo as to deceive them, is a peculiar talent, not eaſily attained to in other caſes.

In the practiſing either of theſe methods, of trailing or calling, great caution muſt be uſed, by the operator, to ſuppreſs and prevent the ſcent of his feet and body from being perceived; which is done by overpowering that ſcent by others of a ſtronger nature. In order to this, the feet are to be covered with cloths rubbed over with aſſa fœtida, or other ſtrong ſmelling ſubſtances; and even oil of rhodium is ſometimes uſed for this purpoſe, but ſparingly on account of its dearneſs, tho' it has a very alluring, as well as diſguiſing effect, as will be obſerved below. If this caution of avoiding the ſcent of the opperators feet, near the track, and in the place where the rats are propoſed to be collected, be not properly obſerved, it will very much obſtruct the ſucceſs of the attempt to take them; for they are very ſhy of coming where the ſcent of human feet lies very freſh, and intimates, to their ſagacious inſtinct, the preſence of human creatures, whom they naturally dread. To the above-mentioned means of alluring by trailing, way-baiting, and calling, is added another of very material efficacy, which is, the uſe of oil of rhodium, which, like the marum lyriacum in the caſe of cats, has a very extraordinary faſcinating power on theſe animals. This oil is extremely dear, and therefore ſparingly uſed. It is exhaled in a ſmall quantity in the place, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be laſt brought together, in order to their deſtruction; and it is uſed alſo, by ſmearing it on the ſurface of ſome of the implements uſed in taking them by the method below deſcribed: and the effect it has in taking off their caution and dread, by the delight they appear to have in it, is very extraordinary.

It is uſual, likewiſe, for the operator to diſguiſe his figure as well as ſcent; which is done by putting on a ſort of gown or cloak, of one colour, that hides the natural form, and makes him appear like a poſt, or ſuch inanimate thing; which habit muſt likewiſe be ſcented as above, to overpower the ſmell of his perſon: and beſides this, he is to avoid all motion, till he has ſecured his point of having all the rats in his power.

When the rats are thus enticed and collected, where time is afforded, and the whole in any houſe and out-buildings are intended to be cleared away, they are ſuffered to regale on what they moſt like, which is ready prepared for them, and then to go away quietly for two or three nights; by which means thoſe, which are not allured the firſt night, are brought afterwards, either by their fellows, or the effects of the trailing, &c. and will not fail to come duly again, if they are not diſturbed or moleſted. But many of the rat-catchers make ſhorter work, and content themſelves with what can be brought together in one night or two; but this is never effectual, unleſs where the building is ſmall and entire, and the rats but few in number.

The means of taking them, when they are brought together, are various. Some entice them into a very large bag, the mouth of which is ſufficiently capacious to cover nearly the whole floor of the place where they are collected; which is done by ſmearing ſome veſſel, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of food. This bag, which before lay flat on the ground with the mouth ſpread open, is to be ſuddenly cloſed when the rats are all in it. Others drive, or fright them, by ſlight noiſes or motions, into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being ſecured. Others, again, intoxicate or poiſon them, by mixing with the repaſt prepared for them, the coculous Indicus, or the nux vomica. A receipt for this purpoſe has appeared, which directed four ounces of the coculus Indicus, with twelve ounces of oatmeal, and two ounces of tracle or honey, made

made up into a moiſt paſte with ſtrong beer; but if the nux vomica be uſed, a much leſs proportion will ſerve than is here given of the coculus. Any ſimilar compoſition of theſe drugs, with that kind of food the rats are moſt fond of, and which has a ſtrong flavour, to hide that of the drugs, will equally well anſwer the end. If, indeed, the coculus Indicus be well powdered, and infuſed in the ſtrong beer for ſome time, at leaſt half the quantity here directed will ſerve as well as the quantity before-mentioned. When the rats appear to be thoroughly intoxicated with the coculus, or ſick with the nux vomica, they may be taken with the hand, and put into a bag or cage, the door of the place being firſt drawn to, leſt thoſe which have ſtrength and ſenſe remaining eſcape.

By theſe methods, well conducted, a very conſiderable part of the rats in any farm, or other houſe, and the contiguous buildings, may be taken. *Muſeum Ruſticum, vol.* I. *page* 395.

RAT-TAILS, excreſcences which creep from the paſtern to the middle of the ſhanks of a horſe, and are ſo called from the reſemblance they bear to the tail of a rat. Some are moiſt, others dry; the former may be treated with drying ointment and waſhes, the latter with mercurial ointment. If the hardneſs does not ſubmit to the laſt medicine, it ſhould be pared off with a knife, and dreſſed with turpentine, tar, and honey, to which verdigreaſe or white vitriol may occaſionally be added; but before the uſe of the knife you may apply this ointment.

Take black ſope, four ounces, quick-lime, two ounces, vinegar enough to make an ointment. *Bartlet's Farriery, page* 296.

RED-CLOVER. *See the article* CLOVER.

RED-GAME, an Engliſh name of a bird, common in the mountainous parts of Yorkſhire, and ſome other of our northern counties. It is of the ſhape of a partridge, but much larger, and of a mixed colour of red and black, and is feathered down to the ends of the toes.

RED-LAND, a term much uſed by huſbandmen to expreſs a ſandy ſoil of a reddiſh hue, interſperſed for the moſt part with pieces of ſand-ſtone of the ſame colour, or ſomewhat deeper.

There are ſeveral varieties of this ſoil, one of which is almoſt entirely made up of ſand; another with an admixture of clay with the ſand, the whole making a looſe loamy earth; and a third, full of fragments, of a poor ſandy iron ore, and often containing ſhining ſpecks of ſelenitæ. *Moreton's Northamptonſhire.*

RED-WORM, the name of an inſect very deſtructive to young corn.

"I have often (ſays Mr. Baker, in his report to the Dublin Society) heard of the havock which red-worms make in young wheat, barley, and oats; and in ſome few writers upon huſbandry have read of them: but never ſaw them till May 1764; when to my great mortification, in a few days, they deſtroyed, almoſt totally, nine acres of my wheat, for I did not reap above half a barrel per acre. This misfortune induced me to propoſe to the conſideration of the Dublin Society, whether the offer of a premium might not probably produce a diſcovery of ſome effectual method for deſtroying ſo injurious an inſect, to the infinite advantage of the public: and the ſociety were pleaſed to offer a premium accordingly.

"I have now the honour to lay before them, what has occurred to me upon that ſubject.

"The moſt ingenious M. de Chateauvieux ſpeaks of an inſect, which is certainly the ſame kind, if it be not the very inſect which I have now under conſideration. This gentleman, after ſaying, "our wheat, in the month of May, 1755, ſuſtained a loſs, which even that cultivated according to the New Huſbandry did not eſcape, deſcribes the worm thus: we found in it many little white worms, which afterwards became of a cheſtnut colour. They poſt themſelves between the blades, and eat the ſtems. They are uſually found between the firſt joint and the roots; every ſtalk, which they attacked, grew no more, but became yellow, and withered. The ſame misfortune happened to us in the year 1732. The inſects appeared about the middle of May, and made ſuch havock, that the crops were almoſt deſtroyed."

"It perhaps might be expected, that this great man ſhould have made the very enquiry which we are now upon, as the loſs appears to have been very great in Geneva, at the two periods which he mentions: but when we conſider, how much the high office, which he held in the city and republic of Geneva, muſt have engaged his attention, it is rather aſtoniſhing, that he could oblige the world ſo much as he hath done, by his repeated experiments in huſbandry, and his judicious obſervations upon them: it is therefore leſs to be wondered at, that this circumſtance eſcaped him.

"The ingenious Mr. Benjamin Stillingfleet alſo, in the ſecond edition of his Miſcellaneous Tracts, in a note, page 175-6, ſpeaks of an inſect, which is probably the ſame as that which we are ſeeking to deſtroy. His words are,

"Thus in Suffolk, and in ſome parts of Norfolk, the farmers find it their intereſt to encourage the breed of rooks, as the only means to free their grounds from the grub, from which the tree or blind-beetle comes, and which in its grub ſtate deſtroys the roots of corn and graſs, to ſuch a degree, that I myſelf have ſeen a piece of paſture-land, where you might turn up the turf with your feet.

"Mr. Matthews, a very obſerving and excellent farmer, of Wargrove in Berkſhire, told me, that the rooks one year, whilſt his men were houghing a turnip field, ſate down in part of it, where they were not at work, and that the crop was very fine in that part, whereas in the other part there were no turnips that year.

"We ſee, that M. de Chateauvieux deſcribes this worm as being firſt white, and afterwards becoming of a cheſtnut colour. I have carefully ſought them at different periods during the paſt year, but always found them of the ſame cheſtnut colour, never varying in any particular; except that of ſize, which I find to be the caſe at all ſeaſons, in which I have ſeen them.

"The inſect which Mr. Stillingfleet ſpeaks of, he calls a grub, which, he ſays, deſtroys corn and graſs: this induces me to believe, that it is the ſame inſect (though the report which he relates from Mr. Matthews ſeems to contradict it) becauſe I have obſerved, that the red or cheſtnut worm, never appears voluntarily upon the ſurface; but, when the earth is turned up, either with plough or ſpade, the rooks and crows are very bold in their approach to pick them up; a circumſtance, which I own has in ſome degree abated my enmity to theſe birds: I therefore never deſtroy nor frighten them off my land whilſt I am ploughing it; but when I ſow, when the corn riſes, and when it is ripe, I deſtroy or baniſh them as well as I can,

 becauſe

becauſe the miſchief which they do at thoſe times is intolerable.

" A member of the Dublin Society informed me laſt ſummer, that ſome of his turneps were deſtroyed by a worm; I had ſome few which decayed in their leaves, and became of a lemon colour, preceding the putrefaction which followed, and deſtroyed the turneps: I examined their roots, but could not diſcover any inſect which had injured them, and therefore I cannot pronounce that it is the red-worm which deſtroyed this gentleman's turneps; but I ſhall be very watchful with reſpect to this circumſtance, upon every opportunity which may preſent itſelf.

" I have obſerved my lucerne to decay in its tops, ſoon after it has been up; and upon examining the roots, I have found the red-worm, which had cut them off.

" This inſect ſeems to be every where in Ireland called the red-worm; by ſome of the Engliſh writers who have ſpoken of an inſect, which deſtroys corn in the manner already mentioned, which I think is undoubtedly the ſame: it is called a grub, by others the large maggot, and the rook worm, becauſe the rooks eat it; but as none of the writers have given any other deſcription of it, than the name by which they reſpectively call it, I ſhall endeavour to deſcribe it.

" Red-worms are about half an inch long, and about one tenth of an inch in diameter: they are jointed in their ſkins, and are of a very firm texture: they have many ſhort legs, two ſmall black ſpecks, which appear to be their eyes; and two ſmall points ſpringing from their heads, with which I believe they cut the corn, and which, in that work, I apprehend, act like forceps: and all that I have ſeen of this ſpecies, are of a bright cheſtnut colour. For this reaſon, I ſhould conceive it would be more deſcriptive to call them the cheſtnut worms.

" When they are expoſed to the air, by turning up the earth which is infeſted with them, they will very ſoon cover themſelves again in the ſoil, which they are very capable of doing, by the ſtrength which their make gives them, although they appear to be a ſluggiſh inſect, and have not the advantage of a ſlimineſs upon their ſkins, which the common large creeping worm has, which enables that inoffenſive worm to penetrate the earth, and get under timber and ſtones with eaſe.

" The red-worm, immediately endeavouring to cover itſelf from the air, is certainly from natural inſtinct, as it will ſoon die, when expoſed to the air; as will appear by the experiment, Numb. 10, hereafter mentioned.

" Theſe worms deſtroy wheat, barley, oats, and lucern, while in an infant ſtate, in the months of March, April, and May. Late-ſown barley and oats, they will deſtroy as late as June. I have not yet experienced, that they deſtroy any other crops.

" The miſchief done by them is in dry weather. Rain ſufficient to penetrate the ground, makes them deſiſt from deſtroying the corn; and, I ſuppoſe, every thing elſe which they at any time injure.

" They cut wheat off, juſt above the crown of the roots; barley and oats in the ſame place, and alſo higher up, upon any part of the ſtem, which is below the ſurface of the earth.

" Theſe worms ſeem to abound more in ground which is lightly tilled, than in ſuch as hath been well tilled; but, in lay ground, they ſeem to be more numerous than any where elſe: and the fields upon my farm, in which I have found them, are wetter than other fields where they are not; whether that circumſtance contributes to their increaſe, I cannot ſay; but the following experiments prove, that they will live longer in water than they can when expoſed to the open air.

" *Experiments on Red-worms.*

" Numb. 1. I put ten red-worms into a wine-glaſs with common ſalt in it. They were all dead in four hours.

" Numb. 2. Into a glaſs with brine in it I put ten red-worms. They were all dead in ſix hours.

" Numb. 3. Into a glaſs with lime in it, which had been ſlaked for a long time, and expoſed to the weather, I put the like number. They were all dead in forty-four hours.

" Numb. 4. Into a glaſs with the above lime, and ſome water in it, I put the like number. They were dead in twenty hours.

" Numb. 5. Into a glaſs with lime newly ſlaked, and when cold, I put the like number. They were dead in fourteen hours.

" Numb. 6. Into lime-water, made with cold water, I put the like number. They were dead in ten hours.

" Numb. 7. Into a glaſs with ſoot in it, I put the like number. They were dead in four hours.

" Numb. 8. Into ſoot and water, I put the like number. They were dead in four hours.

" Numb. 9. Into fair water, I put the like number. They were dead in fifty-two hours.

" Numb. 10. Into a glaſs, without any thing in it, I put the like number. They were dead in thirty-two hours.

" By theſe experiments we ſee all the articles uſed will kill this inſect in a ſhort time, particularly the ſalt and ſoot. I thought it neceſſary to conſider different articles, the better to ſuit different parts of the kingdom.

" Where lime can be conveniently had, and that it is uſed as a manure, I am apt to believe, from the experiments, that no injury can be ſuſtained from theſe worms; but I am afraid a ſmall quantity will not effectually deſtroy them; beſides, I ſhould fear, if it were not put on before the ſowing of the corn, that it might finge the blades of the corn; for, from theſe experiments, it appears, that lime newly ſlaked, is more ſuddenly deſtructive to them than old lime, and therefore it is to be preferred.

" Where lime is uſed for no other purpoſe than to deſtroy this worm, I ſhould conceive, that about eight barrels, regularly ſown by hand on an acre of ground, might be ſufficient: it muſt be firſt ſlaked and cold before a man can poſſibly caſt it upon the ground with his hand, lime being a very ſtrong cauſtic; and, even when it is cold, the man ſhould have a thick glove upon his hand.

" Where ſalt ſhall be uſed to deſtroy this worm, it muſt always be ſown upon the ground, before the intended crop; for, although corn will vegetate, and receive benefit from ſalt as a manure, when it is uſed antecedent to the ſowing the corn, yet, if it be added after the corn is growing, it will certainly deſtroy it: and therefore, it ſhould never be uſed for this purpoſe, but before the corn is ſown, or at leaſt before it vegetates.

" I conceive that where ſalt is uſed for this purpoſe only,

only, about four hundred and a half to an acre will anſwer the purpoſe, which is a trifle more than one ounce to every ſquare yard.

"We ſee by the experiment, that ſoot kills this worm as ſoon as ſalt; and as in moſt places it is to be had at a much leſs price than ſalt, I think there can be no doubt about preferring of it; beſides which, it may be ſafely uſed after the corn is up.

"I had ſome ſmall parcels of barley under experiments, which theſe worms began to deſtroy; and in order to convey the ſoot as ſoon as poſſible to the roots of the plants, I mixed a little of it in water, and poured it on the plants with a garden watering pot; the conſequence was, that I did not loſe one plant afterwards.

"It will hardly be imagined, that I mean that the ſame method is to be purſued upon a whole farm: no; the method I would recommend to the practice of the farmer is this, to ſpread or caſt by hand, as he ſows his corn, about ſix or eight barrels of ſoot on an acre, and let him be careful to chooſe a calm day for the work, otherwiſe the wind will carry away great part of it: and as what remains cannot be regularly diſpoſed, let him be careful to do it early enough in the ſpring, that the rain may waſh the ſoot and convey it to the roots of the plants, before the worm begins the miſchief; if he does this, I am perſuaded his crop will be preſerved.

"We ſee by the experiments, that this worm will live longer in water, by twenty hours, than when expoſed to the open air; but at length, i. e. in fifty-two hours, they died in the water; perhaps this might be from the effect of drowning; but if ſo, I might have expected they would have been totally deſtroyed in my two fields in the winter of 1763 and 1764, by the immoderate rains which fell at that ſeaſon for a long continuance, by which the land was often flooded. But they ſurvived that winter, as appeared by the great loſs I afterwards ſuſtained, by their deſtroying my wheat; and therefore, whether water be an enemy to them or not, it ſeems not eaſy to determine: but if theſe which died in the glaſs of water were really drowned; yet, I think we may conclude, that water is neceſſary to their exiſtence in the earth, and probably aids them in getting their food from it: and what ſeems to confirm this notion is, that when the land is wet, they do not touch the corn, but as ſoon as ever the land is dry, they begin their miſchief. However, this ſpeculation I muſt ſubmit to the conſideration of perſons more capable of diſcuſſing it than I am.

"We ſee by the experiment, Numb. 10, that they cannot live in the open air; which ſeems to prove, that, where they abound in land, the oftener it is ploughed, particularly in the ſummer, when they cannot penetrate the ground ſo eaſily as when it is moiſt, they muſt be, by ſuch ploughing, greatly diminiſhed; beſides which, the frequent ploughing gives the crows more opportunities of picking them up, in which, as I before ſaid, they are very watchful.

"Frequent ploughing has been recommended by ſome writers as the only means of deſtroying this worm; and they have recommended the ploughs being ſtuck with nails, urging, that by thoſe nails the worms are cut to pieces; others have recommended walnut leaves being ſoaked in water, to ſprinkle the land; and ſteeping ſeed-corn in various liquors, as infallible remedies: but ſuch methods as theſe are founded upon miſtaken principles; they only miſlead the farmer, and muſt diſappoint him.

"Worlidge recommends a ſtrong lye made of fixed ſalts, but that would be impracticable. Mortimer recommends ſea-water, for ſuch lands as are near the ſea-coaſt, which I believe would anſwer very well. He ſays he uſed ſoot once with ſucceſs, but that it did not ſucceed with him afterwards. I am perſuaded he did not uſe the ſoot early enough to have it waſhed into the ground by rain, or perhaps he uſed too ſmall a quantity.

"I would not be thought to arrogate any merit to myſelf, on account of what I have here offered, on this ſubject, ſince it appears, that other perſons have uſed the articles which I have recommended, againſt this common enemy; but many perſons have been diſappointed in their expectations from theſe remedies, which muſt have ariſen from their either having uſed too ſmall a quantity, or not having obſerved the neceſſary precautions; if thoſe, which I have recommended, ſhall be put in practice, and found to anſwer, I ſhall think myſelf amply rewarded."

REEK. *See the article* STACK.

REEK-STAVEL, *or* REEK-STAFFOLD, a frame of wood placed on ſtones, on which the mow or ſtack is raiſed.

REED, the name of an aquatic plant, infeſting low paſture-lands.

The beſt method of deſtroying reeds, is by draining the land; for if the drains be cut deeper than their roots, it will take away their nouriſhment, and, conſequently, deſtroy them. Aſhes, or ſoot, will likewiſe kill them; and ſo will ploughing up the land, and laying it in high ridges. They always indicate a good ſoil, for a bad one will not nouriſh them.

REY-*graſs*, a hardy ſort of graſs, much eſteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing elſe will. It thrives beſt of all on ſour, clayey, and weeping grounds, and equally endures the ſevereſt droughts of ſummer, and froſts of winter, ſuffering no damage from either. It is the beſt of all winter foods for cattle, the ſhorter it is eaten the better, and it ſprings the earlieſt of any. There is no danger of over-ſtocking it, for, if it be left to grow too much, the ſtalk becomes hard and ſticky. It is beſt for horſes and for ſheep, and very much prevents the rotting of the latter. The beſt way of ſowing it is with clover. The common quantity of ſeed is two buſhels to an acre, but three buſhels is much better; though in ſome lands, where the clover is likely to ſucceed very well, they ſow eight pounds of clover ſeed and one buſhel of rey-ſeed to an acre, and this makes a crop that will laſt ſeven or eight years.

Some mow it as hay, and thraſh it for the ſeed, which, about London, ſells from half-a-crown a buſhel to three ſhillings. Four or five quarters of this ſeed will be ſometimes produced from an acre of the graſs. If at any time a field of this graſs is found to grow thin, it is only neceſſary to ſtrew on a buſhel of the ſeed, and roll it with a wooden roller, and the plants riſing from this addition will make the whole crop ſufficiently thick. Rey graſs has this great advantage, that it kills weeds without any other ſown plant: even thiſtles cannot grow among it. When the rey-graſs is cut for hay before perfectly ripe, the hay is the better; but the ſeed will not grow ſo well. When the ſeed is newly thraſhed, it muſt not be laid too thick, for it is very apt to heat and ferment, and the whole will be ſpoiled. *Mortimer's Huſbandry, vol.* I. *page* 40.

RICE, the name of a plant cultivated in many parts of

the eaſt, in South-Carolina, and alſo in Spain, Italy, and Piedmont.

The plant grows to the height of about two feet and a half, with a ſtalk not unlike that of wheat, but fuller of joints, and with leaves reſembling thoſe of a leek. It branches out into ſeveral ſtems, at the top of which the grains grow in cluſters, and each of them is terminated with an arum or beard, and incloſed in a yellow rough huſk. When ſtripped of this they appear to be of an oval ſhape, of a ſhining white colour, and almoſt tranſparent.

The following account of the culture of rice in China, is taken from M. Duhamel's Huſbandry.

" 1. To haſten the ſprouting of the rice, it is put into baſkets, and ſoaked for ſome days in a ſtanding water.

" 2. When their rice grounds are ſo ſoaked with water as to be quite like mud, they plough them with a buffalo yoked to a plough very ſimple in its make, having but one ſhare, one handle, and no wheels.

" 3. After a gentle rain, they break the clods with a kind of large hurdle, drawn by a buffalo; the driver ſitting upon it, to increaſe the weight.

" 4. The ground is cleared of all ſtones, and whatever roots are in it are pulled up by a ſtrong harrow, with great iron teeth. This inſtrument is drawn by a buffalo, and a man guides it with the help of two handles, like thoſe of a plough, upon which he leans hard. The earth is like mud, and partly covered with water during all this operation.

" 5. The earth is afterwards ſmoothed with a harrow, which has ſeveral rows of teeth. A man guides this harrow by its two handles, whilſt a buffalo draws it; and as faſt as its teeth form little channels in the ground, the water runs in, and fills them up.

" 6. When the rice that was laid to ſoak has ſprouted, the ſeed is known to be good; and it is then ſown by hand, very thick, and as equally as poſſible. Only part of the ground is ſown in this manner, to furniſh plants for the reſt.

" The day after it has been ſown, the points of the plants appear above the ſurface of the water: for the ground is overflowed all this time with juſt enough water to cover it.

" 7. When the plants have acquired a little ſtrength, they are ſprinkled with lime water, to deſtroy the inſects and ſome of the weeds that would hurt them. For this purpoſe a ſmall baſket is faſtened to the end of a long handle, and dipt in the lime-water, which runs through it, and is conveyed over the plants.

" The Chineſe have a great veneration for the firſt inventor of this method, which anſwers to our cuſtom of ſteeping wheat in lime-water, or manuring land with quick-lime.

" 8. Towards April, when the plants are grown ſtrong enough to cover the whole field, and look very green and even, the greateſt part of them is pulled up by handfuls, all the mud is carefully waſhed off their roots, and, being held all this time as even as poſſible with one another, they are planted in tufts, pretty far aſunder, and in a quincunx form, in fields prepared on purpoſe for them. A ſerene day is choſen for this operation, which muſt be performed as quick as poſſible.

" This practice of the Chineſe is with reſpect to the common culture of rice, what the New Huſbandry is with reſpect to the common culture of wheat.

" 9. The rice muſt be watered: which is always done in China, by overflowing it. To this end, the rice grounds are always near a rivulet, pond, or great pool of water, from which they are ſeparated only by a bank or cauſey.

" If the water was higher than the rice ground, a trench cut through the cauſey would overflow it an once: but as it is generally lower, or on a level with the rice ground, the neceſſary quantity is conveyed in pails or buckets, which are worked chiefly by the help of ropes.

" 10. Though a man cannot ſtep in theſe rice grounds without being up to his knees, the Chineſe weed them three times in a ſummer; and that with ſuch care, that they pull up even the roots of every weed.

" 11. When the rice is ripe, which is known by its turning yellow like wheat, it is cut down with a ſickle, made into ſheaves, and carried to a barn, where it is threſhed with flails pretty much like ours: the ſtraw is removed with pitch-forks and ſhovels, and the outer huſk of the grain is taken off by beating it with great wooden peſtles, or a kind of mallet, after which it is ſifted and winnowed: and, laſtly, to get off the under huſk, the grain is put between two mill-ſtones, which are worked by a lever faſtened to the upper one.

" The two moſt remarkable circumſtances of this culture are, 1. The care which the Chineſe take not to let their plants be too cloſe together, leſt they ſhould rob one another of their food. 2. Their weeding their rice grounds three times in a ſummer, which anſwers the end of the hoeings recommended for the alleys between the beds of other grain, cultivated according to the New Huſbandry." *Culture des Terres, Tom. II. p.* 180.

RICK, a pile of corn, hay, ſtraw, &c. regularly heaped up in the open air, and ſheltered from wet. *See* STACK.

A practical farmer has given the following account of the benefits ariſing to the farmer from keeping his wheat-ſtraw in ricks, to be uſed when occaſion requires it.

" Experience will, they ſay, make a fool wiſe: I took the hint, and have ever ſince guarded againſt a misfortune of the like nature.

" I conſtantly, ſays he, every year make a rick of wheat ſtraw, unleſs it happens to be very ſhort, when I keep my rick two years, inſtead of making a new one the ſecond year.

" This may, and doubtleſs will, by ſome of your readers, be thought an unneceſſary expence; yet, as I find it anſwer, I am determined to continue the practice. I not only rick the ſtraw, but I alſo ſlightly thatch the rick to keep out the weather; yet, after all, I ſave by it.

" As I keep a very regular account of my farming expences, I find that in the ſpace of ten years I am a gainer of fifty-three pounds, by ſaving in this manner a rick of ſtraw for thatching, beſides what I ſaved by not threſhing my wheat at an improper ſeaſon. When I ſay I am a gainer of ſo much money in the time, I mean a clear gain: after deducting the expences of making up the rick, thatching it, &c. my expences in thatching for the laſt ten years have been fifty-three pounds leſs than they were the ten preceding years; and this I can eaſily account for, and will, for the ſatisfaction of your readers, at leaſt in part, do it.

" I now always do my thatching work at the moſt convenient ſeaſon, being never in want of ſtraw; and, for the ſame reaſon, as ſoon as any part of my thatching is deficient,

deficient, I have it immediately repaired, which is a great ſaving.

" My thatching now laſts longer than it uſed to do, for I never thatch with ſhort ſtraw, having always, as I obſerved before, long ſtraw to uſe; for in the years when the ſtraw is long, I ſave the largeſt rick, which I have ſometimes kept two or three years, till the wheat ſtraw has been long again.

" In the ſpace of the laſt ten years I had two accidents happened, which would have proved very expenſive to me, if I could not have reſorted to my ſtraw rick.

" The firſt was, that one of my ſons (a boy about ten years of age at the time) ſet fire to the thatch of a large barn by means of a ſquib. It burnt furiouſly for ſome time, and ſo far damaged the roof, that I was obliged to have it new thatched; for which purpoſe I made uſe of a part of my ſtraw rick, and it was finiſhed in a few days; whereas, if I had not had this rick, I muſt have bought ſhort ſtraw, for there was ſcarcely any other to be had, at a large price, and the thatching could not have been finiſhed ſo ſoon; by which means I ſhould have had a conſiderable quantity of barley, that was in the barn, damaged, for it rained very hard, for a conſiderable time, in a few days after the thatch was repaired.

" The other accident was occaſioned by a guſt of wind which ſtripped off a good deal of thatch; but it was ſoon repaired, without any damage to the corn that was in the barns at the time.

" All this, perhaps, may not be enough to perſuade your practical readers to rick their long ſtraw. If this is the caſe, they muſt even continue their old practices: yet I hope I may be permitted to ſay one thing, which I know to be true; what I mean is this, that farmers, if they would attend to matters which they generally think beneath their conſideration, would get more money than they do: profits ariſe from what appear to be trifles at firſt ſight, and the mereſt trifle ſhould be by a farmer attended to.

" A habit of induſtry, frugality, œconomy, and perſeverance, is abſolutely neceſſary to the occupier of land, if he does not mean ſoon to ſhift his quarters." *Muſeum Ruſticum*, *vol.* III. *p.* 245.

RIDDLE, an oblong ſort of ſieve uſed to ſeparate duſt, and the ſeeds of plants from corn.

RIDE, a cluſter of ſprigs of hazel, or the under-wood, ſhooting out of the ſame root.

RIDGE, a long piece of riſing land between two furrows.

Mr. Tull obſerves, that the method of ploughing lands up into ridges is a particular kind of tillage, the chief uſe of which is the alteration it makes in the degrees of heat and moiſture. But the principal advantage this gentleman propoſes from ridges is the draining wet hills, where the upper ſtratum is mould, and the ſecond ſtratum clay. Theſe ridges he obſerves ſhould be ploughed acroſs the hill, almoſt horizontally, that their parting furrows lying open, may each ſerve as a drain to the ridge next below it; for when the plough has made the bottom of theſe horizontal furrows a few inches deeper than the ſurface of the clay, the water will run to their ends very ſecurely, without riſing into the mould, provided no part of the furrows be lower than their ends. Theſe ridges and their parting furrows muſt be made more or leſs oblique, according to the form and declivity of the hill; but the more horizontal they are, the ſooner the rain-water will run off the lands: for in that caſe, it will run to the furrows, and reach them at right angles. Every one of theſe horizontal trenches receives all the water from the rills, or little gutters, which in theſe quagmire-hills run betwixt the mould and the clay; theſe are all cut off by the trenches, which receives the water at their upper ſides, and carry it away, as the gutters of lead, placed under the eaves of a houſe, carry away the rain-water. Theſe ridges ſhould be ploughed in pairs, without throwing any earth into the trenches; and at every time of ploughing, the pairs muſt be changed, ſo that the furrow which had two ridges turned towards it one time, muſt have two turned from it the next. *See the article* PLOUGHING.

RIDGES, *in a Horſe's Mouth*, are wrinkles or riſings of fleſh in the roof of the mouth, running acroſs from one ſide of the jaw to the other, with furrows between them.

RIDGELING, the male of any beaſt that has been half caſtrated

RING-BONE, a hard ſwelling on the lower part of the paſtern of a horſe, and generally reaches half round the fore-part. It has its name from the reſemblance to a ring.

It often ariſes from ſtrains, &c. and, when behind, from putting young horſes too early upon their haunches; for in that attitude a horſe throws his whole weight as much, if not more, upon his paſterns, than on his hocks.

When it appears diſtinctly round the paſtern, and does not run downwards toward the coronet, ſo as to affect the coffin-joint, it is eaſily cured; but if it takes its origin from ſome ſtrain or defect in the joint originally, or if a callofity is found under the round ligament that covers that joint, the cure is generally dubious, and ſometimes impracticable; as it is apt to turn to a quittor, and in the end to form an ulcer upon the hoof.

The ring-bones, that appear on colts and young horſes, will often inſenſibly wear off of themſelves, without the help of any application; but when the ſubſtance remains, there needs no other remedy beſides bliſtering, unleſs when by long continuance it is grown to an obſtinate hardneſs, and then it may require both bliſtering and firing.

To fire a ring-bone ſucceſsfully, let the operation be performed with a thinner inſtrument than the common one, and let the lines or razes be made not above a quarter of an inch diſtant, croſſing them obliquely, ſomewhat like a chain; apply a mild bliſter over all, and when quite dried up, the rupture plaiſter; and then turn the horſe to graſs for ſome time. *Bartlet's Farriery*, *page* 264.

RIPPLING *of Flax*, the operation of taking off the ſeed from the flax by drawing it through a ripple, or large comb. *See the article* FLAX.

RISING, yeaſt, or barm.

RIVER, a current, or ſtream of freſh water flowing in a bed or channel, from its ſource into the ſea.

RIVULET, a little river or ſmall ſtream of water.

ROD, a meaſure in length, conſiſting of ſixteen feet and a half.

ROLLER, a large piece of wood turning on its axis, and drawn over the ſurface of the ground to break the ſmall clods, and render it ſmooth and even.

Spiky ROLLER. *See* SPIKY ROLLER.

ROLLING, the operation of drawing a roller over the ſurface of the ground.

" Rolling, as well as ploughing and harrowing, ſays Mr. Clarke, if admitted in the culture of fallow-lands, would, I preſume, much facilitate eradicating of weeds,

and

and promote the prolific capacity; for it often happens, that after land has been ploughed and worked with the great harrow, &c. there ſtill are graſs and weeds remaining, that will the next ploughing cauſe the furrows to be ropy, and then much labour and time is required to make it to the mind of the judicious huſbandman, which rolling in the following order will be found to elude.

"Thus, when the land has been once ploughed, bracked, and harrowed, immediately give it a double rolling with a ſtone cylinder about four feet long and three feet radius, which, with its furniture, is a roller about one ton weight: the preſſure of ſuch roller, when there is little moiſture in the land, fixes it ſo much, that no weeds nor graſs can vegetate; next, in about a month after, put in manure by another ploughing, viz. dung or compoſt, whereof dung is the major part; but lime is at this time very improper, as it reſiſts putrefaction: then give the land a ſtroke with the great harrow, and roll it as before: this puts the manure, ſoil, and juices in contact; by which, together with the vivifying heat of the ſun, (that muſt be greater on rolled land than on looſe, rough, unſteady particles of earth, becauſe it thereby becomes quieſcent, and the ſurface acquires a kind of poliſh) fermentation and putrefaction muſt be ardently excited.

"That theſe are ſalubrious and moſt powerful agents in the fertilizing of land, by looſening the compaſſes, and ſetting at liberty the more ſubtile parts of the manure and ſoil, and generating that ſort of air which is found ſo neceſſary to animal as well as vegetable life, none converſant in theſe matters can make the leaſt doubt.

"Now, indeed, may a quantity of quick-lime be applied to great advantage, by being ſpread on the ſurface; for the weeds that are harrowed up, will not only ſoon be diſſolved by it, and converted into nouriſhment for vegetables; but the very principle of vegetation, which is going off in exhalations by the effervescence within, is by it abſorbed, and retained for the nutrition of the crop, which it will communicate when it is ploughed in; and that may be done about fourteen or twenty days after, ſooner or later, as the weather anſwers, or the experimentor ſees it neceſſary: and if it is a ſoil fit to grow turneps, and the ſeaſon proper, the ſeed may be ſown immediately, either in the drill or common way; but the drill, on many accounts, in ſowing turneps, deſerves prece lency; or, if it is to be winter corn, one ploughing more, which is the third only, makes it in fine order for the ſeed.

"The utility of rolling does not end here neither; for to roll wheat, rye, barley, &c. with a roller about twice the length, and half the weight of the one above deſcribed, may be advantageous, as it preſſes down the ſoil, that has been raiſed by the froſts, about the minute ramifications of the attracting ducts, and augments the quantity of mould upon them by breaking the little lumps of ſoil, which, indeed, were very ſerviceable in winter, by affording ſhelter, but in ſpring will ſtill be of greater uſe, by ſuch imminution, in filling up the fiſſures, and preventing, in a great meaſure, the ill effects droughts have on light ſoils, by retaining and filtering rain water; whereby the ſoil imbibes whatever is nutritive, what is ſuperfluous of the ſimple fluid only eſcapes.

"Theſe are ſome of the many advantages rolling produces in agriculture; notwithſtanding which, it amounts to more than mere conjecture, that in general rolling corn may do more damage than it can do good, if ſuch as the following cautions be not carefully attended to, viz. Never to roll corn but in dry, freſh weather; by no means uſe heavy rollers, nor roll too early, i. e. before the blades be pretty ſtrong, for the wounds that the blades may receive, the roots, being then tender, will be unable ever to recover; nor too late, i. e. when the ſtalks are hardened and grown any height, for the roller will break them, which injury hardly can be repaired, and the crop is thereby hurt; that none but light lands are proper to be rolled, and thoſe only which have been manured that or the preceding year with dung: in ſhort, none but rich, light ſoils, in general, can be improved by rolling; for in poor lands it oppoſes the moſt active primogeneous agents, and undoes all that has been done for the crop by ploughing, &c.

"Thus the ſoil, the condition, the growth of the corn, the weather, and the weight of the roller, are all to be moſt ſcrupulouſly regarded: when all coincide, the advantages of rolling will be great; but when they do not, the diſadvantages may be inſuperable,

"Rolling, then, is neither the leaſt critical, nor moſt inſignificant piece of the huſbandman's profeſſion; therefore ought not to be performed at random and without circumſpection. *Muſeum Ruſticum, vol.* IV. *p.* 5.

Rolling is alſo of uſe to land in graſs, by preſſing down mole-hills, &c. It alſo makes the graſs tiller, and grow thicker.

There is a ſort of land, which, when clover is ſown upon it, throws out the young plants after a froſt. Rolling in the beginning of winter, and immediately after the froſt is gone, will, in ſome meaſure, prevent this. The firſt rolling hinders the froſt from penetrating ſo deep as it would otherwiſe do; and the ſecond makes the land firm, after having been looſened by the change from froſt to open weather.

ROOD, a quantity of land equal to forty ſquare poles or perches, that is, a quarter of an acre.

ROOK, a well-known bird, reſembling a crow; but feeds on grain, inſects, &c.

Great care ſhould be taken to guard againſt theſe miſchievous birds at the time when the wheat is juſt ſhooting up; for they perceive its ſhooting much ſooner than the farmer can, and are led by the ſhoot to pick it up. They muſt, therefore, be carefully kept off the ground about a week or ten days after this ſeaſon; for at the end of that time the blade will be grown up, and the grain ſo exhauſted of its ſubſtance, that they will not give themſelves any trouble about ſtealing it. They never moleſt the wheat which is ſown about Michaelmas; becauſe ſo much grain of the late harveſt then lies ſcattered about the fields, that they find it much eaſier to pick up that, than to ſearch for corn under ground in new-ſown lands. They do moſt harm when the ſnow is firſt going off from the green wheat, towards the end of winter; for having been pinched for food during that ſeaſon, they then greedily pluck up the young plants, in order to come at the remainder of the ſeeds ſtill adhering to their roots; and are greatly aſſiſted in this by the looſe ſtate of the earth at that time.

Among the many contrivances to frighten them away, ſuch as feathers ſtuck up, the limbs of rooks ſcattered about the ground, dead rooks hung on ſticks, the gun, a boy to halloo and throw his hat, or to toſs a dead rook up in the air, Mr. Tull ſays he found this laſt to be the moſt effectual. They will immediately quit their uſual places of abode, if the earth is turned up around the trees, in

which

which they have built their neſts, and will not return to them till the graſs is grown again; as was lately experienced in the repairing of Fountain-court in the Temple: Mr. Liſle aſſures us, that the taking down of their neſts, with their young ones in them, and burning under the trees they were built in, will effectually make all the old ones deſert that place. However, it has been doubted, and perhaps with reaſon, whether they do not, upon the whole, compenſate pretty fully, for the miſchief they do to corn, by deſtroying vaſt quantities of grubs, worms, and other pernicious inſects, in the ſpring: as crows are alſo of ſervice in the neighbourhood of populous towns, by devouring a great deal of carrion.

It is a common proverbial ſaying of the countrymen, that at whatſoever farm a colony of rooks plant themſelves, and make a rookery, it is a ſign of proſperity to the occupier of that land; and that, on the contrary, their deſerting it, betides misfortunes and poverty: for both which remarks, Mr. Liſle accounts very rationally, by obſerving, that where a man is a good huſbandman to his land, and improves it, the worms, which are a great food to theſe creatures, eſpecially at certain times of the year, multiply, and grow to a much greater bulk and fatneſs, than in a poor neglected ſoil; the ſtrength of land being as diſcernable by the large ſize of worms, as from the growth of plants; and that the grubs or maggots of the beetle kind in particular, on which the rooks feed greatly, as is apparent from their following the plough, in order to pick them up, not only grow fatteſt and largeſt in rich well tilled ground; but that the beetles themſelves, while in their ſtate of flies, always chooſe to lay their eggs in ſuch land as will beſt nouriſh and provide for their young. The contrary to this ſoon happens under a bad huſbandman.

ROOKERY, a nurſery of rooks, or place where they build their neſts.

ROOP, hoarſeneſs.

ROOT, the lower part of a plant, by which it adheres to the earth, and by which it draws its nouriſhment, and tranſmits the juices to the other parts. For the method of clearing land from the roots, *ſee the article* GRUBBING.

ROSIL, or *Roſills*, land neither light nor heavy, being a medium between ſand and clay.

ROT, a diſeaſe incident to ſheep, ariſing frequently from wet ſeaſons, and too moiſt paſture.

"But the rot in ſheep, ſays an ingenious and practical writer, does not always proceed either from moiſture alone, or the nature of the ſoil alone; for all moiſt grounds do not cauſe the rot in ſheep, and there are ſome lands which rot ſheep in wet years only.

"The rot, in fact, ariſes from a certain putrefaction, both in the air, and in the graſs or herbs that uſually grow in ſuch moiſt years: theſe, together with their moiſt food, corrupt their livers, and bring on the diſeaſe.

"It is indeed very difficult to cure this diſorder, unleſs it is attempted before the liver is too much waſted: where there is a convenience of doing it, the beſt remedy is, an immediate removal to ſalt-marſhes; but this is far from being in every farmer's power: I ſhall endeavour therefore, from my own former experience, to ſupply the deficiency.

"In ſuch caſes as theſe, a prevention of the evil is to be recommended to the practice of every rational farmer.

"Some grounds naturally yield a ſoft, ſpungy graſs, which is, more than any other, ſubject to breed the rot in ſheep; I would therefore adviſe, that other cattle be fed in theſe grounds, and the ſheep kept in the drieſt, hardeſt, and healthieſt paſtures.

"I have known land that has kept ſheep in health for many ſucceſſive years, yet afterwards, when the months of May and June have proved wet, a frim and frothy graſs has ſuddenly ſprung up, which, together with the bad air that muſt of courſe follow, has cauſed a rot in the ſheep that were then on it: the evil was obſerved in time, the ſheep were removed to a dry and almoſt barren heath, and in the ſucceeding winter they were foddered with good, dry, ſweet hay, and a great loſs was prevented: this happened to an old friend of mine, ſince dead.

"This unwholeſome graſs is moſt apt to grow in cold land, and in the ſummer-time; and it is a general opinion, and well founded on experience, that if the ſummer does not rot ſheep, the winter will not, the power of the winter alone not being ſtrong enough to begin a rot.

"A very ſenſible writer, whoſe book I have juſt turned to, I mean Mr. Liſle, ſays that broom is very good for the rot; and indeed I have often experienced it; for in a farm I occupied ſome years ago there were ſeveral broom-fields, and I have often obſerved that ſuch of my ſheep as were part of the year fed in them were never infected with the rot, whilſt others in my poſſeſſion had it to a great degree. I profited however by experience, for I took care thenceforward that all my ſheep ſhould, by turns, enjoy the advantages to be derived from their feeding on the young ſhoots of the broom.

"As to what Mr. Liſle ſays, on the authority of Mr. Ray, that the marſh-trefoil will cure the rot, I cannot, from experience, corroborate it: I have heard its efficacy in this diſorder often mentioned, but never yet heard any particular fact related ſo circumſtantially as to induce me to depend on its effects.

"That ſalt is good, I agree with the above gentlemen and Mr. Boyle; and this gives me an opportunity of communicating a receipt which I know to be a good one.

"When you perceive, by the colour of your ſheep's eyes, that the rot has taken them, drive your flock into a barn, a covered fold, or ſome ſuch convenient place: around this place let there be wooden troughs, like mangers, in which you ſhould feed your ſheep with good, dry, clean oats, for forty-eight hours: then have ready ſome bay ſalt finely powdered and ſearced, of which you are to ſprinkle a little among the oats, encreaſing the quantity till it diſguſts the ſheep, and you perceive they fall off their appetites: afterwards, for the two following days, give them again clean oats; and then mix your ſalt with them as before, continuing this proceſs till their eyes have recovered their natural colour, when you will find them perfectly cured; and to be convinced, it will only be neceſſary to kill one or two of the flock.

"To this I ſhall add a receipt for the rot in ſheep, which was communicated to me by a friend, a man of credit and veracity, who ſays he has often tried it with ſucceſs.

"Steep ſome regulus of antimony in ale, adding thereto ſome grains of paradiſe, and a little ſugar to ſweeten it. Of this infuſion ſomewhat leſs than a gill is to be given to every one of your affected ſheep: they are to have two or three doſes, according as they are more or leſs affected by the diſtemper, allowing two days intermiſſion between each doſe."

"This

" This is ſaid, as I have already obſerved, to be a cure almoſt certain.

" I juſt now take notice, that when rain falls in the months of May and June it is apt to cauſe the rot in ſheep: it will be neceſſary to add, that folding them in the above months encreaſes the diſorder; for after having been deprived of their liberty during the whole night, they bite the noxious graſs the more greedily in the morning, having leſs ceremony in their choice of herbs than if they were not folded. This is a matter of ſome conſequence, therefore worthy of being attended to.

" One thing more I muſt, on the authority of Mr. Liſle, communicate to your readers, viz. an obſervation of a Leiceſterſhire farmer; that ſheep, when firſt touched with the rot, will thrive mightily in fatting for ten weeks; but if they are not diſpoſed of when they are come up to a pitch, they will, in ſeven or eight days time, fall away to nothing but ſkin and bone. The ſame farmer obſerved, that he had often had them die in the height of their pitch, in half an hour's time, with twenty-ſeven pounds of tallow in their bellies." *Muſeum Ruſticum, vol.* I. *page* 434.

To this account we ſhall add a receipt communicated to Mr. Mills by a gentleman of Lincolnſhire.

" Steep a handful of rue in a pail of water all night, and at morning put in as much ſalt as will make it bear an egg. Give each ſheep half a pint of this liquor, and repeat it thrice, every other morning.

" A farmer who kept four hundred ſheep tried this receipt in the laſt general rot (about five years ago), and did not loſe any, though his neighbours loſt almoſt all theirs. For the ſake of the experiment, he ſet apart about twenty, and did not give them this drink. Many of theſe were rotten." *Mills's Huſbandry, vol.* III. *p.* 416.

Buck-bean, or marſh-treſoil, is alſo excellent in this diſtemper. *See the article* BUCK-BEAN.

ROUGHINGS, latter-graſs, aftermaths.

ROUP, the name of a filthy diſeaſe in poultry, conſiſting of a boil or ſwelling upon the rump, and is known by the ſtaring, or turning back of the feathers.

The roup, if not ſoon remedied, will corrupt the whole body of the fowl; to prevent which the feathers ſhould be plucked away, the ſwelling laid open, and the matter preſſed out; after which the part is to be waſhed with brine, or ſalt and water.

ROWEL, a kind of iſſue made in horſes for the cure of various diſorders, as inward ſtrains, hard ſwellings, &c.

The operation is performed in the following manner:

A little ſlit being made through the ſkin, about a hand-breadth below the part aggrieved, big enough to put a ſwan's quill in, the ſkin is raiſed from the fleſh, the end of the quill put in, and the ſkin blowed from the fleſh upwards, and all over the ſhoulder; then, the hole being ſtopped with the finger, the part blown is beat with a hazle-ſtick, and the wind ſpread with the hand all over, and then let go; this done, a ſkain of horſe-hair, or red ſarſenet, half the thickneſs of the little finger, is put in a rowelling-needle, ſeven or eight inches long, and the needle is put into the hole, and drawn through again, ſix or ſeven inches higher; then the needle is drawn out, and the two ends of the rowel tied together, anointing it every day, as well as before the putting it in, with ſweet butter and hog's greaſe, and drawing it backwards and forwards in the ſkin, to make the putrid matter diſcharge itſelf more plentifully.

Others, diſliking theſe rowels, as making too large a ſore and ſcar, uſe the French rowel, which is a round piece of ſtiff leather, with a hole in the midſt, laying it flat between the fleſh and ſkin, the hole in the rowel juſt againſt that in the ſkin, ſewing it with a needle and thread drawn through the hole and the ſkin, cleaning it once in two or three days, and then anointing it afreſh.

" The general and abſurd reaſoning of farriers, ſays Mr. Bartlet, on the effects and uſe of rowelling, makes the following obſervations the more neceſſary, as it is too notorious how impertinently they talk on this ſubject: for in ſhort with them, a rowel is to draw off all the bad and corrupt humours from the blood, by a ſort of magic.

" It is neceſſary to obſerve that the matter generally diſcharged by a rowel, is nothing more, than an ouzing from the extremities of the veſſels divided in the making of it; in fact then, it is blood, which loſes its colour, by being ſhed out of the veſſels, the warmth of the part, and its confinement.

" If this is granted, it will evidently appear, that the good effects enſuing this operation, muſt be owing to a gradual depletion, or emptying of the veſſels in general; by which means the ſurchage or load on a particular part, is taken off and removed; and impurities or bad juices (generally called humours) run off with the good, in proportion to their quantity in the blood.

" To imagine particular humours are thus ſeparately, and alone diſcharged from the blood, thro' theſe orifices, is an opinion but too generally received, tho' a very abſurd one; and muſt be very pernicious in its conſequences, from the bad effects it may have in practice; as muſt the ſame reaſoning alſo in regard to purging.

" Thus to lean hide-bound horſes, and thoſe of a dry hot conſtitution, the diſcharge, by depriving the conſtitution of ſo much blood, and fluids, is daily exhauſting the ſtrength of the animal; and may be productive of bad conſequences, by defrauding the conſtitution of a neceſſary fluid.

" But in diſorders from fullneſs, attended with acrimony, or ſharpneſs of the juices, and with defluxions on the eyes, lungs, or any part of conſequence; the gradual diſcharge brought on by theſe means, will contribute to leſſen the fullneſs on the parts affected, and give the veſſels an opportunity of recovering their tone, while evacuating and alterative medicines are doing their office.

" It may be neceſſary however to obſerve, that there is a wonderful communication between the veſſels of the cellular membrane under the ſkin, which remarkably appears, by inflating thoſe of ſheep, calves, &c. by the butchers: hence probably it is that ſome diſorders of this integument, are ſo apparently relieved by iſſues, or rowels, without our having any recourſe to that general depletion of the veſſels we have juſt obſerved, to account for it; and hence alſo may be deduced their utility, ſometimes in draining off any extravaſated fluids, which may lodge between the interſtices of the muſcles, after violent ſtrains of the ſhoulder; alſo in diſcharging ſuch vicious, or ſharp fluids, as are thrown on the membranes, and occaſion thoſe flying pains and lameneſſes, which we find are often removed by this local remedy." *Bartlet's Farriery, page* 220.

ROWEN, *or* ROWET, winter-graſs.

ROWTY, over-rank, too ſtrong.

RUDDLE,

RUDDLE, a ſort of red earth, of a lax texture, and very eaſily reduced to powder. It is found in ſeveral parts of England, eſpecially in Derbyſhire; and is much uſed in marking ſheep.

RUNCHES, charlock when dry and withered.

RUNNEL, pollard wood.

RUNNET, the acid juice found in the ſtomachs of calves, that have fed on nothing but milk, and are killed before the digeſtion is perfect. It alſo ſignifies a liquor made by ſteeping of the ſtomach of a calf in hot water. The latter is the runnet uſed in making cheeſe, &c.

RUNNING-THRUSH, *or* FRUSH, is an impoſthume that ſometimes gathers in a horſe's frog; or a ſcabby and ulcerous diſpoſition, which ſometimes cauſes it to fall off.

When this diſcharge is natural the feet ſhould be kept clean, but no drying waſhes made uſe of, it being thought as unſafe to repel ſome of theſe diſcharges, as to cure ſome ſweaty feet.

When an impoſthume, or gathering appears, the ſafeſt way is to pare out the hard part of the frog, or whatever appears rotten; and waſh the bottom of the foot two or three times a day with old chamberlye; this is the ſafeſt and beſt way of treating them. But when a horſe has been neglected, and there is a ſtrong flux to the part, it is apt to degenerate into a canker, to prevent which, uſe the following:

Take ſpirit of wine and vinegar, of each two ounces, tincture of myrrh, and aloes one ounce; Ægyptiacum half an ounce; mix together.

Bathe the thruſh with this, wherever there appears a more than ordinary moiſture, and lay over the ulcer a little tow dipped in the ſame. The purges and diuretics recommended in the greaſe, ſhould be given at this time, to prevent the inconveniencies that the drying up theſe diſcharges frequently occaſion. *See the article* CANKER. *Bartlet's Farriery, page* 312.

RUNT, a name given to the ſmall black cattle brought out of Wales and Scotland.

RUNT, is alſo an epithet applied to ſeveral ſpecies of pigeons; as the Leghorn, Spaniſh, and Frieſland runt, &c.

The Leghorn runt is a ſtately large pigeon, ſeven inches or better in the legs, cloſe feathered and faſt-fleſhed, extremely broad-breaſted, and very ſhort in the back. He carries his tail, when he walks, ſomewhat turned up like a duck's; his neck is longer than any other pigeon's, and he carries it bending like a gooſe or ſwan. He is gooſe-headed, and his eye lies hollow in his head, with a thin ſkin round it, like that of the Dutch tumbler. His beak is very ſhort for ſo large a bird, and has a ſmall wattle on it, and the upper chap falls a little over. It is a very valuable pigeon, but is tender, and requires care.

The Spaniſh runt is the longeſt-bodied of all the pigeons; it is ſhort-legged and looſe-feathered, and does not walk ſo upright as the Leghorn runt. Theſe are of a great variety of colours, but are apt to have accidents in ſitting, from their ſitting too heavy, and often breaking their eggs.

The Frieſland runt is a large pigeon, and has all its feathers reverted, or looking as if placed the wrong way.

The Roman runt is a pigeon of the ſame general make with the common kind, but ſo large and heavy that it can hardly fly.

The Smyrna runt is middle-ſized, and is feather-footed, and that to ſuch a degree ſometimes, as to look as if there were wings upon the foot; the feathers of theſe are ſometimes four or five inches long, and often pull the eggs and young out of the neſts. The common runt is the common blue pigeon kept for the table, and known to every body. *Moore's Columbarian.*

RUPTURE, a preternatural eruption of the guts or caul.

In regard to ruptures, though they are generally divided into particular claſſes, we ſhall only obſerve, that by violent efforts of the horſe, or other accidents, the guts or caul may be forced between the muſcles of the belly at the navel, and thro' the rings of the muſcles into the ſcrotum or cod. The ſwellings are generally about the ſize of a man's fiſt, ſometimes much larger, deſcending to the very hock; they are frequently ſoft, and yield to the preſſure of the hand, when they will return into the cavity of the belly with a rumbling noiſe; and in moſt the vacuity may be felt, through which they paſſed.

On their firſt appearance, endeavours ſhould be made to return them by the hand; but if the ſwelling ſhould be hard and painful, in order to relieve the ſtricture, and relax the parts, through which the gut or caul has paſſed, let a large quantity of blood be immediately taken away, and the part fomented twice or thrice a day, applying over it a poultice made with oatmeal, oil and vinegar, which ſhould be continued till the ſwelling grows ſoft and eaſier, or the gut is returned. In the mean time it would be proper to throw up emollient oily glyſters twice a day, and to let the horſe's chief diet be boiled barley, ſcalded malt, or bran.

Should the ſwelling afterwards return, we apprehend the reſtringent applications uſually recommended on theſe occaſions, will avail little without a ſuſpenſory bandage; ſo that an ingenious mechanic in that art is chiefly to be relied on, for any future aſſiſtance; though it has been obſerved, that with moderate feeding, and gentle exerciſe, ſome horſes have continued to be very uſeful under this complaint. *Bartlet's Farriery, page* 334.

RUSH, the name of a well known plant, too common in wet lands.

Ruſhes always intimate a good ſoil; and may be deſtroyed by lime, even after it has been ſlaked, by ſea-coal aſhes, and by draining the land.

RUST, a diſtemper incident to corn, and generally called mildew. *See the article* MILDEW.

RYE, a ſpecies of corn greatly cultivated in the northern parts of England.

Mr. Miller is of opinion that all the rye ſown in England is of the ſame ſpecies, though diſtinguiſhed by farmers into two varieties of winter and ſpring rye, as he has not been able, by the moſt ſedulous experience, to find any difference.

The winter rye, which has the largeſt grain, is what the generality of farmers cultivate. It is uſually ſown in autumn, or at the ſame time as wheat; and in many of our northern countries, as well as in Wales, they are often mixed and ſown together; tho' as Mr. Miller rightly obſerves, this muſt be very bad huſbandry, becauſe the rye will always ripen ſooner than the wheat; ſo that if the latter be ſuffered to ſtand till fully ripe, the grain of the former will ſhed; nor can this be practiſed where the people are not accuſtomed to eat rye-bread: for though ſome account it good when mixed, it is ſo very clammy that

few who have been uſed to wheaten bread will ever reliſh it.

Rye is generally ſown on poor, lime-ſtone, dry, gravelly, or ſandy ſoils, where wheat will not thrive, and in ſuch places it does very well. The ground ſhould be dry when it is ſown: for if much rain falls, even after the ſowing, before the rye is come up, it often rots in the earth. It indeed riſes in a much ſhorter time than wheat.

When ſown upon light land, it ripens much earlier than a cold ſtiff ground, and by continuing to ſow it in ſuch a ſoil during two or three years, it will be forwarded ſo much as to ripen a month earlier than that which has been long raiſed upon ſtrong cold ground. For this reaſon, thoſe who are obliged to ſow rye toward ſpring, generally provide themſelves with this early ſeed. A little ſprinkling of dung or mud, though it be but half the quantity commonly uſed for other corn land, will, if laid upon the rye ground, greatly advance the crop. The uſual allowance is two buſhels of ſeed to a ſtatute acre, or, if it be new broke up ground, or land ſubject to worms, about a peck more; and the produce commonly is about twenty buſhels upon an acre.

In the ſummer of the year 1699, which was uncommonly dry, Mr. Mortimer reckoned ninety grains apiece in ſeveral ears of rye.

The ſmall rye may be ſown in the ſpring, about the ſame time as oats, and uſually ripens as ſoon as the other ſort: but if the ſeaſon prove wet, it is apt to run much to ſtraw, and the grain is generally lighter than the other. The chief uſe of this ſort is to re-ſow lands where the autumnal crop has failed.

This corn is ripe when its ſtraw turns yellow, its ear hangs, and its grain is hard. It is not very apt to ſhed; and therefore, if it be weedy (though this ought never to be the caſe with any corn) it ſhould be let lie upon the ground, or gavel, as ſome call it, a week or ten days after it is cut, if the weeds do not dry ſooner, before it be bound up; for otherwiſe thoſe weeds will give in the barn, make the rye not thraſh well, and render it muſty. But as this grain will grow in the ear ſooner than any other, if it be wet, particular care muſt be taken, eſpecially if rain comes on, to turn it at leaſt once in two or three days, and lay the ears upon the ſtubble, as high above the ground as can be. This will help to preſerve it from hurtful moiſture: but if it be cut in perfectly dry weather, and without weeds, it may be houſed as it is reaped.

The general uſe of rye is for bread, either alone, or mixed with wheat, in which ſtate it is called meſlin corn. It alſo yields a ſtrong ſpirit when diſtilled; and, if ſowed only for dreſſing of land, is of vaſt ſervice to the ground where it is plowed in green and ſucculent. The truly worthy, and reverend Dr. Eliot informs us, that he has not only been told, but knows by his own obſervation, that if rye be ſowed ſucceſſively every year upon the ſame land, both the crop and the land will be greatly improved; inſomuch that ſome grounds which would yield but five buſhels to the acre at firſt have, in time, afforded a crop of fifteen buſhels to the acre, without the charge of dung, or any manure. But it ſhould be remembered that the land ſown by Dr. Eliot, was newly broke up.

This plant is likewiſe ſown in autumn to great advantage, purpoſely for green feed for cattle, particularly for ewes and lambs in the ſpring, before there is plenty of graſs. When this is intended, the rye ſhould be ſown early, that it may have ſtrength to furniſh early fodder. In this light, it ſupplies the want of turnips where they have failed, or where their ſeaſon is over: ſo that, in ſuch caſes, it is very good huſbandry to ſow the land with rye, eſpecially where there are flocks of ſheep, which cannot be well ſupported without green food early in the ſpring. The farmer who has many ſheep ſhould conſider, that turnips are always a very precarious crop; and therefore he ſhould, beſide ſowing ſome places with cole-ſeed, in order to have green fodder, ſow rye in others, to guard againſt accidents. If ſome of the ground ſowed late with turnips, which have failed, be ſown in the autumn with rye, he will find it turn to good account. To have green fodder for cattle in April, which is the ſcarceſt time of all the year, ſome ſplit the ridges of their wheat-ſtubble, and ſow them with rye, allowing about a buſhel to an acre, which they harrow in, and feed about April, or when they want it; and in May they plough it up for a fallow.

RYE-GRASS. *See the article* RAY-GRASS.

SAF

SAF

SAFFRON, a genus of plants with narrow graſs-like leaves, which have a white line running along the middle: the ſtalk is ſhort and undivided, and bears on the top a purpliſh blue flower, deeply cut into ſegments: in the middle of the flower ariſes, among the ſtamina, a whitiſh piſtil, divided at the top into three chives or fleſhy filaments, the lower part of which is ſlender and pale coloured, the upper broader, of a deep orange red, and very finely indented about the ſides: theſe fiiaments, carefully picked, and preſſed together into cakes, are the ſaffron of the ſhops. The plant is perennial, and flowers in autumn.

As ſaffron grows at preſent moſt plentifully in Cambridgeſhire, and has grown formerly in ſeveral other counties of England, the method of culture does not, I believe, vary much in any of them; and therefore I judge it ſufficient to ſet down here the obſervations which I employed proper perſons, in different ſeaſons to make, in the years 1723, 1724, 1725, and 1728, up and down all that large tract of ground that lies between Saffron-Walden and Cambridge, in a circle of about ten miles diameter.

In that county ſaffron has moſt been cultivated; and therefore it may reaſonably be expected, that the inhabitants thereof are more thoroughly acquainted with it than they are any where elſe.

I ſhall begin with the choice and preparation of the ground: the greateſt part of the tract already mentioned is an open level country, with few incloſures; and the cuſtom there is, as in moſt other places, to crop two years, and let the land lie fallow the third. Saffron is always planted upon fallow ground, and, all other things being alike, they prefer that which has borne barley the year before.

The ſaffron grounds are ſeldom above three acres, or leſs than one; and in chooſing, the principal thing they have regard to is, that they be well expoſed, the ſoil not poor, nor a very ſtiff clay, but temperate dry mould, ſuch as commonly lies upon chalk, and is of an hazel-colour; though, if every thing elſe anſwers, the colour of the mould is pretty much neglected.

The ground being made choice of about Lady-day, or the beginning of April, it muſt be carefully plowed, the furrows being drawn much cloſer together, and deeper, if the ſoil will allow it, than it is done for any kind of corn; and, accordingly, the charge is better.

About five weeks after, during any time in the month of May, they lay between twenty and thirty loads of dung upon each acre; and, having ſpread it with great care, they plow it in as before; the ſhorteſt rotten dung is the beſt; and the farmers, who have the conveniency of making it, ſpare no pains to make it good, being ſure of a proportionable price for it. About Midſummer they plow a third time, and, between every ſixteen feet and a half or pole in breadth, they leave a broad furrow or trench, which ſerves both as a boundary to the ſeveral parcels, when there are ſeveral proprietors to one incloſure, and to throw the weeds in at the proper ſeaſon.

To this head likewiſe belongs the fencing of the grounds, becauſe moſt commonly, though not always, that is done before they plant. The fences conſiſt of what they call dead hedges, or hurdles, to keep out not only cattle of all ſorts, but eſpecially hares, which would otherwiſe feed on the ſaffron leaves during the winter.

About the weather we need only obſerve, that the hotteſt ſummers are certainly the beſt: and therewith, if there be gentle ſhowers from time to time, they can hardly miſs of a plentiful crop, if the extreme cold, ſnow, or rain of the foregoing winter have not prejudiced the heads.

The next general part of the culture of ſaffron, is planting or ſetting the roots: the only inſtrument uſed for which is a narrow ſpade, commonly termed a ſpit-ſhovel.

The time of planting is commonly in July, a little ſooner or later, according as the weather anſwers. The method is this: one man with his ſpit-ſhovel ariſes between three and four inches of earth, and throws it before him about ſix or more inches; two perſons, generally women, following with heads, place them in the fartheſt edge of the trench he makes, at three inches diſtance from each other, or thereabouts: as ſoon as the digger or ſpitter has gone once the breadth of the ridge, he begins again at the other ſide, and digging, as before, covers the roots laſt ſet, and makes the ſame room for the ſetters to place a new row, at the ſame diſtance from the firſt as they are from one another: thus they go on, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave ſome part of the firſt ſtratum of earth untouched, to lie under the roots; and, in ſetting, to place the roots directly upon their bottom.

What ſort of roots are to be preferred, ſhall be ſhewn under the fourth head; but it muſt be obſerved in this place, that formerly, when roots were very dear, they did not plant them ſo thick as they do now: and that they have always ſome regard to the ſize of the roots, placing the largeſt at a greater diſtance than the ſmaller ones.

The quantity of roots, planted in an acre, is generally about ſixteen quarters, or one hundred and twenty-eight

buſhels, which according to the diſtances left between them, as before aſſigned, and ſuppoſing all to be an inch in diameter one with another, ought to amount to three hundred and ninety-two thouſand and forty in number.

From the time that the roots are planted, till about the beginning of September, or ſometimes later, there is no more labour about them; but as they then begin to ſpire, and are ready to ſhew themſelves above ground, which is known by digging a few out of the earth, the ground muſt be carefully pared with a ſharp hoe, and the weeds, &c. raked into the furrows, otherwiſe they would hinder the growth of the plants.

In ſome time after appear the ſaffron flowers; and this leads us to the third branch of our preſent method. The flowers are gathered as well before as after they are full blown; and the moſt proper time for this is early in the morning. The owners of the ſaffron get together a ſufficient number of hands, who place themſelves in different parts of the field, pull off the whole flowers, and throw handful by handful into a baſket, and ſo continue till all the flowers are gathered, which happens commonly about ten or eleven o'clock. Having then carried home all they have got, they immediately ſpread them upon a large table, and fall to picking out the filamenta ſtyli, or chives, and together with them a pretty long proportion of the ſtylus itſelf, or ſtring to which they are joined; the reſt of the flower they throw away as uſeleſs. The next morning they return into the field again, whether it be wet or dry, weather; and ſo on daily, even on Sundays, till the whole crop be gathered.

The chives being all picked out of the flowers, the next labour about them is to dry them on the kiln. The kiln is built upon a thick plank, that it may be removed from place to place, ſupported by four ſhort legs: the outſide of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches ſquare at the bottom on the inſide, and twenty-two inches at top; which is likewiſe equal to the perpendicular height of it. On the foreſide is left a hole about eight inches ſquare, and four inches above the plank, through which the fire is put in. Over all the reſt laths are laid pretty thick, cloſe to one another, and nailed to the frame already mentioned; and then are plaiſtered over on both ſides, as are alſo the planks at bottom very thick, to ſerve for an hearth. Over the mouth or wideſt part goes an hair-cloth, fixed to the ſides of the kiln; and likewiſe to two rollers, or moveable pieces of wood, which are turned by wedges or ſcrews, in order to ſtretch the cloth. Inſtead of the hair-cloth, many people now uſe a net work, or iron wire, with which it is obſerved that the ſaffron dries ſooner and with a leſs quantity of fuel: but the difficulty in preſerving the ſaffron from burning, makes the hair-cloth be preferred by the niceſt judges in drying.

The kiln is placed in a light part of the houſe; and they begin by laying five or ſix ſheets of white paper on the hair-cloth, upon which they ſpread the wet ſaffron, between two and three inches thick: this they cover with other ſheets of paper, and over theſe they lay a coarſe blanket five or ſix times doubled; or, inſtead thereof a canvas pillow filled with ſtraw; and, after the fire has been lighted for ſome time, the whole is covered with a board, having a large weight apon it.

At firſt they give it a pretty ſtrong heat, to make the chives ſweat, as their expreſſion is; and in this, if they do not uſe a great deal of care, they are in danger of ſcorching and ſo of ſpoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the ſaffron off from that which lies next it; raiſing, at the ſame time, the edges of the cake with a knife; then, laying on the paper again, they ſlide in another board between the hair-cloth and under papers, and turn both papers and ſaffron upſide down; afterwards covering them, as above.

This ſame heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it: then they cover it, and lay on the weight, as before. If nothing happens amiſs during theſe firſt two hours, they reckon the danger to be over: for they have nothing more to do, but to keep a gentle fire, and to turn their cakes every half-hour, till thoroughly dry: for the doing of which as it ought, there are required full twenty-four hours.

In drying the layer of plump chives they uſe nothing more, but towards the latter end of the crop, when theſe come to be ſmaller, they ſprinkle the cake with a little ſmall beer, to make it ſweat as it ought; and they begin now to think, that uſing two linnen cloths next the cake, inſtead of two innermoſt papers, may be of ſome advantage in drying: but this practice is followed as yet but by few.

Their fire may be made of any kind of fewel; but that which ſmokes the leaſt is beſt; and charcoal, for that reaſon, is preferred to any other.

What quantity of ſaffron a firſt crop will produce, is very uncertain; ſometimes five or ſix pounds of wet chives are got from one root; ſometimes not above one or two, and ſometimes not enough to make it worth while to gather and dry it. But this is always to be obſerved, that about five pounds of wet ſaffron go to make one pound of dry, for the firſt three weeks of the crop; and ſix pounds during the laſt week; and, now the heads are planted very thick, two pounds of dried ſaffron may, at a medium, be allowed to an acre for the firſt crop, and twenty-four pounds for the two remaining; the third being conſiderably larger than the ſecond.

In order to obtain theſe, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the ſame manner as before ſet down, without the addition of any thing new; except that they let cattle into the field, after the leaves are decayed, to feed upon the weeds; or, perhaps, mow them for the ſame uſe.

About the Midſummer after the third crop is gathered, the roots muſt all be taken up and tranſplanted: the management requiſite for which is the fourth thing to be treated of. To take up the ſaffron heads, or break up the ground, as the term is, they ſometimes plough it, ſometimes uſe a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over; during all which time of ploughing or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads, as they are turned up.

They are next to be carried to the houſe in ſacks, and there cleaned and raiſed: this labour conſiſts in cleaning the roots thoroughly from earth, and from the remains of old roots, old involucra, and excreſcences; and thus they become fit to be planted in new ground immediately, or to be kept for ſome time, without danger of ſpoiling.

The

The quantity of roots taken up, in proportion to thoſe which were planted, is uncertain; but, at a medium, it may be ſaid, that, allowing for all the accidents which happen to them in the ground, and in breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are ſure to chuſe for their own uſe the largeſt, plumpeſt, and fatteſt roots; but do leaſt of all approve the longeſt-pointed ones, which they call ſpickets, or ſpickards; for very ſmall round or flat roots are ſometimes obſerved to flower. This is the whole culture of ſaffron in the county abovementioned; and we have only now to conſider the charges and profits which may be ſuppoſed, one year with another, to attend that branch of agriculture; and of theſe I have drawn up the following computation for one acre of ground, according to the price of labour in this county.

	l.	s.	d.
Rent for three years	3	00	0
Ploughing for three years	0	18	0
Dunging	3	12	0
Hedging	1	16	0
Spitting and ſetting the heads	1	12	0
Weeding or paring the ground	1	04	0
Gathering and picking the flowers	6	10	0
Drying the flowers	1	06	0
Inſtruments of labour for three years, with the kiln, about	0	10	0
Plowing the ground once, and harrowing twice	0	12	0
Gathering the ſaffron heads	1	00	0
Raiſing the heads	1	12	0
Total charge	23	12	0

This calculation is made upon ſuppoſition, than an acre of ground yields twenty-ſix pounds of net ſaffron in three years; which I ſtated only as a mean quantity between the greateſt and the leaſt; and therefore the price of ſaffron muſt be judged accordingly; which I think cannot be done better than by fixing it at thirty ſhillings per pound; ſince, in plentiful years, it is ſold at twenty, and is ſometimes worth three or four pounds: at this rate, twenty-ſix pounds of ſaffron are worth thirty-nine pounds: and the net profits of an acre of ground, producing ſaffron, will, in three years, amount to fifteen pounds thirteen ſhillings, or about five pounds four ſhillings yearly.

This, I ſay, may be reckoned the net profit of an acre of ſaffron, ſuppoſing that all the labour were to be hired for ready money: but, as the planter and family do a conſiderable part of the work themſelves, ſome of this expence is ſaved: that is, by planting ſaffron, he may not only reaſonably expect clear about five pounds yearly per acre, but alſo to maintain himſelf and family for ſome part of each year: and it is upon this ſuppoſition only, that the reſult of other computations can be ſaid to have any tolerable degree of exactneſs; but the calculations themſelves are undoubtedly very inaccurate.

I have ſaid nothing here concerning the charge in buying, or profits in ſelling the ſaffron heads; becauſe, in many large tracts of ground, theſe muſt at length balance one another, while the quantity of ground planted yearly continues the ſame; which has been pretty much the caſe for ſeveral years paſt. *Philoſophical Tranſactions, Numb.* 405.

SAINTFOIN, *or* SAINFOIN, the name given by the French, and continued by us to a ſpecies of plant, frequently uſed for the food of cattle, either freſh or dried; it is called holy-hay, or wholeſome hay, from its excellent nutritive quality. The ſtalks of the plant are commonly about two feet long, but they grow ſometimes to five or ſix feet, and it has tufts of red flowers of three, four, or five inches in length.

This plant will make a forty times greater increaſe in poor ground than the common turf; and this is owing to its having a long perpendicular root, of that kind, called tap roots, which ſinks to a great depth to attract its nouriſhment. The length of this root is ſcarce to be credited by any but thoſe who have ſeen it; it is frequently drawn out of the ground to the length of twelve or fourteen feet, but it is ſaid to be often thirty feet or more in length.

The farmers have a general opinion, that this plant never ſucceeds well in any land, where there is not an under ſtratum of ſtone, or chalk, or ſome other hard matter, to ſtop its running; but that otherwiſe it ſpends itſelf in root, and comes to nothing above ground. This is an error too groſs to need much refutation. It is certain, that the roots being to plants what the ſtomach and guts are to animals, the more and larger roots any plant has, the more nouriſhment it receives, and the better it thrives.

Saintfoin always ſucceeds where its roots run deep, and the beſt crops of all are produced upon lands where there is no hard under ſoil to obſtruct their paſſage. An under ſoil of clay may kill the plants, by retaining the water, and chilling and rotting their roots.

The long root of ſaintfoin has, near the ſurface, many horizontal roots iſſuing from it, which extend themſelves every way; there are of the ſame kind all the way down, as the roots go, but they grow ſhorter and ſhorter all the way. Any dry land may be made to produce this valuable and uſeful plant, though it be ever ſo poor, but the richeſt and beſt land will produce the beſt crops of it. The beſt way of ſowing it is by drilling; but the earth muſt be very well prepared, and the ſeed well ordered, or elſe very little of it will grow. The heads of theſe ſeeds are ſo large, and their necks ſo weak, that, if they be much more than half an inch deep, they are not able to riſe through the incumbent mould; and, if they are not covered, they will be malted, as the farmers expreſs it; that is, it will ſend out its roots while it lies above-ground, and be killed by the air; and whether the farmer plants bad ſeed that will not grow, or good ſeed that is buried or malted, the event will be the ſame. The ground will be underſtocked with plants. A buſhel of ſeed to an acre of land is full twenty ſeeds to each ſquare foot of land; but, as there is ſome difference in the largeneſs of the ſeeds, there is no abſolute certainty as to this calculation. The worſt ſeaſons for planting are the beginning of winter, and the drought of ſummer; the beſt is the beginning of the ſpring; and it is alſo ſtrongeſt when planted alone, and is not ſown together with corn, as is the practice of ſome farmers. If barley, oats, or any other corn, ſown with the ſaintfoin, happen to be lodged afterwards, it kills the young ſaintfoin. If it be planted with any other corn, it is beſt done by drilling in the horſe-hoeing way; in this caſe it is not much liable to be killed by the lodging of the corn, as the drilled corn ſeldom falls at all, and, when it does, never falls ſo low as the ſown corn.

The

The quantity of ſeed to be drilled upon an acre of land will depend wholly upon the goodneſs of it; for there is ſome ſeed of which not one in ten will ſtrike, whereas in good ſeed not one in twenty will fail. The method of knowing the goodneſs, is, by ſowing a certain number of the ſeeds, and ſeeing how many plants are produced by them. The external ſigns of the ſeeds being good are, that the huſk is of a bright colour, and the kernel plump, of a light grey or blue colour, and ſometimes of a ſhining black. The ſeed may be good, though the huſk be black, as that is owing ſometimes to the letting it receive the wet in the field, not to its being half rotted in the heap.

If the kernel be cut a-croſs, and appear greeniſh and freſh, it is a certain ſign that it is good. If it be of a yellowiſh colour, and friable, and look thin and pitted, they are bad ſigns. The quantity of ſeeds allowed to the acre in the drill way is much leſs than that by ſowing, and is to be computed according to the number of plants that are to be allowed in that ſpace, allowing for the common caſualties. It is not neceſſary to be exact in this calculation, or to ſay whether two, three, or four hundred plants are to be allowed to a ſquare perch; neither is it poſſible to know beforehand the preciſe number of plants that may live out of thoſe that come up; for ſometimes the grub takes them when they have only the two firſt leaves, and the crop is greatly diminiſhed by this means. Four gallons of good ſeed to an acre of land will cover it with plants, when judiciouſly managed.

Single plants of ſaintfoin make the greateſt crops; but the farmers, in general, plant them ſo cloſe, that they ſtarve one another. The ſingle plants always run the deepeſt, and thoſe which do ſo will always draw moſt nouriſhment. The plants which ſtand crowded ſtarve one another, and often die after a few years; but the ſingle ones grow to a vaſt bigneſs, and are every year better and better.

The beſt way to calculate how many plants are to be allowed to a perch, is to compute how much hay each ſingle large plant will produce; for, if kept ſingle, and well cultivated, they will all be large ones. Without culture, theſe plants never arrive at a fourth part of the ſize that they do with it. The hay of a large ſingle cultivated plant will weigh more than half a pound, a hundred and twelve plants upon a ſquare perch, weighing but a quarter of a pound a piece, one with another, amount to two tons to an acre. If ſaintfoin be planted on ſome ſorts of land early in the ſpring and hoed, it will ſometimes produce a crop the following ſummer; in a garden the ſeeds ſown in February will yield plants of two feet high that will flower in the month of June following; and, though March be froſty, the young plants ſeldom ſuffer by it. This ſhews, that this plant is naturally a quick grower; but the farmers uſually plant it on poor or cold land, and give it too little culture, which make it backward, and ſlow of growth with them. The poor land, uſually allotted to this plant, alſo makes it generally yield but one crop a year, but on a rich land it will yield two very good crops annually, with a moderate ſhare of culture and management.

The farmer who expects to make a profit of this plant muſt not expect a good crop the firſt year. Nothing is ſo injurious to ſaintfoin as its ſtanding too thick; if it be ſown ſo thick as to cover the ground the firſt ſummer, the plants will ſtarve one another for ever after; but, if the owner will be content to place them ſo thinly as to have but a ſmall crop the firſt year, they will increaſe prodigiouſly, and every ſucceeding crop will be better and better. When ſaintfoin is well hoed, it will grow as much in a fortnight as it would otherwiſe do in ſix weeks; and this quick growing is of advantage to it every way, not only making the plants large, but of better nouriſhment to the cattle, whether they are eaten green or made into hay.

The proper diſtance to drill this plant for the horſe-hoeing huſbandry is at double rows with eight inch partitions between them, and thirty inch intervals between every two and two. Theſe intervals need only be hoed alternately, leaving every other interval for making the hay on. This method of hoeing is of vaſt advantage, and poor land by means of it will always produce two crops a year. The land is always to be perfectly cleared of graſs before the ſowing the ſaintfoin, and the lumps of earth carefully broken. But no harrowing is to be allowed after it is drilled, for that would bury it; and, it is not proper to roll it at all, unleſs for the ſake of barley, when they are ſown together; and when that is done, it ſhould be with a light roller, and in dry weather. This ſhould be done lengthwiſe of the rows, and as ſoon as it is drilled; if it be not done at this time, it is beſt to ſtay three weeks before it is done, that the necks of the young ſaintfoin may not be broken.

No cattle are to be ſuffered to come in the firſt winter upon the ſaintfoin, after the corn is out, among which it was ſown. Their feet would injure it by treading the ground hard, as much as their mouths by cropping it, and it would never come to good. Sheep ſhould not be ſuffered to come at it, even the following ſummer and winter. One acre of drilled ſaintfoin, conſidering the difference of the quantity and goodneſs of the crop, is worth two acres of ſown ſaintfoin on the ſame land, though the expence of drilling be twenty times leſs than that of ſowing. The firſt winter is the time to lay on manure after the corn is reaped off. Pot-aſhes, or the like, are very proper, and a ſmall quantity of them will do, as there are at this time no other plants to partake of the benefit, but the young crop has it all; and the young plants, being thus made ſtrong at firſt, will continue ſo, and be long the better for it.

It is obſerved, however, that in the drilling and horſe-hoeing-way there is no neceſſity for any manure at all. Some farmers ſow eight or ten buſhels of the ſeed of ſaintfoin to an acre along with their corn, with intent that it ſhould kill all the other weeds; but the conſequence is, that the plants ſtand cloſe, and ſtarve one another, and are no bigger than where the plant grows wild on the hills in Calabria, where it is ſo ſmall and ſeemingly deſpicable a plant, that it ſeems a wonder that any body ſhould be tempted to think of cultivating it: yet, when rightly managed, it ſeems capable of being as uſeful a plant as any in the world. Where theſe plants ſtand ſo thick, they draw out all the nouriſhment from the ground, in a few years, and ſo die, though manured ever ſo carefully. Six or ſeven years ſeems their greateſt duration; whereas, when the ſeed is drilled in, and the plants are horſe-hoed, they will be as ſtrong and vigorous as ever, at thirty years ſtanding.

Some people who have turned their thoughts to huſbandry, have been of opinion, that the cytiſus would ſucceed better with us than the ſaintfoin; it is probable enough that it would grow well; but the labour of ſheering it would, with us, where the pay of ſervants is ſo dear,

run

run away with the greateſt part of the profits of the crop.

Lucerne is another thing which many have thought of introducing among us in the place of ſaintfoin, but it requires ſo much care to ſuit it with a proper ſoil, that, whatever are the profits of it, it never can be ſo general as ſaintfoin. *Tull's Horſe-hoeing Huſbandry.*

Saintfoin, ſays Mr. Duhamel, deſerves the farmer's utmoſt attention, as one of the moſt profitable plants he can cultivate. It will do on almoſt any land; and though it ſucceeds beſt in good ſoils, yet it will grow even on dry barren ſpots, where ſcarce any other graſs can live; provided its roots be not chilled by a cold clay, or other ſubſtance which retains water: and it has this farther advantage, that it may be mowed at different degrees of ripeneſs, with nearly the ſame profit.

1. It may be mowed before it is in bloom, for it is then admirable food for horned cattle; and when cut thus early, it yields a ſecond crop, which makes ample amends for what was loſt by not letting the firſt come to its full growth. This early cutting is likewiſe attended with another benefit, which is, that it purges cattle, in the beginning of the ſummer, and thereby frees them from diſorders occaſioned by the winter's cold, or dry food.

2. If the weather be rainy, the ſaintfoin may be left ſtanding till it is in bloom; when it ſtill is excellent fodder for cows. But care muſt be taken in making it into hay, that the flowers do not drop off, as they are very apt to do: for cattle are ſo fond of theſe flowers, that they often induce them to eat the reſt of the plant.

3. If the rain continues, the ſaintfoin may be left ſtanding till ſome of its ſeeds are formed, and the crop will then be the more plentiful; not only becauſe it will have attained its full growth, but likewiſe becauſe its leaves, being more ſubſtantial, diminiſh leſs in drying. It is not indeed, then, quite ſo ſweet as before; but horſes eat it readily, becauſe they love to feel between their teeth the ſeeds, which now begin to be formed.

Mr. Tull ſays this fodder is ſo excellent, that horſes need no oats when they are fed with it. He affirms that be kept a team of horſes with it a whole year in good plight, without giving them any oats, though they were worked hard all the time. He adds, that he fattened ſheep with it, in leſs time than others which were fed with corn. But the hay of this plant can never be ſo good as when it is cultivated with the horſe-hoe: for in the common huſbandry, it bloſſoms almoſt as ſoon as it is out of the ground.

"If the ſeaſon continues rainy, it may be more adviſable to let the ſaintfoin remain ſtanding, than to run the hazard of having it rot upon the ground: for then the ſeed will ripen, and nearly make up for the loſs of the fodder; not only becauſe it will fetch a good price, but alſo becauſe two buſhels of it will go as far in feeding of horſes, as three buſhels of oats; and cattle in general, as well as poultry, are extremely fond of it.

The firſt of theſe ſorts of ſaintfoin hay, cut before the bloom, is Mr. Tull's virgin hay, which, he ſays, is the beſt beyond compariſon, and has not its equal, in the world, except lucerne. He gives the next place to the ſecond ſort, cut whilſt in bloom, and ſays that an acre of land well cultivated, may yield three tons of this bloſſomed hay: and he eſteems the third ſort, which he calls the full grown, many degrees inferior to either of the former; though it yields a greater crop, becauſe it has grown to its full bulk, and ſhrinks but little in drying.

Even the ſaintfoin that has yielded its ſeed, may be cut down and dried; and when other fodder is ſcarce, this will be better food for horſes and large cattle, than the coarſe hay of flowed meadows, or any kind of ſtraw.

The manner of making ſaintfoin hay is thus directed by Mr. Duhamel.

In a day or two after the ſaintfoin has been mowed, it will be dry on the upper ſide, if the weather be good. The ſwarths, or mowed rows, ſhould then be turned, not ſingly, but two and two together: for by thus turning them in pairs, double the ſpace of ground is left betwixt pair and pair, and this needs but one raking, whereas, if the ſwarths were turned ſingly, that is, all the ſame way, the ground would require as much raking again.

As ſoon as both ſides of the ſwarths are a little dry, they ſhould be made up into ſmall cocks, the ſame day they are turned, if poſſible: for when the ſaintfoin is in cock, a leſs part of it will be expoſed to the injuries of the night, than when it lies ſcattered upon the field. The ſun and dew would exhauſt almoſt all its juices, in this laſt caſe, in leſs than a week's time.

Theſe little cocks of ſaintfoin may be ſafely made into large ones, without waiting for their being ſo thoroughly dry as thoſe of common hay ought to be before they are laid together: becauſe common hay, by ſinking down cloſer, excludes the air neceſſary for keeping it ſweet; ſo that if the weather prevents its being frequently ſtirred and opened, it will heat, turn yellow, and be ſpoiled; whereas ſaintfoin, by admitting the air more freely, becauſe its ſtalks are leſs flexible, will remain much longer without any danger of fermenting.

Saintfoin hay is never better than when it has been dried by the wind only, without the aſſiſtance of the ſun. A little rain, or a miſt, which will turn common hay, clover, and even lucerne, black, will do no hurt to ſaintfoin, which is not really ſpoiled, till it rots upon the field.

If the weather threatens rain, and the ſaintfoin is not yet dry, it may be laid in cocks, without fear of its heating, provided a large baſket, or buſhy faggot, be ſet up in the middle of each cock, where it will ſerve for a vent-hole, through which the ſuperfluous moiſture of the hay will tranſpire.

As ſoon as all danger of its heating is over, theſe cocks ſhould be made into ricks, and thatched. That which is laid up quite dry, will come out of the rick of a green colour: that which has heated much in the rick, will look brown.

It requires ſome experience to know at what degree of ripeneſs it is beſt to cut the ſeeded ſaintfoin; becauſe all its ſeeds do not ripen at the ſame time. Some ears bloſſom before others; every ear begins bloſſoming at its lower part, and continues to blow gradually upward, for many days; ſo that before the flower is gone off at the top, the ſeeds are almoſt filled at the bottom. By this means, if the cutting be deferred till the top ſeeds are quite ripe, the lower, which are the beſt, would ſhed, and be loſt. The beſt time, therefore, to cut it, is when the greateſt part of the ſeed is well filled, the firſt blown ripe, and the laſt blown beginning to be full. The unripe ſeeds will ripen after cutting, and be, in all reſpects, as good as thoſe that were ripe before. Some, for want of obſerving this, have ſuffered their ſaintfoin ſeed to ſtand till all of it has ſhed, and been loſt in cutting.

Saint-

Saintfoin ſhould never be cut in the heat of the day, while the ſun ſhines out; for then much, even of the unripe ſeed, will ſhed in mowing. The right time for this work, is the morning or the evening, when the dew has rendered the plants ſupple.

If the weather is fine and clear, the ſaintfoin will ſoon dry ſufficiently in the ſwarths, without turning them; but if any rain has fallen, and there is a neceſſity for turning them, it ſhould be done very gently, while they are moiſt, and not two ſwarths together, as in the other hay made of ſaintfoin before it has ſeeded. If the ſwarths are turned with the handle of the rake, it is beſt to raiſe up the ear-ſides firſt, and let the ſtub-ſide reſt on the ground in turning: but if it is done with the teeth of the rake, let the ſtub-ſide be lifted up, and the ears reſted on the earth.

If ſaintfoin be cocked at all, the ſooner it is done, the better; becauſe, if the ſwarths are dry, much of the ſeed will be loſt in ſeparating them; the ears being entangled together. When moiſt, the ſeed ſticks faſt in the ear; but when dry, it drops out with the leaſt touch or ſhaking.

There are two ways of threſhing it: the one in the field, the other in the barn. The firſt cannot be done but in very fine weather, and while the ſun ſhines in the middle of the day. The beſt manner of performing this, is to have a large ſheet pegged down to the ground, for two men to threſh on with their flails, while two others bring them freſh ſupplies in a ſmaller ſheet, and two more clear away the hay that has been threſhed. The ſeed is emptied out of the larger ſheet, and riddled through a large ſieve, to ſeparate it from the chaff and broken ſtalks; after which it is put into ſacks, and carried into the barn to be winnowed. Care ſhould be taken not to let the hay get wet, becauſe it would then be ſpoiled.

A very important, and at the ſame time very difficult article, is the keeping of the ſeed that has been threſhed in the field, without having ever been wetted. If it be winnowed immediately, and only a little of it laid amidſt a great heap, or put into a ſack, it will ferment to ſuch a degree, in a few days, that the greateſt part of it will loſe its vegetative quality. During that fermentation, it will be very hot, and ſmell ſour. Spreading it upon a barn floor, though but ſeven or eight inches thick, will anſwer no end, unleſs it be frequently and regularly turned both day and night, until the heating is over: but even this will not make its colour keep ſo bright as that which is well houſed, well dried, and threſhed in the winter. This laſt, laid up unthreſhed, will keep without any danger of ſpoiling, becauſe it does not lie cloſe enough to heat. The beſt way to preſerve the ſeed threſhed in the field, is, to lay a layer of ſtraw upon a barn floor, and upon that a thin layer of ſeed, then another layer of ſtraw, and another layer of ſeed, and ſo on alternately. By this means the ſeed mixing with the ſtraw, will be kept cool, and come out in the ſpring with as green a colour as when it was put in.

The following method is followed in cultivating ſaintfoin in the Iſle of Thanet.

Though the lands in general here are very rich and fruitful, owing to the good tillage, and the quantity of manure they enjoy, yet at ſome diſtance from the ſea, they have land which is very barren and thin by nature; nevertheleſs, even this indifferent land they farm to the greateſt advantage. In theſe ſoils the farmers ſow ſaintfoin or French graſs with great ſucceſs, having ſometimes two loads of hay on an acre.

This graſs thrives beſt in theſe parts, on a thin coat of earth with a chalky bottom; it puſhes its long tap-root deep into the chalk, and extracts thence a nouriſhment, which is out of the reach of almoſt any other plant.

The land muſt always be exceedingly well prepared, before they attempt to put the ſeed in the ground; it has frequent plowings, and every the leaſt appearance of a weed or root of graſs is diligently picked off: graſs in particular is a very great enemy to this plant; without the utmoſt care it ſoon choaks and deſtroys it. They ſow this ſeed in April, either at the beginning, middle, or latter end of the month, according to the ſeaſon: dry weather is beſt, provided it does not long continue: however, a little rain in theſe light ſoils does no great hurt. The quantity of ſeed they allow to an acre is five buſhels; of courſe it is ſown very thick. It does not lie any great length of time in the ground: when it is come up, they careſully hoe and weed it, to keep down the roguery and graſs: this puts the plants forward, and makes them ſo vigorous and ſtrong, that they will of themſelves keep down the graſs, eſpecially in theſe chalky bottoms, where graſs does not thrive well, and is not apt to coat land with turf.

Saintfoin uſed formerly to hold good in theſe parts for twenty years together, but it does not now of late years laſt ſo long: this is probably owing to their want of care in chuſing their ſeed, which ſurprizes me, conſidering what good farmers they in general are. They get, it is true, when they can, the beſt ſeed the iſland affords: but it would certainly be a much better way were they now and then to procure ſome of a finer growth from France: for it was from that country, as far as I can underſtand, it firſt came hither, about the latter end of Charles the Second's reign; and I do not hear from the inhabitants that they ever remember the importing any more ſince.

The climate of France is more natural to it; of courſe the ſeed comes to greater perfection there, whilſt, on the contrary, in England, that, as well as many other crops, is apt to degenerate after a certain number of years.

Where this crop takes, it is very advantageous to the farmer; it yields him for many years plenty of excellent fodder, and that upon land which would otherwiſe, perhaps, ſcarcely yield him any profit at all; and beſides all this, when the ſaintfoin begins to fail, if proper care is taken, the land when broke up will be found greatly refreſhed, and in a better condition to bear tillage and a ſucceſſion of other crops.

The farmers here, when they intend breaking up a ſaintfoin lay, feed it the laſt three or four years: mowing it at this time, they think, hurts and exhauſts the land too much; and beſides, the dung and urine of the cattle are of great ſervice.

They obſerve here, as well as in other places where ſaintfoin is cultivated, that after land has been once ſown with it, it will not for ſome years, to any advantage, bear ſaintfoin again. *Muſeum Ruſticum*, *vol.* I *page* 109.

The reader is obliged to Mr. Holdway, an old experienced farmer at Marlborough in Wiltſhire, for the following account of cultivating ſaintfoin in that county.

" About one hundred years ago, ſays he, the culture of ſaintfoin was firſt introduced into Wiltſhire, and was ſoon preferred

preferred to clover graſs; and there was indeed ſome reaſon for this preference, for it thrives much better, and yields a much larger encreaſe, on poor hungry ſoils, than clover can do.

"Another very good reaſon may be aſſigned why ſaintfoin was ſo well received. The ſowing it at all was conſidered as a new huſbandry, and the timorous farmers were very unwilling to hazard the trial of any new method on lands which would any other way yield them any conſiderable advantage: it was chiefly in corners of fields, of very little uſe to the farmer, that this paſture was firſt tried, and that on poor lands, as, ſhould it not have ſucceeded, the only loſs would have been the ſeed; yet many occupiers of land would not, at firſt, hazard even this trifling loſs.

"But the ſentiments of theſe farmers were ſoon altered in this matter: clover wears out in a few years, whereas many, who ſowed ſaintfoin on poor land not worth above ſix ſhillings an acre, found their land ſo much improved as to be very ſpedily worth thirty ſhillings the acre, and at the end of twenty years it continued yet in good proof.

"In fact, it will thrive, and be a very conſiderable improvement, on the pooreſt, and ſeemingly on the barreneſt land; but it muſt be remembred, that ſheer and ſlight ſands, and all clays, and other cold and wet ſoils, are to be excepted: on rich land the weeds ſoon deſtroy it. Beſides, as it ſends its roots very deep in ſearch of nouriſhment, the longer it occupies the land, the more good it does it; whereas this is far from being the caſe with ſhallow-rooting plants.

"A ſaintfoin lay may at any time be broke up, when it will be ſure to yield ſeveral good crops of corn, and may afterwards again with good ſucceſs be ſown with ſaintfoin; and one principal reaſon why it thrives ſo well on poor lands muſt be the length of the roots by which it is enabled to reſiſt the parching heat of the ſun better than moſt other graſſes are.

"One thing I muſt notify, which is, that I am by long experience convinced that the land cannot be made too fine for ſaintfoin; it thrives the better for it, and is the more certain to take.

"I have often, with very good ſucceſs, ſown it with oats and barley in the manner clover is ſown, the proportion much about equal to the grain it is ſown with; for as the ſeed of ſaintfoin is much larger and lighter than clover ſeed, of courſe a larger quantity ſhould be ſown: it is much beſt for the plants to come up thick; the ground is thereby ſooner ſtocked, and the weeds are eaſier kept under.

"Some in this county have ſown it in rows with intervals, to afford a better opportunity of deſtroying the weeds; and I have heard that on the tolerable rich land, apt to produce weeds, it has done very well in this way; but as I never experienced it, I ſhall not enlarge on that head.

"It is beſt not to feed it the firſt year; but whether it is ſown by itſelf, or with any other crop, it may be mowed the firſt year.

"It is much beſt, if a good crop is deſired, and it is to continue any time to the land, to ſow it in autumn by itſelf, the earlier the better; the proper ſeaſon is from the beginning of Auguſt to the end of September; but if you mix it with other grain, let it be ſown from the beginning of February to the end of March; the earlier in either ſeaſon, the better.

"I have, I think, before obſerved that the land cannot be made too fine for this plant; and it ſhould be well harrowed before ſowing, and again harrowed afterwards to cover the ſeed.

"I muſt once more repeat, that it muſt not be fed the firſt year; for the ſweetneſs of the graſs will cauſe the cattle to bite it too near the ground, which will greatly injure your crop: in fact, it is our practice not to let great cattle feed it till the third year, particularly in grounds that are inclinable to moiſture; for the roots are tender, and much treading is very injurious to it.

"When the ground is well covered, ſuppoſe in the third year after ſowing, if you intend to mow your ſaintfoin, it is beſt to lay it up by the middle of April at fartheſt; but it is better done three or four weeks ſooner. The time for cutting it is when it begins to flower, as it is then fulleſt of ſap: this will ſometimes be about the middle of May, but often later, according as the ſpring is cold or warm.

"In feeding it ſome neceſſary rules are to be obſerved. In the ſpring turn in your great cattle, and you may be pretty certain the buds will not be cropped too near. Oxen thrive well on it, without the danger, at their firſt grazing, that is to be apprehended from clover, &c. yet even this danger chiefly ariſes from the negligence or ignorance of the hinds.

"In the autumn, and part of the winter, you may feed your ſheep on it, which, if in health, will thereby be very ſuddenly fattened.

"Saintfoin hay is excellent food for horſes, and they are uncommonly fond of it.

"If you turn your cows in ſpring in your ſaintfoin lay, you will find it will breed in them abundance of milk; and all my acquaintance know that the butter made of it is excellent.

"When it is intended to ſave the ſeed of ſaintfoin, it is beſt to roll it in the ſpring, that the ſtones may be preſſed down, and the ſcythe go cloſe to the ground; or elſe the beſt ſeeds, which grow on the lowermoſt joints, will be loſt.

"When land is inclined to moiſture, ſaintfoin may thrive very well on it till a wet winter comes; but it is then a great chance if it is not deſtroyed.

"In this county it has long been the opinion of the ableſt farmers, that it is beſt not to dung our ſaintfoin: for the dung ſerves only to encourage weeds, and ſeldom reaches deep enough to give any ſupply of nouriſhment to the roots of the ſaintfoin.

"I have, if I miſtake not, before obſerved that the treading of great cattle, particularly in winter, is hurtful to this graſs: I would therefore by no means adviſe the farmer to fodder his cattle on it, as the field will thereby be poached full of holes, in which the wet lodging, it is a chance but the roots of the ſaintfoin are rotted by it.

"I have often fed my ſheep in winter with ſaintfoin hay; but whenever I intended this, I always cut my ſaintfoin ſome little time before it flowered: it is very eaſy to obſerve when the flower cup is forming: the ſheep will eat it very clean, and thrive well on it, provided it is not old and ſticky.

"When I ſay that ſheep in autumn will ſatten very ſuddenly on ſaintfoin graſs, it muſt be obſerved, that I did not mean the aftermath of ſuch as had been mowed that ſeaſon; but the ſecond growth, when the field had been for ſome time ſhut up after the great cattle had fed it in

the ſpring. The aftermath is, it is true, good for ſheep; but, I think, not quite ſo good as the aftermath of natural graſs; at leaſt, this I am certain of, that turn ſome ſheep into a field where there is a mixture of natural graſs and ſaintfoin, both of which have been mowed, they will to chuſe eat up the firſt, before they touch the other with any degree of appetite.

"Saintfoin ſhoots very early in the ſpring, and to nip in the bud is very injurious; I would therefore adviſe that the ſheep be taken out about Chriſtmas, ſoon after which time it often begins to grow.

"Some of our Wiltſhire farmers have had a cuſtom of ſowing their ſaintfoin ſeed under furrow; but I do not much approve of this practice, though they ſay in light land it cannot be buried." *Muſeum Ruſticum, vol.* I. *pag.* 463.

The following method of cultivating ſaintfoin in Switzerland was written by an experienced huſbandman of that country.

"You have bought, you ſay, a little eſtate, at no great diſtance from the metropolis, and have thought of improving ſome of the lands by ſowing ſaintfoin: you requeſt me to let you know what are the methods in practice in this country relative to that graſs, as, when you left Switzerland to go to our uncle in London, you were too young to gain the neceſſary knowledge in farming. I ſhall oblige you with pleaſure, and the rather as I have had very good ſucceſs myſelf in this particular article.

"The roots of ſaintfoin, ſays he, penetrate very deep into the earth, by which means they do not exhauſt the ſurface ſo much as one would imagine, the vigour of the plant conſidered: the roots are perennial, and conſiſt of a white woody ſubſtance within, covered by a black outward coat or bark: from the crown of the root proceed ſeveral leaves, and ſome branches about two feet long, which incline on all ſides. Our fodder is furniſhed from theſe branches and leaves. Saintfoin is a very vigorous plant, and yields a moſt excellent fodder.

"It is not nice with reſpect to ſoil, but grows in almoſt any, if we except ſuch as are clayey, very damp, and low, or ſtoney: the crop is in proportion to the goodneſs of the land; but the ſaintfoin that grows on poor land, though leſs in quantity, is moſt nouriſhing and heartening for cattle: the virtues of it ſeem concentrated, and the cattle thrive much better on it than on ſuch as grows in greater quantities on rich mellow land.

"When we have it in our power to chuſe our ſituation and ſoil for ſaintfoin, we ought to prefer a light land, gently ſloping on the ſouth ſide of an eminence: here it proſpers to admiration.

"This plant does not thrive in the ſhade; for this reaſon we ſhould avoid having any trees in the fields that bear ſaintfoin: and it is ſubject to be ſometimes chilled, by having ſnow lie too long on it in winter; it ſhould not therefore be ſown on flat level land.

"To have a good crop, the land ſhould be properly prepared, by having two or three good plowings between harveſt and barley ſeed-time: the ſtones muſt be very carefully picked off the field; and it muſt be cleaned from all kinds of weeds, and other ſuch traſh.

"If it is likely that there will be a wet ſeaſon, the ſpring is the beſt time for ſowing ſaintfoin, as it will be much forwarder than that ſown in autumn: but if the ſpring is too dry, the ſowing will beſt be deferred till about Auguſt, as by that means the plants will have time to acquire ſtrength in their roots, and make vigorous ſhoots in the ſpring.

"The farmer may take it for granted, that if the ſoil will admit of it, he cannot well plow his land too deep, or make it too fine: he will reap all the benefit of it in his ſucceeding crops.

"In Switzerland we ſow it three times as thick as we do wheat; or, which amounts to the ſame thing, we uſe the ſame weight of ſeed, the ſaintfoin ſeed being ſo much ſmaller as to make that difference.

"Good ſeed ſhould be heavy, plump, bright, and of a yellowiſh red colour: if, on opening the pods, you find the ſeeds black and ſhrivelled, reject it as of no value; for it has been heated in the heap and will not grow: if it appears white and ſhrivelled, the plant was cut before the ſeed was ripe; from this you are to expect only ſtarved, meagre, ſhort-lived plants: you muſt therefore by no means ſow it. The pods incloſing good ſeed ſhould be plump, large, and armed on one ſide with ſmall prickles: and they ſhould alſo be of a deep brown colour: but it is beſt not to depend on the appearance of the pods, but open them, and examine the ſeed.

"The weather ſhould be mild at the time of ſowing the ſeed of ſaintfoin; and it ſhould be harrowed in, and not covered with above two inches of the earth at moſt: ſome ſow it in the ſpring with oats; but this I by no means approve of: it is much better ſown alone, eſpecially if you would have a ſtrong vigorous plant, that ſhall laſt for years.

"In our very poor lands in Switzerland we ſometimes purſue the following method.

"Immediately after harveſt we give the land intended for ſaintfoin a good deep plowing, laying it in high ridges; in this manner it is left to be mellowed by the froſt and ſnow; we take advantage of the firſt hard froſt to carry on our dung, and manure it well.

"When the froſt breaks in the ſpring, we ſpread the dung, and turn it in with the plow: we afterwards beſtow at leaſt two more plowings on the land, not only to keep down the weeds, but to make the land as fine as poſſible: in autumn we ſow wheat, and have reaſon to expect a tolerable good crop.

"When the wheat is got in, the land is again plowed, and left to meliorate and pulverize by the winter froſts: early in the ſpring it is plowed and laid level, the ſtones are all picked off, and the weeds cleared away: if rain is expected, it is now ſown pretty thick with the ſaintfoin, otherwiſe the ſowing is deferred till autumn. When poor land is managed in this manner, it will yield tolerable good crops of ſaintfoin for ſeveral years: it ſhould not, however, be fed the firſt year, as the treading of the cattle will deſtroy the crown of the plant, and prevent its ſhooting the ſucceeding year: and ſheep ſhould never be turned in to feed on it, as they will crop it ſo cloſe as to prevent its budding.

"Saintfoin comes up about a fortnight after ſowing it, and if the weather is moiſt, ſomething ſooner. When the plants are come up, they ſhould be ſet out at a proper diſtance with a hoe, that they may have room to ſpread. The young plants are very apt to be choaked by weeds; they muſt on that account be kept very clear of weeds, till, by their branches, ſtalks, and leaves, they cover the land; after which there will be no danger of the weeds getting a-head.

"As ſaintfoin ſeed is often faulty, it will not be amiſs to

to make a trial of it, by ſowing ſome of it in a detached bed of a garden, counting the ſeeds before they are put into the ground: by this means it may eaſily be known how many of them fail, and the quantity of ſeed to be ſown may be proportioned accordingly.

" Some have aſſerted, that ſaintfoin ſhould not be mowed the firſt year: but this is an ideal precaution; for in Switzerland we think it rather does it good than harm to mow it in autumn; and experience every day convinces us we are right in our opinion. The firſt crop is not, it is true, very large; but the mowing cauſes the plants to branch, and gives ſtrength to the roots.

" No cattle, as I ſaid before, ſhould be turned on ſaintfoin the firſt year: and indeed, it is beſt, if poſſible, always to mow it. We have three crops of green fodder or two of hay, from it, in one ſeaſon in this country.

" When we intend to ſave the ſaintfoin ſeed, we leave a part of it ſtanding, and do not cut it till we obſerve, by the colour of the pods, which will then be of a deep brown, that the principal part of the ſeed is ripe: we then either gather the heads by hand, or reap them with a ſickle, and lay them carefully on a cloth. The heads muſt be dried in layers three or four inches thick: if they were laid thicker, they would be apt to heat and ſpoil: when dry, we gently threſh them with ſticks; flails would be too heavy; for if the ſeed is the leaſt bruiſed, it does not come up. The ſtubble that remains after the heads are cut off may be mowed, and given either dry or green to the cattle; for though a little ſticky, they will not refuſe to eat it.

" I generally uſe my ſaintfoin green, foddering the cattle with it as ſoon as it is cut; and this I the rather do, becauſe the making it into hay is ſuch critical work: but when there is a likelihood of my being ſhort of winter-fodder, I have no choice to make.

" The weather ſhould be very fine when it is cut; for as it is full of ſap, it requires great heat to dry it; and if it happens to rain, it takes more damage than common graſs; and it is beſt not to cock it, as it is ſubject to heat in a very ſmall ſpace of time: if it is much wetted, it grows black, and loſes all its ſweetneſs

" Even when ſaintfoin is ſeemingly quite dry, it is apt to heat in the ſtack; but this is eaſily prevented by ſpreading alternately a layer of good oat or barley ſtraw, and another of ſaintfoin; when it comes to be uſed all together, it makes an excellent winter-fodder.

" Great care muſt be taken both in turning the ſwarths of ſaintfoin, and in loading it on the waggons, as a very little ſtirring will, when it is dry, ſhake off all the leaves; and this greatly leſſens its value: for this reaſon I make my men turn the ſwarths with the handles of their forks, which is eaſily done; and I never cart it, but either early in a morning, or late in the evening, when it is ſomewhat moiſtened by the dews.

" Saintfoin is a very hardy plant, and bears, without being ſenſibly affected, the extremes of heat and cold; but the bottom of the land where it is ſown muſt not be wet, and there muſt be room for the roots to ſpread.

" A field of ſaintfoin on a good ſoil will laſt from ſixteen to twenty years in prime, and even longer, with care; for if, after ſeven or eight years, ſome well-rotted dung is laid on it, the future crops, as well as its duration, will be greatly increaſed. When it is ſown on light land, marling it is of very great ſervice.

" But if after all a piece of ſaintfoin falls off, our method is to plow it up in autumn as deep as poſſible; give it another plowing in ſpring, ſow it with oats, plow it again immediately after harveſt, dung it, ſow it with wheat; and when the wheat is off, plow it again, and giving it another plowing ſow ſaintfoin in it about the end of Auguſt; and this in general ſucceeds as well as that which was firſt ſown on the land.

" Before I conclude, I muſt give you a few cautions relative to this excellent fodder, which has of late ſo much improved this neighbourhood.

" It is ſo very ſweet, and cattle are ſo fond of it, that without great care they are apt to eat too much of it; whence often proceeds a ſurfeit, and ſometimes a corruption of the maſs of blood, and cutaneous eruptions: they ſhould at firſt have but a little at a time given them, that they may be by degrees habituated to it: by this management the danger vaniſhes.

" It is much more proper for ſlow draught-horſes than for ſuch as are uſed for berlins, or for riding; for it is apt to make horſes thick-winded, foggy, and ſomewhat ſluggiſh: for farmers horſes nothing can be better, or more nouriſhing; ſpeed is not required in them.

" When ſaintfoin is intended to be made into hay for horſes, it is beſt not to cut it till the ſeed is formed in the pod, as by that means the hay will be much more nouriſhing; and when the dried ſeed itſelf is plenty, nothing better can be given to the horſes by way of corn; for I can aſſure you from experience, that one buſhel of it will go as far as two of oats.

" When ſaintfoin is cut to be given green to cattle, it is beſt to mow it when it is in full bloom, as it is then moſt juicy, and fulleſt of ſap, and it will conſequently afford moſt nouriſhment to the cattle. The beſt way of managing is to cut no more than will ſerve for the day; and by properly apportioning, or parcelling out the field, there will be, during the whole ſummer, ſome of it in order to cut for green fodder.

" If this green fodder is intended for ſheep, it may with great propriety be cut juſt before it flowers: the ſtalks are then in a tender ſtate, and very nouriſhing and good either for wethers or ewes. When it is to be made into hay for ſheep, the ſame rule ſhould be obſerved.

" I have very little more to ſay on the ſubject of ſaintfoin, except that, as when a ſaintfoin lay is brought into tillage, it prepares land very well for wheat or rye, and bears good crops, there is ſeldom occaſion among the good farmers to try how long it will continue in heart, as they generally break up theſe lays in turn, and find it advantageous ſo to do. *Muſeum Ruſticum, vol.* I. *page* 37.

Experiments on Saintfoin.

The following judicious ſeries of experiments were communicated by a gentleman of diſtinguiſhed rank and fortune, in Yorkſhire.

" From an entire conviction, ſays this excellent huſbandman, that it is the duty of every ſubject to contribute all in his power to the good of ſociety, I have endeavoured, during ſeveral years that I have reſided in the country, to promote and encourage the advancement of agriculture. To this end I have made variety of experiments, on different ſoils, to prove and aſcertain the moſt beneficial methods of huſbandry, or how to employ land to the moſt advantage.

"A great part of my eſtate, conſiſting of waſte and uncultivated heath, which did not let for more than a ſhilling an acre, I judged it to be a matter of importance to try if it was not poſſible, by culture, or by applying this ground to a different purpoſe, to increaſe the value of it. Happy would it be, could pleaſure be made to coincide with profit! and it is certain, that whoever ſucceeds in the improvement of his own eſtate, may enjoy the inward ſatisfaction of rendering ſome ſervice to his country: for the example of a landlord may be thought to have ſome weight with his tenants; and if, amidſt a great number of experiments made for the ſake of truth, ſome have proved ſucceſsful, one may expect that the farmer will at laſt adopt a method which he has for many years ſeen repeated with advantage: for however the common farmer may have been accuſed of an obſtinate adherence to old cuſtoms, many inſtances might be produced of his quitting the paths of his anceſtors in favour of modern improvements; but then he muſt be thoroughly ſatisfied, that the new way is indeed preferable to the old, not in theory only, but in practice, confirmed by actual experiments often repeated before his eyes. And can we juſtly blame the illiterate peaſant for refuſing to forſake a method he is well acquainted with, and can depend on for the ſupport of himſelf and family, upon other terms? It is the province of the landlord to adopt a theory, and to try it by experiment; for if it fails, as is often the caſe, his ruin is by no means the conſequence, and the loſs is amply made up to him, by the ſecret pleaſure always accompanying a good intention. But whatever ſervice a gentleman may be of in encouraging reſearches of this nature, or by his influence in his own neighbourhood; yet ought his benevolence to extend farther, ſo as to be of uſe, if poſſible, to his country and mankind. It is the deſire of communicating the little knowledge I may have gained from the experience of a few years, that has prompted me to addreſs this letter to you, who are engaged in an uſeful and public undertaking: and you are at full liberty to make uſe of it, together with the detail of the experiments. They were begun without the leaſt deſign of making them public, and may therefore be deficient in point of method and order: but they are ſtrictly true.

"On the third of April, 1759, two acres of very ſandy land (which had a hundred loads of red marle laid on it the year before, and had borne a good crop of oats in 1758) were drilled with ſaintfoin, on four feet ridges in double rows, eleven inch partitions, the intervals three feet one inch wide, and took four pecks and a half of ſeed. This was intended to be horſe-hoed, as Tull directs; but the land was in ſuch bad tilth, and abounded ſo with the natural graſs, that, after once or twice attempting to deſtroy it, by plowing the intervals, the horſe-hoeing ſcheme was given up, and the ſaintfoin left to take its chance. However, a few plants remained thinly ſcattered in the rows (whether this thinneſs was owing to the badneſs of the ſeed, or to its being ſown too deep, I know not, though I rather impute it to the latter cauſe, as, in ſandy land, the ſhares of the drill are very apt to penetrate too far into the ground.) Theſe remaining plants flouriſhed exceedingly from the time of their being ſown; many were in flower the following June, and afforded a tolerable crop, viz. about a load. The after-eatage was very good. In 1760, theſe plants ſeemed to have arrived at their perfection, and the product was two waggon loads, or about two tons. In 1761, and 1762, this ſmall cloſe, having had ſome manure laid on it yearly, yielded nearly the ſame quantity of hay; and it is now let for forty ſhillings a year: a much higher rent than any land is let for in this neighbourhood, and four times the rent paid for it before the improvement.

"N. B. This cloſe of two acres was ſeparated from another of twenty-ſeven acres, of ſo ſandy and dry a nature, that, unleſs in a wet ſummer, the hay upon it was ſcarce ever worth mowing: and this experiment was made in order to determine what improvement the adjoining large cloſe was capable of, and to experience whether or no the common opinion, that ſaintfoin is improper for all ſandy and deep ſoils, be founded on truth, or only the reſult of prejudice: for the reaſon given for its diſagreeing with this kind of ſoil, did not appear to me ſatisfactory; and great part of my eſtate conſiſting of ſuch ſandy land, it ſeemed a matter of importance, to know, whether the great advantage derived from ſaintfoin, on ſome ſoils, might not alſo be applicable to ſandy ſoils.

"Encouraged by the flouriſhing condition of the ſaintfoin on this ſmall cloſe, I determined to extend the improvement to the larger one alſo, as ſoon as it could be brought into ſufficiently fine order to be laid down with this graſs. Accordingly, in the winter of 1759, twenty-five acres were plowed with the five coultered plough, as recommended by M. Duhamel, in his Treatiſe on the Cultivation of Land, in order thereby to prepare the ground for turnips the enſuing ſummer; for I look upon this as one of the beſt methods of deſtroying the natural graſs, and preparing the land for any of the artificial graſſes; eſpecially if the turnips are drilled in rows, and cultivated with the horſe-hoe. The land was plowed level in the ſpring of 1760, and into ridges of about five feet broad in June, and a ſingle row of turnips was drilled on the middle of each ridge in July. It is to be obſerved, that the natural graſs was far from being deſtroyed by theſe three plowings; nor could it be entirely ſo by the ſubſequent hoeings of the turnips; ſo that it certainly was a great prejudice to the ſaintfoin. The ſame ground is now ſown again with the ſame plant: but I would ſtrongly recommend to thoſe who are inclined to follow this method on ſuch a ſoil as I have deſcribed, to continue the culture of turnips, with the horſe-hoe, two years, inſtead of one: for by this means, the natural graſs and weeds may probably be effectually deſtroyed. But to return to the experiment: the turnips ſucceeded as well as could be expected on ſuch a ſoil, and without manure: they were eaten off by ſheep, and Scotch cattle, folded on the land.

"About four acres, on which the turnips were the firſt ſpent, were plowed level, and afterwards, viz. in November, drilled with ſaintfoin in equally diſtant rows, one foot aſunder. They took about a buſhel to an acre. This was an uncommon, and may be thought an improper ſeaſon for the ſowing of ſaintfoin: but I choſe to ſow part of the field before winter, and part in the ſpring, part with ſaintfoin mixed with corn, and part with ſaintfoin alone; in order to ſee which method would ſucceed beſt, that I might make it my guide in other places, more likely to yield good crops.

"Five or ſix acres of land were drilled in the beginning of April 1761, with ſaintfoin ſeed, in rows, at the ſame diſtance, and with the ſame proportion of ſeed, as the four acres ſpoken of before: about three acres were

ſowed

ſowed ſoon after with ſaintfoin and oats, both drilled: and about twelve acres were drilled with ſaintfoin and barley; each in rows, about a foot aſunder. The whole of this field, which contained twenty-five acres, had been plowed but once ſince the turnips; whereas two plowings might have been better: but, on account of eating them off with ſheep and cattle, there was not time for it.

"The three acres ſowed with oats in rows a foot aſunder, took four buſhels and a half of ſeed, and produced a very good crop; by computation, five quarters to an acre: but the exact quantity, neither of the oats, nor of the barley, could be known, on account of its being mixed in the barn with corn that grew in other places. The twelve acres ſowed with barley took ſeventeen buſhels of ſeed, and produced a much greater crop than any land in the neighbourhood; though this was a great year for barley. All the farmers who obſerved this crop, allowed that they had never ſeen finer barley; and it may be ſaid, without the leaſt exaggeration, to have yielded above five quarters to an acre. I am convinced that this computation of five quarters to an acre is a very moderate one; not only from the number of ſheaves, and the judgment of all who ſaw it; but likewiſe becauſe I had no more than twenty-ſix acres and an half of land drilled with barley this year; and the whole produce, when threſhed, amounted to one hundred and twenty-eight quarters and two buſhels; which is very near five quarters to an acre, taking one part with another: but theſe twelve acres bore by much the greateſt crop in proportion, and ſeven acres of the twenty-ſix were ſown on beds five feet broad, and horſe-hoed, which never produces ſo large a crop.

"The ſummer of 1762 was remarkably dry, and bad for graſs: many fields hereabouts, of ten acres, did not produce above a load or two of hay; but this of twenty-five acres produced twelve tons of good hay: which, conſidering that the ſaintfoin was not nearly arrived at its perfection, may be ſaid to be conſiderable.

"It was now eaſy to ſee in what parts of the field the ſaintfoin had ſucceeded beſt.

"The four acres ſowed before winter had the ſmalleſt number of plants of ſaintfoin of any; perhaps not more than one or two in ten yards: but this ground abounded ſo with natural graſs, that this alone furniſhed a tolerable crop. The five acres ſown in the ſpring, without corn, did not abound much leſs with natural graſs, or more with ſaintfoin, than the preceding: but there being a great mixture of the ſeeds of rye-graſs with all the ſaintfoin ſowed in the field, the rye-graſs appeared diſtinctly in tufts all along the rows; and, together with the natural graſs, ſeemed compleatly to have covered the ſurface of the ground. The rows were much better ſtocked with ſaintfoin plants in the twelve acres ſown with it and barley: but the rye-graſs abounded here likewiſe.

"It is remarkable, that the ſaintfoin flouriſhes beſt in thoſe parts of the field where the land is moſt barren; the reaſon of which undoubtedly is, that, as ſcarce any natural graſs, or weeds, ariſe to choak it there, its young and tender ſhoots have the benefit of the whole paſture, and its roots are not obſtructed in their progreſs by the growth of other plants.

"Though the greateſt part of this field is much underſtocked with ſaintfoin plants, yet it is in a very promiſing condition for a good crop of hay this year.

"I attribute the bad ſucceſs of the ſaintfoin on the firſt four acres, partly to its being ſowed too late, whereby the plants could not acquire much ſtrength before winter, which deſtroyed many of them; partly to ſome violent hurricanes of wind, which blew crouds of ſand from one part of the field to another, and overwhelmed many plants; and partly to the ſhares going too deep, by which the ſeed was covered at leaſt two inches. The bad condition of the five acres ſowed alone in the ſpring, I believe to be owing, in ſome meaſure, to the cauſes already aſſigned, and alſo to the want of protection and ſhelter from drought, which corn would have afforded in that very dry ſoil. Barley does alſo help to ſtifle the natural graſs, ſaintfoin's greateſt enemy. The ſaintfoin which was drilled with barley, looked, as was before obſerved, by much the beſt: but, indeed, ſome precautions were uſed to ſow the ſeed ſomewhat ſhallower on theſe twelve acres; and this may, in ſome degree, have contributed to its ſucceſs.

"Upon the whole, from the experiments made in this field (and ſeveral others made ſince have ſtrengthened my opinion on that head) I conclude, firſt, that ſaintfoin is very ſuitable to any ſandy or deep ſoils, provided they are dry, and that the natural graſs and weeds can by any means be compleately deſtroyed: ſecondly, that it is better to ſow ſaintfoin in the ſpring, and with barley, than in the autumn, or ſpring, alone: thirdly, that the ſeed ſhould not be covered above an inch deep; but I believe half an inch the moſt proper depth. One foot may be a very proper diſtance for drilling the rows; and from a buſhel to a buſhel and an half, a proper allowance of ſeed for an acre of ground, provided that ſeed be good.

"I have tried the horſe-hoeing of ſaintfoin ſown on beds three and four feet broad; but, though the plants do by that means certainly grow more vigorous, I do not think the crop ſo great; and when the ſtalks are ſtrong and pipy, I have obſerved that cattle will not eat them. The ſowing in equally diſtant rows ſeems preferable, eſpecially where a large extent of ground is to be ſowed. But my experience is very inſufficient to decide this point abſolutely. I could wiſh that gentlemen would make trials of the horſe-hoeing of ſaintfoin in different ſoils and ſituations.

"Experiments carefully made, and often varied, by perſons void of prejudice, may, in time, decide that important queſtion in agriculture, viz. whether the common, or the horſe-hoeing, huſbandry be, upon the whole, moſt advantageous to the Engliſh farmer.

"If ſaintfoin be drilled on a ſandy ſoil, or on one that is in very fine order, the ſhares of the drill ought to be two inches thick, or they will go too deep; and a ſmall wooden roller ſhould be fixed to, and follow, the drill, inſtead of a harrow with teeth, which would bring too much earth upon the ſeed. Such a roller will lay the ground ſmooth, and fitter for mowing. A ſpring made of three pieces of aſh, as deſcribed by M. Chateauvieux, is of great uſe, and may eaſily be added to Mr. Tull's drill plough. It may be faſtened underneath the middle of the plank, by four ſcrews, and made to preſs more or leſs on the roller, or harrow, which ever is made uſe of, by a wedge put in betwixt the ſpring and the hinder edge of the plank. If a harrow is uſed, iron teeth are much preferable to wooden ones.

"In the year 1757, I had a mind to try how much a ſoil naturally extremely bad, could be improved by art. Accordingly, I made choice of a piece of ground one acre and an half in extent, a barren ſand, which produced only a few miſerable weeds, and which the farmer who rented it did not think worth his while to cultivate. There happened

pened to be a great quantity of red ſtony marle in an adjoining field, of which near three hundred loads were laid on this acre and an half. It was drilled with barley in 1758, and horſe-hoed: but the crop proved a very bad one. In 1759, a load of lime, and about ten loads of dung were laid thereon, and it was drilled with turnips and horſe-hoed: however, the crop ſtill was but moderate; though a good deal better than could have been expected from ſuch a ſoil. In 1760, it had turnips again, managed in the ſame manner as the former, but they were a great deal better. In 1761, it was drilled with oats, ſaintfoin and rye-graſs, mixed, in equally diſtant rows one foot aſunder. It took two buſhels and a peck of oats, and two buſhels of graſs ſeeds. The oats were very good, and produced four quarters and four buſhels. By continued horſe-hoeing three years together, the land was got into perfectly fine order, the marle and ſand were thoroughly incorporated, and the natural graſs and weeds intirely deſtroyed: ſo that the ſaintfoin and rye-graſs grew and flouriſhed exceedingly. In 1762, the ſummer being uncommonly dry, the produce was about half a load of hay; which was as much as one could expect the firſt year after ſowing. It is very well ſtocked with plants, which now, in May 1763, ſeem as vigorous as in any of my other fields, though I have ſome which yield two tons of hay to an acre. This little piece of ground, which before was not worth a ſhilling a year, is, by the labour and coſt beſtowed on it, now worth at leaſt fifteen ſhillings an acre; which is a proof that, let land be ever ſo bad, it may be improved, and perhaps made equal to the beſt in the neighbourhood: but at the ſame time it muſt be confeſſed, that the expence is too great to be repeated at once on a large extent of ground. I calculate that three hundred loads of marle, dug and carried about three hundred yards, might coſt about four-pence a load, or five pounds for three hundred loads, which has been the whole expence attending this acre and half: for the manure, plowings, and horſe-hoeings, were repaid by the crops of barley, oats, and turnips."

Mr. Duhamel has mentioned the following experiments relative to the culture of ſaintfoin:

In 1754, M. Eyma, near Bourdeaux, planted ſaintfoin, lucern, and clover, in rows eight feet aſunder, with diſtances of ſixteen inches between the plants in the rows, which yielded him an immenſe increaſe. The alleys were horſe-hoed after each cutting.

In 1755, he planted a field, a little more than three roods ſquare, with ſaintfoin, which he cultivated according to the rules of the New Huſbandry: and this ſpot yielded him 10,000 pounds of dry hay. M. de Chateauvieux had 15,300 pounds of lucern, as we ſhall ſee, off ſomewhat more than an acre of ground, which he cut five times; but M. Eyma thinks that 14445 pounds, Geneva weight, of ſaintfoin, which he had at another time, at one cutting, is a greater crop than M. de Chateauvieux's lucern; beſides the after crop, which indeed was but inconſiderable, on account of the dryneſs of the ſeaſon. He ſays he cuts his ſaintfoin three times in good years, and that the two laſt cuttings produce nearly as much as the firſt: but he allows, that ſuch years are not to be expected often.

M. Eyma doubts whether the preference be due to ſaintfoin or to lucern: but he is confident that either of them, properly cultivated, will produce ſurprizing crops.

He thinks that one row of ſaintfoin, or lucern, planted in the middle of a bed three feet wide, will profit more by the different hoeings, and conſequently produce more graſs, than double or triple rows, though theſe laſt be planted on broader beds; becauſe the ſingle rows have the earth looſened on each ſide of them.

M. Diancourt ſowed ſaintfoin, each plant of which, in 1753, had a head of two feet diameter. They throve ſo well, that, in 1755, one plant, and that not the largeſt in the field, yielded twenty-three ounces of hay.

The following inſtructions were given by an ingenious gentleman in Lincolnſhire.

"Mr. Tull ſays, that a deep ſoil is beſt for faintfoin. I believe every thing grows better, in a better ſoil: but by what I have ſeen of this plant, I ſhall always prefer for it a ſhallow ſoil, where there is a rock, or ſome hard ſubſtance, within ſix inches, or a foot, of the ſurface, to ſtop the roots of the plants, and make them ſpread horizontally. This has not only the good effects propoſed in M. de Chateauvieux's manner of tranſplanting lucern, but, it is ſaid, occaſions its filling the ground with more ſhoots by their ſtriking up from the knots of the roots. This fact I cannot verify: but certain it is, that, in ſuch ſoils as I here ſpeak of, a crop of ſaintfoin which at firſt appears very thin, will afterwards fill the ground perfectly well, and the plants of it will appear in much greater quantities than at firſt.

"I have ſeveral times broke off a root of ſaintfoin four or five inches within ground, and it always ſprang up again. This is a ſmall argument for the fact I mentioned.

"Saintfoin is much cultivated in Lincolnſhire. The common allowance of ſeed is five buſhels to an acre. A gentleman ſouth of Lincoln adviſed me always to ſow a ſmall quantity of trefoil with it (about four pounds on an acre). The reaſon is, that, in this expoſed country, the young plants ſuffered more by the ſun in ſummer, than by the froſts in winter. Now the trefoil, coming to perfection the firſt year, and living only three, will be a ſhelter for the young plants, during the firſt year or two, and die off when the ſaintfoin wants its room. This ſyſtem is well ſupported by practice: but rye graſs ſhould on no account be ſowed with it; that being, when left for fodder, a great impoveriſher of ground.

"Saintfoin is obſerved to get to perfection in three years, laſts good four or five, and then dwindles during four or five more. Its firſt crops are from one or two loads; its ſecond ſtage, from three to four loads, and it dwindles down again to one.—Laſt ſummer, which was remarkably dry, did very well with this graſs.

"I have ſown ſaintfoin with barley, with wheat, without corn in the ſpring, and now" (this gentleman's letter is dated September 4th, 1763) "am ſowing ſome more at this preſent writing; but can form no judgment as yet.

"Three years ago I drilled ſome, according to Mr. Tull's directions, in beds, with treble rows, and ſome at equi-diſtant rows. The horſe-hoed beds were good, as far as they went: the others, drilled at a foot diſtance, gave ſo much room for weeds to come up, that the ſucceſs was very moderate; which, indeed, would have been the caſe with the former, had not the horſe-hoe cleared them. On the whole as far as my ſmall experience and obſervations reach, I would never chuſe any one to drill his ſeed, but to ſow it in the broad caſt-way, on land very fine, with a good quantity of ſeed."

SALLENDERS, a diſeaſe in horſes, conſiſting in cracks in the bending of the hough, and occaſion a lame-

neſs

neſs behind. This diſeaſe is cured in the ſame manner as the mallenders. *See* MALLENDERS.

SALT-MARSHES, paſture-lands lying near the ſea, and ſometimes overflowed by the ſea-water.

"It has been obſerved, ſays an ingenious writer in the Muſeum Ruſticum, that horſes and black cattle thrive better, and get fleſh and fat ſooner, in ſalt marſhes, than in freſh-water meadows or upland paſture; yet I do not remember ever to have heard any good reaſon aſſigned for it.

"Some will tell you that the air of the ſea whets their appetites; that the paſture is rich and nouriſhing; and that the herbs produced by the lands near the ſea are more conducive to the health of herbaceous animals, than ſuch as grow on upland paſtures, whether natural or artificial.

"But may we not rather attribute the thriving of cattle on theſe marſhes, to the ſaline particles with which the earth as well as its produce, is, when near the ſea, ſtrongly impregnated? Perhaps even the dews have their portion of ſalt; but of this I have made no experiment, therefore mention it only as a probable conjecture; for as they fall ſoon after they are exhaled from the ſea, without paſſing through the ſecretions neceſſary to ſeparate their ſaline parts, why ſhould not this be the caſe?

"But to return to my firſt ſubject: I am fully of opinion, that the ſaline particles only, with which the graſs is impregnated in the above-mentioned marſhes, cauſe cattle to thrive in them in the manner they are known to do. Theſe ſalts purge away the foul humours which the beaſts have contracted, either by idleneſs, or by being overheated in labour; by which means they are better diſpoſed to be nouriſhed by the aliment they receive.

"It may, perhaps, be objected, that if the graſs of theſe marſhes is apt to purge cattle, this very purging, by being long continued, will be a means of preventing their growing fat. To this I anſwer, that the cattle take with their food every day nearly the ſame quantity of theſe purgative particles; but that the quantity of ſalt, which at their being firſt put into the marſh will have that effect, will ceaſe producing it when they are, by cuſtom, habituated to take a daily portion of it: this muſt be allowed, as we all know, that a few grains of rhubarb will operate as a cathartic to a perſon that is not accuſtomed to take it; yet it is as well known, that a man may take many grains daily, if he uſes himſelf to it, without its being ſenſibly purgative to him.

"It is not convenient to every one to ſend their cattle to a ſalt marſh: would it not, therefore, be happy, if we could ſubſtitute a method that would nearly anſwer the ſame purpoſe? I do not think this impoſſible: perhaps, if common ſalt-water was to be laid in the fields for the horſes to lick as often as they pleaſed, they would thrive much better: were I to ſay I know it would have that effect, it would be no preſumption.

"Cattle are naturally fond of ſalt, and if left at their liberty, will take no more of it than what does them good. With this help, our freſh-water meadows, and upland natural and artificial paſtures, would yield us a greater profit, and of courſe be worth more both to the land-owner and farmer.

"Some will not allow a thing to have merit, unleſs it is ſupported by what they call a proper authority; and they do not allow the experiments of a particular perſon to be ſufficient. To ſatisfy ſuch I can aſſure you, that in the inland parts of Switzerland, when their horſes and cattle have endured the hardſhips of a long and ſevere winter, they turn them in the ſpring looſe into the mountains, laying ſalt here and there upon the rocks, for them to reſort to when they pleaſe; and of this they are ſo fond, that when the farmers want to catch their horſes, they take ſome ſalt in their hats, as we do oats in a ſieve, to allure them.

"Experience has long convinced them, that the ſalt thus laid in their way anſwers every good purpoſe: their cattle are more healthy in general than ours are in England; and almoſt to this alone do they attribute it.

"In the province of Munſter and Connaught, in Ireland, they very frequently lay ſalt on ſlates, for the benefit of their horſes when at graſs: this, they find, does the cattle great ſervice; and in this ſhould we imitate them, and not be too proud to learn of them, becauſe in Ireland agriculture is not in ſo flouriſhing a ſtate as in England.

"Some few farmers have (to do them juſtice) practiſed this method in our own country; but contenting themſelves with the profit reſulting from it, they have not propagated the knowledge of the many advantages they are ſenſible may be derived from this practice of giving ſalt to cattle.

"The farriers and horſe-jockeys know well the uſe of ſalt; they mix it often in their medicines, and find, by experience, that nothing proves ſo powerful a ſtomachic to horſes, as a little ſalt thrown into their oats.

"I muſt farther obſerve, that the uſe of ſalt is very proper when cattle are turned into clover, lucerne, or coleſeed to feed: it is well known, that, on theſe occaſions, they are very apt, unleſs great care is taken, to be ſurfeited; the ſalt would prevent this accident, and thereby greatly accelerate the fattening of the cattle, and make it much ſafer to the farmer.

"Salt has alſo been found to be of great ſervice in fattening hogs, by cauſing them to drink more plentifully than otherwiſe they would."

For the uſes of ſalt in rendering hay more grateful to cattle, *ſee the article* BRINING *of* HAY-RICKS.

SAND, a genus of foſſils found in minute concretions, forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate ſhape, and appear regular, though more or leſs complete concretions; not to be diſſolved or diſunited, by water, or formed into a coherent maſs by means of it, but retaining their figure in it; tranſparent, vitrifiable by extreme heat, and not diſſoluble in, nor effervеſcing with acids.

Theſe are ſubject to be variouſly blended and intermixed either with homogene, or heterogene particles, particularly with flakes of talc; and according to theſe, and their different colours, are to be ſubdivided into ſeveral kinds, as red, white, &c.

Dr. Liſter divides the Engliſh ſands into two claſſes; the firſt, ſharp or rag ſand, conſiſting of ſmall tranſparent pebbles, naturally found on the mountains, and not calcinable: theſe he farther divides into fine and coarſe, and ſubdivides each, according to the colours, into white, grey, reddiſh, brown, &c.

The ſecond, ſoft or ſmooth, which he ſubdivides into that with flat particles broken from lime-ſtones, that with ſilver-like particles, and that with gold-like particles.

As to ſand, its uſe is to make the clayey earth fertile, and fit to feed vegetables, &c. for earth alone, we find, is liable to coaleſce, and gather into an hard coherent maſs, as is apparent in clay: and earth thus embodied, and, as it

it were, glued together, is no-ways diſpoſed to nouriſh vegetables: but if with ſuch earth, ſand, &c. i. e. hard cryſtals, which are not diſſolvable in water, and ſtill retain their figure, be intermixed, they will keep the pores of the earth open, and the earth itſelf looſe and incompact, and by that means give room for the juices to aſcend, and for plants to be nouriſhed thereby.

Thus a vegetable, planted either in ſand alone, or in a fat glebe, or earth alone, receives no growth or increment at all, but is either ſtarved or ſuffocated; but mix the two, and the maſs becomes fertile. In effect, by means of ſand, the earth is rendered, in ſome manner, organical; pores and interſtices being hereby maintained, ſomething analogous to veſſels, by which the juices may be conveyed, prepared, digeſted, circulated, and at length excerned, and thrown off into the roots of plants.

Grounds that are ſandy and gravelly, eaſily admit both of heat and moiſture; but then they are liable to theſe inconveniencies, that they let them paſs too ſoon, and ſo contract no ligature, or elſe retain it too long, eſpecially where there is a clay bottom; and by that means it either parches or chills too much, and produces nothing but moſs, and cankerous infirmities; but if the ſand happens to have a ſurface of good mould, and a bottom of gravel, or looſe ſtone, though it do not hold the water, it may produce a forward ſweet graſs; and, though it may be ſubject to burn, yet it quickly recovers with the leaſt rain.

Sea ſand is accounted a very good compoſt for ſtiff ground; for it effects the two things following, viz. it makes way for the tree or ſeed to root in ſtiff ground, and makes a fume to feed it.

Sand indeed is apt to puſh the plants, that grow upon it, early in the ſpring, and make them germinate near a month ſooner than thoſe that grow upon clay, becauſe the ſalts in the ſand are at full liberty to be raiſed, and put into motion, upon the leaſt approach of the warmth of the ſun; but then, as they are haſty, they are ſoon exhaled and loſt.

It is remarkable that ſand, tho' it appear a very hard, denſe, and indiſſoluble body, yet is contained inviſibly in the brine, or ſalt water of our ſalt ſprings; and even on the ſhooting of the ſalt, after evaporation, there ſtill remain the particles of it in the clear pellucid ſalt; and this, though wholly ſoluble in water, yet when a brine, made by ſuch a ſolution, is boiled, depoſits as much of the ſand as the common brine of the pits, or ſea water.

Dr. Plot, who was very curious to know the true hiſtory of this ſingular effect, procured experiments to be made in the following manner: eight folds of fine holland, and as many of much finer cambric, were put together, and, a quantity of the brine of the Staffordſhire ſalt pits being ſtrained through this, there was nothing ſeparated from it but a ſmall quantity of black duſt, which ſeemed to have fallen in by accident, and which was not at all like ſand; yet, on evaporating this brine, it was found to contain no leſs than one fourth part as much ſand as ſalt; the quantity of brine yielding a buſhel of ſalt, yielding alſo a peck of ſand.

Some have ſuppoſed from theſe, and the like obſervations, that the ſand was generated during the time of the boiling the liquor, but the more careful examiners think otherwiſe; it appearing to them, that the particles of this ſand may be ſeen in the brine, by the help of a microſcope, before the boiling, in form of rectangular oblong plates, ſome nearly ſquare; theſe were ſo ſmall, as readily to paſs the ſtrainer with the water; and appearing as numerous in it after, as before the ſtraining, ſhew that they are no more to be kept, by ſuch means, than the ſalt.

The pores of the fineſt ſtrainers, examined by the microſcope, appear twenty times bigger than theſe plates, or particles of the ſand, and therefore it is not to be wondered at, that they let them through. There requires, therefore, no more to the formation of the ſand, than the coaleſcing of ſeveral of theſe particles into one larger granule, and ſo on; and this is very likely to be done by means of the evaporation of a part of the fluid which kept them ſeparate, and of the motion given to them in boiling, which naturally and neceſſarily brought them into the ſpheres of their own mutual attractions, at a time when their attraction with the fluid they ſwam in, was alſo much diminiſhed with its quantity. This attraction ſeems even evidently to increaſe between the particles, as the water becomes evaporated, and, when finally the ſalt is drawn from it, and it is examined, as it drops from the baſkets, in which the ſalt is put to drain, it is ſeen to contain more numerous particles of this ſandy matter than before; and theſe are found to coaleſce into yet larger concretions, by degrees, as the remainder of the fluid evaporates from them on the glaſs.

The particles of this ſtony matter, when once thus united, are no more to be ſeparated by water, nor is the matter any longer ſoluble in that fluid. The common ſpar found in form of ſtalactites and incruſtations on the roofs, walls, and floors of old caverns, ſhews that it was once diſſolved in water, and by that means brought to thoſe places, and made into thoſe forms; and it ſhould ſeem, that this ſand, as it is called, was only this ſort of ſpar, which is contained more or leſs in all water; and which, on the evaporating of that water and ſeparation of the ſalt, which might help in making the water a menſtruum proper for the retaining it, ſhoots out into its own natural concretions; for the figure of theſe thin plates is the true and natural thin parallelopiped or rhomboidal figure of the ſmaller concretions of that matter, and even of thoſe pieces into which it falls on breaking. *Phil. Tranſ.* N° 145.

Common ſand is a very good addition by way of manure to all ſorts of clay lands; it warms them, and makes them more open and looſe. The beſt ſand for the farmers uſe is that which is waſhed by rains from roads, or hills, or that which is taken from the beds of rivers; the common ſand that is dug in pits never anſwer nearly ſo well. Sand mixed with dung is much better than laid on alone: and a very fine manure is made by covering the bottom of ſheep-folds with ſeveral loads of ſand every week, which are to be taken away, and laid on cold ſtiff lands, impregnated as they are with the dung and the urine of the ſheep.

Beſides clay land there is another ſort of ground very improveable by ſand; this is that ſort of black foggy land on which buſhes and ſedge grow naturally, and which they cut into turf, in ſome places. Six hundred load of ſand being laid upon an acre of this land, according to the Cheſhire meaſure, which is near double the ſtatute acre, meliorate it ſo much, that without plowing, it will yield good crops of oats or tares, though before it would have produced ſcarce any thing. If after this crop is taken off, the land be well dunged, and laid down for graſs, it will yield a large crop of ſweet hay.

Once ſanding this land will improve it for a vaſt number of years, that it will yield two crops of hay in the year, if

there

there be weather to make it in. Some land in Cheſhire has been, by this means, rendered of twelve times its former value to the owner. The bogs of Ireland, when drained, have been rendered very fruitful land, by mixing ſand in this manner among the earth, of which they conſiſt. Add to this, that in all theſe boggy lands, the burning them, or firing their own turf upon them, is alſo a great advantage. The common peat, or turf aſhes, mixed with the ſand for theſe purpoſes, add greatly to its virtue.

Sea ſand, which is thrown up in creeks and other places, is by much the richeſt of all ſand for manuring the earth; partly its ſaltneſs, and partly the fat and unctuous filth that is mixed among it, give it this great virtue. In the weſtern parts of England, that lie upon the ſea coaſts, they make very great advantages of it. The fragments of ſea-ſhells alſo, which are always in great abundance in this ſand, add to its virtues; and it is always the more eſteemed by the farmers, the more of theſe fragments there are among it.

The ſea ſand uſed as manure in different parts of the kingdom is of three kinds: that about Plymouth, and on other of the ſouthern coaſts, is of a blue grey colour like aſhes, which is probably owing to the ſhells of muſcles, and other fiſh of that or the like colour, being broken and mixed among it in great quantity. Weſtward, near the land's end, the ſea ſand is very white, and about the iſles of Scilly it is very gliſtering, with ſmall particles of talc; on the coaſts of the north ſea the ſand is yellowiſh, brown, or reddiſh, and contains ſo great a quantity of fragments of cockle ſhells, that it ſeems to be chiefly compoſed of them. That ſea ſand is accounted beſt, which is of a reddiſh colour: the next in value to this is the bluiſh, and the white is the worſt of all.

Sea ſand is beſt when taken up from under the water, or from ſand banks, which are covered by every tide.

The ſmall-grained ſand is moſt ſudden in its operation, and is therefore beſt for the tenant who is only to take three or four crops; but the coarſe or large-grained ſand is much better for the landlord, as the good it does laſts many years.

Where the ſand is dredged out of the ſea, it is uſually twice as dear as where it is taken from the ſand banks.

When the land has been well manured with the large ſand, they take four crops of corn from it, and then lay it down for paſture for ſix or ſeven years before they plow it again. The graſs is ſo good, that they commonly mow it for hay the firſt year; it always abounds very much with the white-flowered clover. If the graſs grows but ſhort, it is the farmer's intereſt to feed his cattle upon it, and it will turn to as good account this way, being very ſweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk. *Mortimer's Huſbandry.*

SAND-*Flood*, a terrible diſaſter incident to the lands of Suffolk, and ſome other parts of England, which are frequently covered with vaſt quantities of ſand, rolling upon them like a deluge of water, from ſandy hills in their neighbourhood.

Violent winds break through the turf that covers theſe hills, and then the ſand, lying looſe and naked, is ſoon carried down upon the plains, where it covers and buries the graſs, and in a very little time eats through the light turf, and mixing itſelf with the ſand underneath, becomes one bed of this dry matter never to be covered with turf again. A large body of ſand being thus got together, nothing ſtops its progreſs; but it, at every ſtorm, rolls over more and more ground, ſo that in a few years it extends itſelf a vaſt way, eſpecially where the ground, over which it paſſes, is of the ſame ſandy nature, and only covered with a thin turf.

In ſome parts of Suffolk the ground encourages this change ſo greatly, that a bed of ſand broke looſe from a neighbouring hill, and covering only a few acres, perhaps eight or ten, will, before it has travelled four miles forward, which it does in a ſmall courſe of years, deluge a thouſand acres. It travels down hill faſter than any way elſe, but will not be ſtopped by aſcent, but will move up the ſteepeſt hill, only that it requires more time. The making of fences, in the common way, to keep it out, is vain. It runs through the hedges, and flies over the tops of the banks; and when it reaches a village, in its courſe, will bury the cottages, unleſs preſerved at more charge than they are worth. If will in a very little time beat up to the eaves of a houſe, of the low kind, that are uſually built in a country village, and has often weight enough to break down walls in its paſſage.

The beſt way of ſtopping its progreſs is by hedges of furze, planted one over another, as they become levelled; theſe, if well kept up, will, by degrees, ſtop or divert the progreſs; and ſome who have tried this, with reſolution, after they have had the ſand raiſed twenty feet high, have found it ſtop its increaſe, and then, having manured this adventitious ſoil with dung, found it as good ground as that which made the ſurface before.

About Thetford, the villages were wholly deſtroyed by this about ninety years ago, and the branch of the river Ouſe, called then Thetford river, ſo blocked up by it, that very ſmall veſſels only could go up it, where very large ones uſed before. The river has been of great ſervice in ſtopping its progreſs into Norfolk, where otherwiſe its courſe would have carried it, and its vaſt ſpreading ſideways, in proportion to its going forward, would have made it bury vaſt quantities of land in a few years.

The moſt probable conjecture, as to the cauſe of this ſtrange ſort of deluge in theſe parts of England, is, that this portion of the county of Suffolk lies eaſt-north-eaſt of a part of the great level of the fens, and is by this expoſed to very impetuous winds, which acquire more than ordinary force, by their paſſing through ſo large a tract of country uninterrupted; the ſtorms ſeem to be one great cauſe of the miſchief, and the ſandy nature of the ſoil the other. There are old ſtories, in the country, of ſuits at law commenced among the farmers, for grounds blown out of the owners poſſeſſion; but the people who gain this ſort of wandering land are the greateſt ſufferers. A little ſand ſprinkled by the winds over a tract of land, where there is a bed of ſand under the turf, ſoon eats through that obſtacle; and what was at firſt only a thin coat of ſand, becomes then a deep plain of it, capable of being blown away to the depth of eight, ten, twenty, or more feet, and is carried over every thing in its progreſs before the winds, when once taken up by them. *Philoſophical Tranſactions*, N°. 37.

SAND-*lands, or Sandy-lands*, a term uſed by our farmers to expreſs ſuch grounds as conſiſt wholly of a pure ſheer ſand.

This is of different colours, as white, blackiſh, reddiſh, or yellowiſh, and is very different in its nature, and in the ſize of its particles, ſome being harſher and ſome milder, and ſome very light, ſeeming only to be mere duſt. The grey, black, and aſh-coloured ſand-land are the worſt of all, and generally are found on heaths and commons.

Gravelly lands approach much to the nature of theſe, and thoſe which conſiſt of the largeſt ſtones, and are mixed with the harſheſt ſands, are of all the moſt barren.

The propereſt plants for arable land, of this kind, are white oats, rye, black wheat, and turneps. The natural produce, in weeds, is quick graſs, ſorrel, broom, furze, fern and heath.

The beſt manure for them is either marl, or ſuch clay as will break with the froſts. Cow dung is alſo a good manure for theſe lands, and many uſe with ſucceſs chalk, mud, and the half rotten ſtraw from dunghills.

When the farmer has a mind to raiſe corn on theſe lands, he muſt order them the ſame as they do the clays; but where they are over-run with broom, furzes, and ſuch ſort of weeds, marle is to be laid on in great quantities. This is the practice in Staffordſhire, and by it they rid themſelves of theſe troubleſome weeds, and procure good crops of corn, though at ſome expence.

The firſt ſowing of this land is with black wheat, and for this they make three fallowings in winter, and ſtir them in the May following; at this time they ſow them, allowing one buſhel of ſeed to an acre, which generally yields them ſixty again. Then once plowing theſe lands, after this crop is off, they are fit to ſow rye on.

In Oxfordſhire, they ſeldom give theſe lands more than two fallowings for wheat, except they are very much over-run with weeds; and they eſteem the white and Lammas wheat the moſt agreeable for this ſort of land, and then after a fallow rathripe barley. They afterwards generally fallow them every other year, and reckon them unfit for beans and peas, though they ſometimes ſow them with winter vetches. If they ſow peas on them, they eſteem the rathripe kinds the beſt.

In Herefordſhire, they are much ſubject to moſs growing upon their ſandy lands, and they make a great improvement by burning it on the ground, and mixing the aſhes with lime, which they plow in.

They generally ſow them with rye after this manure, and that yields a very great increaſe upon them, and brings on a very good kind of graſs, if they are laid down after a crop or two. *Mortimer's Huſbandry.*

SAP, a juice furniſhed by the earth, and changed into the plant, conſiſting of foſſil, ſaline, aerial, and other particles from putrified animals, vegetables, &c.

This juice enters the plant in form of a fine and ſubtile water; which the nearer it is to the root, the more it retains of its proper nature; and, the farther from the root, the more action it has ſuſtained, and the nearer it approaches to the nature of the vegetable.

Conſequently, when the juice enters the root, the bark whereof is furniſhed with excretory veſſels, fitted to diſcharge the excrementitious part, it is earthy, watery, poor, acid, and ſcarce oleaginous at all.

In the trunk and branches it is further prepared, though it ſtill continues acid; as we ſee by tapping or perforating of a tree in the month of February, when it diſtils a watery juice apparently acid.

The juice being here carried to the germs or buds is more concocted; and here, having unfolded the leaves, theſe come to ſerve as lungs for the circulation and further preparation of the juice.

For theſe tender leaves, being expoſed to the alternate action of heat and cold, moiſt nights, and hot ſcorching days, are alternately expanded and contracted, and the more on account of their reticular texture.

By ſuch means is the juice ſtill further altered and digeſted, as it is further in the petala or leaves of the flowers which tranſmit the juice, now brought to a further ſubtility, to the ſtamina: theſe communicate it to the farina or duſt in the apices, which is, as it were, the male ſeed of the plant, where having undergone a further maturation, it is ſhed into the piſtil, which performs the office of an uterus or womb; and thus, having acquired its laſt perfection, it gives riſe to a new fruit or plant.

The root or part whereby vegetables are connected to their matrix, and by which they receive their nutritious juice, conſiſts of an infinite number of vaſa abſorbentia, which, being diſperſed through the interſtices of the earth, attract or imbibe the juices of the ſame: conſequently, every thing in the earth that is diſſoluble in water, is liable to be imbibed; as air, ſalt, oil, fumes of minerals, metal, &c. and of theſe do plants really conſiſt.

Theſe juices are drawn from the earth very crude; but by the ſtructure and fabric of the plant, and the various veſſels they are ſtrained through, become changed, further elaborated, ſecreted, and aſſimilated to the ſubſtance of the plant.

SCAB, a diſeaſe incident to ſheep, chiefly occaſioned by a tedious length of wet weather.

"I imagine, ſays Mr. Veſey, your readers will not be diſpleaſed if I ſhould, with your aſſiſtance, communicate to them a remedy for this diſorder, which I have ſeveral times tried, and almoſt always found to anſwer extremely well.

"Some men, whom I have known to breed and feed a great number of ſheep, have been groſly miſtaken in their comprehenſion of the nature of this diſtemper, which they raſhly judged to be merely cutaneous; whereas, when a ſheep has the ſcab, the blood is always more or leſs affected by it: therefore the outward applications, which are in general alone reſorted to for a cure, do for the moſt part more hurt than good, by driving in the eruption, and making it fix on the internals, thereby often occaſioning the death of the animal.

"Now the true way to treat this diſorder is, firſt to give the animal ſomething inwardly to drive out the eruption; then comes, with propriety, the outward application, which completes the cure by killing the ſcab.

"When a farmer has any of his flock afflicted with the ſcab, let him attend to the directions which follow.

"Take a gallon of ſoft well or pond water, which divide into two equal parts: in one of theſe parts diſſolve eight ounces of old hard ſoap; to which when it is diſſolved, add two ounces of ſpirits of hartſhorn, and ſeven ounces of common ſalt, with four ounces of roll brimſtone, beat to a fine powder and ſifted: then take the other part of the water, in which put two ounces of tobacco leaf, and one of white hellebore root: boil this ſecond part till you have a ſtrong infuſion, after which ſtrain it clear from the leaves and roots.

"When you have got thus far in the proceſs, take that part of the water, firſt mentioned, and ſet it over the fire; let it boil for about half an hour, keeping it continually ſtirring with a wooden ladle during that time: in the mean time heat again the other part, in which the tobacco and hellebore were infuſed; and when it is hot, mix the two parts gradually together over the fire, keeping the mixture continually ſtirring till it is taken off the fire, which ſhould be in about a quarter of an hour: when it

is

is quite cold, let it be put into a ſtone bottle, in order to its being kept in a cool place for uſe.

"Then take four quarts of new ale or beer: put into it twelve ounces of common ſalt, two ounces of bay ſalt, and eight ounces of pounded nitre, together with twelve ounces of pounded roll brimſtone: ſet them over a gentle fire, and when the ale boils, take off the ſcum; let it boil for about half an hour; after which ſet it by till it is cold, and put it into a ſtone bottle for uſe.

"When you are ſo far prepared, take one quart of ale, ſet it on the fire; mix into it by degrees, three ounces of flour of brimſtone; when it is juſt ready to boil take it off the fire, and let it ſtand to cool; and when it is only blood-warm, give this quantity inwardly to three ſheep, which is to be repeated every ſecond day till they have had three doſes. This will drive out the diſorder, when the firſt mixture is to be rubbed on the diſtempered parts: and two days afterwards the ſecond, and ſo alternately for about eight or ten days, till the cure is effected: ſometimes two rubbings will be ſufficient.

"I muſt obſerve, that all theſe mixtures will be beſt boiled in well-glazed earthen or iron pots." *Muſeum Ruſticum*, *vol.* II. *page* 173.

"The two greateſt enemies the ſheep, ſays another ingenious gentleman, or at leaſt their wool (which is the moſt valuable part of them) have, are the ſcab and fly. I believe they deſtroy more wool than all the other diſeaſes incident to that animal.

"Mr. Veſey has given us an approved remedy for the ſcab, and at the ſame time enters ſomewhat into the nature of that diſtemper. For my own part, I have not preſumption enough to look into firſt cauſes; ſecondary ones are all I aim at: I always took nature to be a wiſe inſtructor, and the ſureſt guide; but if we will hobble out of the way ourſelves, ſhe is not to blame.

"I agree with Mr. Veſey, that in this, and every other diſtemper a ſheep labours under, the blood is more or leſs affected and diſturbed; which diſturbance, if I am not miſtaken, the faculty call a fever; therefore it muſt be always conſidered, that a fever is no more than a ſtruggle of nature to get rid of ſome enemy in the blood, by throwing it out by ſome of the outlets of the body, namely, by ſweat, urine, or ſtool; or upon the ſurface of the ſkin; and then ſhe ſeems to ſay, I have thrown the diſtemper out to your view, and there deſtroy it by proper applications.

"It ſurely is not ſcab until it is thrown out upon the ſkin; and when it is thrown out, what avails it giving internal remedies, to do that which nature has done before? If it be out, there's your ailment; and I think, gentlemen, it is an axiom in phyſic, that when a diſtemper is once known, it is half cured: if it is only coming out, my advice would be, not to diſturb nature, who is always acting for our good, in a wiſer and better manner than we can do ourſelves: ſhe ſometimes indeed is too weak for her office, and ſometimes too ſtrong; in the one caſe ſhe is to be properly aſſiſted, and in the other, prudently reſtrained; and when we do more or leſs, the effects are nenerally fatal. I hope this will ſatisfy Mr. Veſey, that he is not altogether in the right, any more than his neighbours.

"To cure an illneſs with a few medicines, is as commendable, as to ſay a great deal in a few words. One great obſtacle to Mr. Veſey's treatment of ſheep with ſcab, is its being too compound, troubleſome, and laborious, ſetting aſide the expence, and, where there are a great number of ſheep, hardly to be practiſed. I would have all remedies for the ailments of ſheep be as ſimple as poſſible; and to be obtained and prepared with as little trouble; for certain I am, gentlemen, when it is otherwiſe, many will let their flocks go neglected, or at beſt leave them to a ſlovenly ſhepherd, who knows very little of the matter; and when clip-day comes, when the poor creatures are out of their wool, (if they had any on before) what a ſight preſents itſelf to view! moſt parts of their ſkins being one continued ſcab, and other parts eat quite through, and deep into the fleſh, by the maggot: this I have ſeen at clip-day, and may ſpeak it; but what muſt I alledge it was owing to? Sorry am I to ſay, to the over credulity of the maſter, who thought he had a ſhepherd who knew every thing; but the event proved the contrary.

"You muſt not be ſurpriſed when I ſay, what will deſtroy the fly, will alſo cure the ſcab, with little or no alterations: mercury is a mortal foe to both; and the remedy for the fly is as follows.

"Take of good corroſive ſublimate, half an ounce; diſſolve it in two quarts of rain water; to which add a gill of ſpirits of turpentine: this is the whole of it, which muſt be uſed in the following manner.

"When the ſheep is ſtruck, the ſhepherd muſt make a circle round the maggots with ſome of the water, by dropping it out of a bottle: this prevents them getting away, for they will not come near the water: then he muſt ſhred or open the wool within the circle, and drop a few drops of the water amongſt them, and rub them about with his finger, and there leave them, for they will all die preſently.

"I ſpeak this from my own certain knowledge, and many others in this part of the country (Iſle of Ely) can do the ſame.

"To a quart of the above water I add a pint of the ſimple lime-water of the London Diſpenſatory; and I declare it from experience, there is no more certain cure for the ſcab than it: I am ſure it is the cleaneſt, the ſooneſt prepared, and, when ſo, the cheapeſt; which are inducements, I think, ſufficient to have every countryman make uſe of it." *Muſeum Ruſticum*, *vol.* II. *page* 369.

SCRATCHES, a diſtemper incident to the heels of horſes.

It has ſo much affinity with the greaſe, and is ſo often a concomitant of that diſeaſe, that the method of curing the ſcratches may be ſelected from that article.

The parts affected ſhould be firſt covered with the linſeed and turnip poultice, having a little common turpentine added to relax the veſſels; the green ointment may then be applied to promote the diſcharge, when the ſcratches may be dried up with the ointments and waſhes recommended in that article. *See* GREASE.

It is beſt afterwards to keep the heels ſupple, and ſoftened with curriers dubbing, which is made of oil and tallow. This will keep the hide from cracking, and be as good a preſervative as it is to leather; and by uſing it often before exerciſe, will prevent the ſcratches, if care is taken to waſh the heels with warm water, when the horſe comes in. When they prove obſtinate, and the ſores are deep, uſe the following; but if any cavities or hollow places are formed, they ſhould firſt be laid open, for no foundation can be laid for healing, till you can dreſs to the bottom.

Take Venice turpentine four ounces, quickſilver one ounce; incorporate well together by rubbing ſome time, and then add honey and ſheeps ſuet, of each two ounces.

Anoint with this once or twice a day; and if the horſe is full or fleſhy, you muſt bleed and purge; and if the blood is in a bad ſtate, the alteratives muſt be given to rectify it. *Bartlet's Farriery, page* 294.

SCYTHE, SITHE, *or* SYTHE, the inſtrument uſed in mowing, being a crooked blade joined at right-angles to a long pole. *See the article* MOWING.

SEAGRIM. *See* RAGWORT.

SEAM, tallow, greaſe, hogs-lard.

SEAM *of Corn*, a quarter, or eight buſhels.

SEAM *of Wood*, a horſe load of wood.

SEAR, dry; oppoſed to green: ſpoken of wood.

SEARCHER. *See the article* BORER.

SEAVES, ruſhes.

SEAVY *Ground*, ground over-run with ruſhes.

SEED, the product of a plant, whereby the ſpecies is propagated.

The choice of the ſeed intended to be ſowed is an object of greater importance than many farmers ſeem to imagine. It is not ſufficient that the fineſt grains be choſen for this purpoſe, unleſs they are likewiſe very clean. Such wheat is not difficult to be had from land cultivated according to the principles of the New Huſbandry; but we ſeldom find corn intirely free from ſeeds of weeds when it has been raiſed in the common way.

It is natural to ſuppoſe, that the grains of ſtinted and ſickly corn neceſſarily partake of the weakly diſpoſition of the plant which produced them, and that their productions cannot be ſo fine as thoſe which grow from the ſeeds of ſtrong and healthy plants. For this reaſon Mr. Tull adviſes to take the ſeed corn from a richer ſoil than that in which it is to be ſowed, and rather from ground in perfect tilth, than from land which has been leſs carefully cultivated. This ſeems to be very right (though the contrary opinion is almoſt generally received), becauſe more may reaſonably be expected from the productions of a fine good ſeed, which are full of vigour and well conditioned, than from a poor weak plant.

M. de Chateauvieux, who often ſowed with no other intention than merely to try, for the benefit of mankind, at what time, in what manner, and in what condition it is beſt to ſow wheat, found that this corn ſprouted pretty well even when ſowed ſo green that it had not yet loſt its milky quality; but thinks it much more adviſeable to ſow none but what is thoroughly ripe; becauſe the ſeed has then attained its full perfection, from whence we may moſt certainly expect the beſt and ſtrongeſt plants.

"The wheat, ſays he, which has been reaped in a warm dry year, ſeems to me fitter for ſowing, than that which has been gathered in a cold wet ſeaſon: for in ſuch a time as this laſt, all the productions of the earth are leſs good; their taſte is leſs ſavory; and as that corn in particular in which there is moſt moiſture, is moſt difficult to keep, I infer from thence that the formation of its grain muſt be leſs perfect. I ſhould therefore prefer wheat a year old, provided the year it was gathered in was warm and dry, to that which may have juſt been gathered in too rainy a ſeaſon: for the ſame reaſon, I always chooſe for ſowing, wheat of the growth of my high grounds, rather than that which has been produced in flats. The benefit accruing from all this care, may, perhaps, not be extremely great; but at the ſame time it does not coſt any thing. Let us do in agriculture what is done in all manufactures, where the very ſmalleſt profits, the very leaſt ſavings, are not neglected. Thoſe ſmall articles, often repeated, make large ſums in the long run, and are a real gain.

"Another thing, of greater conſequence, firſt made known to me by chance, but ſince confirmed by repeated experiments, always attended with the ſame ſucceſs, I ſtrongly recommended as extremely ſerviceable to the firſt ſprouting of the ſeed. In my experimental ſowings, I commonly uſed wheat taken from the heap in the granary; and likewiſe, frequently, corn picked out of the ears the moment before I ſowed it. I counted exactly the grains of both ſorts, and ſuppoſe that few will think there could be any difference in their productions. Yet I found a conſiderable one. What was picked out of the ears always roſe extremely well; ſcarce a grain of it ever miſſed; whereas numbers of thoſe which were taken from the heap, never ſprouted at all. I did not perceive this difference at firſt; but at laſt it ſtruck me. I relate the fact as it is, without pretending to account for the cauſe of this difference, which would lead me into too long a digreſſion. The experiment itſelf may be of real uſe, by ſhewing us, that inſtead of threſhing the wheat intended for ſeed at any time, without diſtinction, it ought not to be threſhed till a very few days, at moſt two or three, before it is ſowed. A few hands will be able to ſupply the ſeeds-men with as much as they will want: nor will this method, which may be a means of ſaving ſomewhat in the ſeed, be attended with any extraordinary expence.

"Perhaps too this practice may be attended with a very valuable advantage. I have not indeed yet made the trials neceſſary to ſatisfy myſelf of what I imagine; but my deſire to be of ſervice to the public induces me to mention it, that the lovers of agriculture may reflect upon it, and try ſuch experiments as will clear up my conjectures.

"Threſhing the ſeed only juſt before it is ſowed may poſſibly, in ſome meaſure, or perhaps intirely, prevent the cauſe of ſmut in wheat. By this I mean, that the ſeed which has not been mixed with ſmutty corn, or any way infected by its black powder, will be exempt from that diſtemper. Not that I take black powder to be abſolutely the original cauſe of this diſtemper in corn; but I believe it is very capable of communicating it to grains which are ſound.

"That nothing may be neglected which can be of any ſervice to the ſeed, great care ought to be taken in threſhing the corn, eſpecially in the manner that buſineſs is commonly performed, with flails, upon the barn floor: for a great number of grains are frequently ſo much bruiſed thereby, that it is impoſſible they ſhould ever grow. If the wheat thus threſhed for ſeed is not thoroughly dry and hard, the miſchief is ſtill greater; much more of it being then abſolutely cruſhed by the flail.

"As ſowing in drills requires leſs ſeed than is uſed in the common method, it will be the eaſier to execute there an operation which might be too long and troubleſome for ſo great a quantity as is uſed in the old way. The method which I adviſe, and which I have practiſed, is this. Let one or two beams, two feet and a half, or three feet thick, be laid a-croſs the barn floor; let the threſhers ſtand on each ſide of the beam, and take out of looſe ſheafs of wheat, one of which ſhould be placed behind every man, a handful at a time, and give it two or three ſtrokes againſt the

the beam. This will bring out a great deal of grain, which is to be reſerved for ſeed. The ears thus ſhaken may be bundled up again, and afterwards threſhed out with the flail, for other uſes. This method is not ſo tedious as ſome may imagine: we are ſure that not a grain is bruiſed; and thoſe are the moſt perfect which drop out thus. I think I may compare this operation with what is done in the making of wine, where the firſt running is always the higheſt flavoured and beſt.

Another excellent way to ſeparate the fulleſt, and conſequently heavieſt grains, which are undoubtedly the fitteſt for ſeed, from thoſe which are of leſs value for that purpoſe, and at the ſame time to clear them from many ſeeds of weeds, is, to make a ſtout man, with a broad wooden ſhovel, throw the corn with all his force towards an oppoſite corner of the barn, or rather of a large boarded hall, which generally is the fitteſt for this work. All the light ſmall, ſhrivelled grain, unfit for ſowing, and the ſeeds of cockle, darnel, &c. not being ſo heavy as the ſound ſolid corn, will fall ſhort, and lie neareſt to the man who throws them; while ſuch as are large, plump, and weighty, out-flying all the reſt, are ſeparated widely, and may eaſily be gathered up. Experience will ſhew the vaſt advantages of ſowing ſeed thus choſen.

The uſe of ſteeps was introduced very early into huſbandry, not only as a means of preſerving corn from ſeveral diſtempers to which it is ſubject, but alſo with a view to render the ſeed more fruitful. That ſome of them have ſometimes anſwered the former of theſe intentions is undeniable: but with regard to the latter, much ſtronger and oftener repeated evidences than any that have yet been produced, are ſtill wanted to confirm their boaſted efficacy. I ſhall however, give a conciſe account of ſome of the moſt famous of both kinds; with this previous obſervation, that even ſuch of them as have not ſucceeded in ſome caſes, through cauſes perhaps unknown to us, may poſſibly do well in others, when tried with proper judgment and attention. Experiments of this kind ſhould by all means be continued on a double account; firſt, to take off a prejudice which ſeems to gain ground, though it be not founded on any rational principle; and next to be well aſſured whether theſe preparations do, or do not produce any ſenſible effect. Experiments ſeldom prove uſeleſs to careful accurate obſervers. If they do not always anſwer the end propoſed, they at leaſt ſometimes lead the way to other important diſcoveries.

The Romans had their lees of oil, decoction of cypreſs leaves, juice of houſe-leek, &c. on which they have beſtowed full as much commendation as they merit. Lord Bacon ſeems to have been the firſt who paid any attention to this ſubject in England: but he has only pointed out the path to others: nor do I know any author who has yet given us a ſet of experiments with this view, long enough continued abſolutely to determine what effects ſome kind of ſteeps may have towards rendering grain more fruitful.

Van Helmont, and, ſince him, the authors of the Maiſons Ruſtiques, have given many receipts for ſteeps, which they vaunt exceedingly, as increaſing the fruitfulneſs of the ſeed ſteeped in them. But at the ſame time that they recommend theſe receipts, they adviſe ſowing the corn thinner than uſual; generally one third leſs; a circumſtance which, alone, will add greatly to the crop, as very many experiments, and particularly all the good trials of the new huſbandry, have evidently demonſtrated. That the compariſon may be juſt, all circumſtances ſhould be alike, as to the goodneſs of the ſoil, the quantity and quality of the ſeed, &c.

M. Duhamel, to ſatisfy himſelf whether any benefit does ariſe from the uſe of ſteeps, by way of giving the ſeed a greater degree of fruitfulneſs, tried the following experiment. He infuſed ſome good wheat in a lye of dung, mixed with lixivial ſalts, nitre, and ſal ammoniac, and ſowed with this grain two beds in his kitchen garden, dug with a ſpade. One of the beds was ſowed very thick, and the other very thin. At the ſame time he ſowed two other beds, exactly like the former, with ſome of the ſame ſeed, not ſteeped, one thick, and the other thin. At harveſt time the beds ſowed with the ſteeped ſeed were ſo exactly like the others, that it was impoſſible for the eye to diſtinguiſh between them.

A gentleman in his neighbourhood followed exactly the directions given in the Maiſons Ruſtiques, in the uſe of one of their boaſted receipts, which is there ſaid to be of ſuch efficacy, that the land need be plowed but once for wheat prepared with it. He did ſo; and his crop was ſcarce worth reaping.

On the other hand, M. Duhamel mentions his being informed by M. Peyrol, many years ſecretary to the intendant of Auvergne, that he had made ſeveral experiments in imitation of thoſe mentioned in the abbé de Vallemont's famous book. In the month of May 1755, he planted in his garden (an indifferent ſoil, in a hot expoſition,) four ſmall cabbages, which then had only four leaves. In September following, the ſame cabbages were ſix feet and a half in circumference. Some plants of red wheat, tranſplanted into a bed dug very fine in his garden, bore one hundred and thirty ears a piece, each of which contained from forty to eighty grains. Some plants of white wheat, tranſplanted at the ſame time, produced one hundred and twenty ears, each of which had from thirty to forty grains. Two grains of red wheat, ſowed in the ſame bed, and not tranſplanted, produced each of them one hundred and forty ears, which contained ſix thouſand grains. Five plants of red wheat, diſtance from one another ſix inches, did not branch ſo well, being too cloſe together: but each of them produced from forty to fifty ears, which contained from forty to ſixty grains. Rye, which branches leſs than wheat, produced from thirty to thirty-five ears, each containing from ſixty to ſeventy grains: and the barley of that country, which branches but little, produced however from ſixty to eighty ſtalks, though the ſeed of this laſt had not been ſteeped in any liquor before it was ſowed.

The author of theſe experiments judiciouſly obſerves, that they muſt be repeated and varied, before it can be made to appear that the extraordinary increaſe is owing to the ſteep.

This celebrated liquor of the abbé de Vallemont is made as follows.

Put into a tub, expoſed to the ſouth, one buſhel of horſe-dung, the ſame quantity of cow-dung, half a buſhel of pigeon's-dung, as much ſheep's-dung, as much aſhes, three gallons of ſmall pricked wine, two pounds of ſalt-petre, and as much water as will ſufficiently dilute the whole, ſo as to make it thin enough for uſe. Every time that any of this liquor is taken out to ſprinkle the plants, it is filled up again with water; and as it may be too ſtrong at firſt, it may be weakened accordingly.

It is eſſential to obſerve, that M. Peyrol added to this infuſion frequent digging; for the ground was dug five times.

times between the plants of wheat: and he obſerved that each digging ſenſibly gave freſh vigour to the plants, which grew to the height of ſix feet.

M. Donat, another of M. Duhamel's judicious correſpondents, made trials of theſe mixtures, from the uſe of which ſo much is promiſed: but ſays he thinks them of no other ſervice, than to amuſe the curious, who do not regret expence. As the authors of them boaſt that all kinds of ſoils, whether good, bad, or indifferent, well or ill plowed, reſted or not reſted, will produce ten times more than in the common way; this gentleman ſowed a large extent of ground, ſome good, ſome bad, ſome well, and ſome ill plowed, &c. He made the ſteep himſelf, was preſent when the ſeed was ſowed, and took care that no circumſtance was neglected. But notwithſtanding all his care, his crop was far from anſwering their promiſes. The good, well cultivated ſoil, produced fine wheat; but not extraordinary in point of quantity. The only advantage was in the ſaving of the ſeed. The poor ill cultivated land, and that which had not been reſted, produced very little grain: and the very bad ſoil, none at all. Theſe experiments convinced M. Donat, that the ſureſt means of obtaining good crops, is, to have the ground in good condition. This is the principle on which the New Huſbandry is founded: nor indeed does it offer any thing marvellous, or contrary to the moſt ancient precepts of good huſbandry.

If there be in any of theſe ſteeps, or preparations, a more than common virtue, by which the grain infuſed in them is rendered more prolific than it would otherwiſe be, poſſibly ſome ſuch benefit may accrue from the following practice, which is recommended by the author of the New Syſtem of Agriculture.

"Take, ſays he, the corn which is intended for ſowing, and throw it, by a buſhel at a time, into a large veſſel full of water: let a man ſtir it with a ſtaff, as violently as he can, for a conſiderable while together, and then, giving it a little time to ſettle, ſkim off all that ſwims upon the ſurface: repeat this till no more riſes; then take out the corn which has ſunk to the bottom, and lay it by for ſeed; proceeding in the ſame manner till you have your intended quantity. After this, make a brine of bay-ſalt and rain-water, ſtrong enough to bear an egg. Steep the ſeed corn in this liquor during thirty hours; for leſs time will not have any effect: then take it out, ſpread it upon a ſmooth floor, ſtrew over it a good quantity of fine-ground powder of ſlaked lime, and ſweep the whole up and down till each grain leaves clinging to another, and becomes, as it were, perfectly candied with the lime. It is then fit for ſowing; and will infallibly produce a very abundant crop." Some farmers vary this ſteep, by adding to it a mixture of pigeons, or other dung; and in moſt parts of France, where this receipt is known, they omit the ſalt; perhaps becauſe it is too dear in that country, and ſteep the wheat in lime-water. For this purpoſe they put it into baſkets, and carefully ſkim off all that ſwims on the top, moſt of which would not ſprout, and is only fit to feed fowls.

The ſociety of improvers in the knowledge of agriculture in Scotland, call the following a very promiſing receipt for multiplying corn: but as no experiment that we know of, duly attended to, has yet confirmed that ſurmiſe, we can only ſay, that it may not be wrong to give it ſuch farther trials as will not hurt the experimentor, whether they do or do not ſucceed: a rule which ſhould be conſtantly obſerved in all experiments.

"Take as much water as will fully cover the quantity of grain you intend to uſe; add thereto a reaſonable quantity of a mixture of horſe, cow, and ſuch other dung as you can conveniently get, ſo as not to make the water too thick: add likewiſe for every boll (four buſhels) you are to ſteep, about a peck or a ſixteenth part of the ſame ſort of grain as you are to ſteep. Boil all theſe till the grain is reduced to a pulp; keeping the kettle or cauldron cloſe covered, to retain the ſteam. When the boiling is over, pour off the water, and diſſolve in it a pound of nitre, or ſalt petre, to every four buſhels of corn: then, while it is luke-warm, infuſe your corn for three days, after which, drain off the water, ſpread the grain on the floor, mix it with a ſufficient quantity of ſea-ſand, (if ſuch can be conveniently had), and laſtly, with lime, to dry it, as is uſually done in other caſes."

"It ſeems reaſonable to think," ſay the abovementioned ſociety, "that nothing can be more natural for impregnating grain, than the ſtrength and eſſence of itſelf. But, ſince nitre is added, it is beſt to be cautious; for it has been found by experience, that ſalts, though they have the virtues mentioned, kill or deſtroy the vegetative powers, when the application is immoderate, either with reſpect to the quantity, or the time the grain is ſteeped; ſo that there has often been a neceſſity to ſow over again with the ſame, or ſome other grain. To make the better judgment concerning this critical affair, the nature and condition of different grains are carefully to be conſidered; but the moſt certain knowledge and direction are to be obtained by a courſe of obſervations and experience. Mean while, it is beſt to obſerve the maxim, avoid extremes."

In Mr. Houghton's collection of papers relative to huſbandry and trade, are ſeveral experiments on the ſteeping of wheat and barley in a liquor which is there ſaid to have occaſioned a very great increaſe, and is thus made." "Take a quantity of rain-water, and diſſolve in every gallon of it two pounds of ſtone-lime: let it ſtand two or three days, ſtirring it three times a day: then pour off the water into another veſſel, and add to every gallon of it about four ounces of ſalt-petre, and one pound of pigeons dung: mix them well together, by ſtirring them three or four times a day, and then ſtrain off the liquor to keep for uſe." Mr. Everard, who communicated this receipt to Mr. Houghton, ſteeped a handful of wheat in a quart of this liquor, where he let it infuſe eighteen hours: he then took it out, and laid it to dry in the air for the ſpace of one day; and then ſteeped it again in the ſame liquor for about twelve hours, dried it as before, and ſteeped it again a third time, about ſix hours, after which he planted it in his garden, which was but common earth, ſetting it by ſingle grains, about ten inches aſunder, and a finger's length in depth. He could not remember whether every grain ſprouted, but thought that very few failed. Thoſe which did grow, produced an extraordinary increaſe, ſeveral of them yielding from ſixty to ſeventy, ſome of them eighty ſtalks with very large ears full of fine plump corn: many of the ears were ſix inches long, and contained ſixty grains: none had leſs than forty.

He alſo ſteeped peas and beans in the ſame liquor; but could not ſay whether their having been ſteeped too long was the cauſe that none of them came up: but he took the thick ſediment which remained after the liquor was ſtrained off, mixed it with four times the quantity of earth, let it lie all winter in a gravel walk, ſouth of a codlin hedge, then made a row of holes, about four inches diſtant, put a handful

handful of the mixed earth into each hole, with a pea upon it, and covered it with common mould. The peas ſprouted well, ran up the codlin hedge to the height of about nine feet, ſhot out branches in ſeveral places, like vines, and bore ſo many well filled pods, that he judged he had above a buſhel from about three or fourſcore ſeeds.

He tried alſo an experiment on wheat infuſed in lime-water alone, ſome in brandy alone, and ſome in brandy and lime-water mixed, and had a great increaſe from each grain. With ſome of the liquor made with ſalt-petre, lime, and pigeons dung, he watered ſeveral trees in his garden, and found them grow and flouriſh much faſter than any other of the ſame kind which were not watered in that manner. He alſo ſteeped barley in the ſame liquor, and found its increaſe equal to that of wheat.

Whether there be, or be not, any kind of prolific efficacy in theſe, or any other ſteeps, of which great numbers are pompouſly recommended, and which proper experiments can beſt determine; they are at leaſt ſo far ſerviceable to the ſeed corn, that they clear it from filth, from many ſeeds of weeds, and from ſuch poor light and diſtempered grains as are not fit for ſowing, and prepare it in ſuch a manner, that, being already well moiſtened, it will ſhift much better than abſolutely dry grain, in caſe a drought ſhould enſue after it is ſowed.

This thorough cleanſing of the ſeed may probably be, in a great meaſure, the reaſon why corn ſo prepared is leaſt apt to produce ſmutty ears. All the lyes generally made uſe of, certainly preſerve the plants from mouldineſs, and that in which lime is a principal ingredient ſeems to be one of the moſt effectual. But as this part naturally leads to the diſtempers of corn, another very intricate, but highly intereſting ſubject, we ſhall reſume it under that head, to which it properly belongs; and give in the mean time M. Duhamel's farther opinion concerning the pretended prolific virtues of infuſions, with ſome late experiments relative thereto, as delivered in the ſixth volume of his excellent Treatiſe on the Culture of Land, publiſhed laſt year.

We liſten readily to the marvellous, eſpecially when it promiſes any great and ſingular advantage. Such was the abbé de Vallemont's prolific liquor, by means of which the huſbandman was to reap vaſt crops, without manuring, or ſcarcely plowing his land. He was only to ſoak his ſeed in this admirable liquid, which was to open, ſtrengthen, and amazingly fertilize the germe. Improbable as this doctine is, it was greedily received.—It is known, that a ſeed contains in that part of it which is called the germe or bud, the embryo of a plant, that is to ſay, a plant in miniature, and that the reſt of the ſeed ſerves to feed the young plant, or plantule, till it acquires roots which draw its farther nouriſhment from the earth. As ſoon as theſe roots ſpread, the ſeed is exhauſted, and there remains only its then uſeleſs huſk. What benefit then can be derived from prolific liquors? Perhaps they may render the nutritive ſubſtance of the ſeed fitter to ſupport the young plant, which in conſequence thereof, may appear ſomewhat more vigorous at firſt, and till it has ſtruck out roots: but from the time of its producing thoſe roots, it ceaſes to ſubſiſt upon the lobes of the ſeed. Can it be imagined that a ſingle atom of any prolific liquor exiſts at the diſtance of four or ſix inches from the plants in the earth, where its roots are ſpread, and from whence they draw their ſubſiſtance? Yet, ſuch is the fondneſs of men for projects of this kind, de Vallemont's mixture was extolled as a wonderful diſcovery, indued with a magnetic virtue capable of attracting from the boſom of the air certain principles, which probably do not exiſt in it, and numbers of receipts have been deviſed for making prolific liquors. Writers upon agriculture have ſtuffed their books with them, and vaunted their miraculous effects. A deſire to ſee theſe mighty promiſes fulfilled, paved the way for their reception, and ill made experiments have given a ſanction to the error.

A little corn, impregnated with theſe pretended prolific liquors, has been planted grain by grain in a garden, and its extraordinary increaſe has immediately been imputed to the ſteep. I myſelf was deceived by ſuch trials: but when I extended them to three or four acres of ground, this great fertility no longer took place, and I began to doubt the efficacy of theſe boaſted ſpecifics. About the ſame time, I ſaw a ſingle grain of barley produce 230 ſtalks, without any preparation, and was informed by the Rev. Dr. Hales, that another grain of barley had in like manner, produced one hundred and fifty-four ears. From hence I concluded, that the prodigies of vegetation ſo much vaunted by ſome writers, as the effect of their favourite infuſions, have in fact been owing to the nature of the ſoil, to good culture, and to the grains being at ſuch diſtances from each other, that their roots have had room to ſpread, and thereby collect a great quantity of food. I then had recourſe to new experiments, which confirmed me in this opinion.

We ſee in the Political State of England, that a grain of wheat which grew by chance on a bed of onions, and had not received any preparation, produced 5600 grains. Upon which the author of that work remarks (as indeed I had done before in regard to the former of the above-mentioned productions) that we muſt not from thence infer that the country where ſuch a thing happens is naturally more fertile than another, or the method of agriculture commonly practiſed in it better than elſewhere; for that the cauſe of theſe prodigious growths is, that the grains ſtand ſingle and in a good ſoil; that the only conſequence which can be drawn from thence, is that the New Huſbandry comes neareſt to that ſtate in which theſe ſurpriſing growths are produced; that it certainly muſt increaſe the product of the crops; and that it will probably require leſs ſeed than is uſed in the common way.

Though it was pretty well proved by our experiments, that good culture and proper manures contribute more effectually to the increaſe of crops, than all the boaſted prolific liquors; yet ſeveral perſons, out of zeal for the public good, have publiſhed, ſome the advantages which they think ariſe from the uſe of certain fertilizing ſteeps, and others, receipts for making them.

In this ſpirit, M. de la Jutais has given us a little tract entitled, The true Philoſopher's Stone, according to which, an admirable prolific liquor is to be thus made. Fuſe ſome nitre in an iron veſſel; and when it is hot enough to burn the ſubſtances which are to be added, throw in a ſmall quantity of the ſame kind of ſeed as you intend to ſow: for example, if you would have a prolific liquor for wheat, throw a little wheat upon the nitre; if turnips, put in turnip ſeed, and ſo on. Theſe ſeeds take fire, are conſumed, and incorporate with the melted nitre. Your prolific liquor is then made, and you have only to mix the nitre with water. What reſults from this operation? Nothing more, than that there is in this prolific liquor

liquor a great deal of nitre with a ſmall portion of fixed nitre, or alkaline ſalt: whether this nitre be mixed with wheat, barley, turnip ſeed, or powder of coal, all chymiſts allow that the reſult will be the ſame, and that the ſame liquor might be made by mixing a little alkaline ſalt with a ſtrong ſolution of ſalt-petre. The queſtion is, what effect it will have upon vegetables. To try this fairly, two exactly ſimilar fields ſhould be ſowed, the one with wheat prepared with the prolific elixir, and the other with wheat only limed in the uſual way; taking care to ſow an equal quantity in each field: for the ſingle circumſtance of diminiſhing the quantity of the ſeed, may increaſe the crops in years when the corn does not tiller much, and in good ſoils. Many have been deceived by not attending to this circumſtance. The following are well made experiments.

"M. Delu, after trying M. de la Jutais's eſſence three times, with the moſt ſcrupulous care and exactneſs, thinks it of no ſort of ſervice.

"M. Peirol, whom I mentioned before, communicated to me in 1755, ſeveral experiments which he had made with great care, in order to ſatisfy himſelf whether theſe prolific liquors have any virtue; and thoſe trials made him then hope for ſucceſs. I thanked him for his obliging letters, and exhorted him to repeat the ſame experiments with ſome new precautions which I thought important. He did ſo, with all poſſible care; and it is with real pleaſure that I ſhall give a juſt account of them, becauſe they ſeem to me extremely fit to diſſuade thoſe who wiſh well to agriculture, from putting their truſt in ſuch illuſions. Inſtead of running after an empty ſhadow, they may employ their time in uſeful perquiſitions, by which the public will be benefited.

"M. Peirol ſowed, both in his own garden, and in that of the intendant of Auvergne, 1. many-eared wheat; 2. rath-ripe barley; 3. the common red wheat of the country; and had from each of them an amazing increaſe.

"Each plant of the many-eared wheat, had from fifty to ninety-two ſtalks, and theſe laſt yielded 13800 grins.

"Some of the rath-ripe barley had two hundred and forty-four ſtalks to each plant, and yielded 14640 grains.

"Several plants of the red wheat had three hundred ſtalks; but the grains were eaten by birds.

"Theſe were fine productions: but the moſt important thing to be obſerved here, is that M. Peirol ſowed all theſe different kinds of grain, as well in his own garden, as in that of the intendant, on the ſame day, viz. the 8th of September 1756; part of this corn having been ſteeped in the abbé de Vallemont's fertilizing liquor, while the reſt had not been infuſed at all: yet their productions were quite alike, the ground had been prepared exactly in the ſame manner for the ſteeped and the un-ſteeped grain, and both were equally watered from time to time with that prolific waſh. This laſt circumſtance ſpoils the whole experiment: for who can doubt but that this watering of the plants with impregnations of dung, muſt give them great vigour; even more than a conſiderable quantity of dung itſelf would have done? However, the following experiment is, luckily, without that fault.

"On the 4th of April 1755, M. Peirol divided a pretty large field into five equal parts. The ground was in good tilth, and he ſowed it with barley.

"The firſt part was ſowed with unſteeped barley in rows a foot aſunder.

"The ſecond was ſowed with the ſame kind of barley ſteeped in de Vallemont's liquor, and likewiſe in rows a foot aſunder. Both had a plowing between the rows, towards the end of April.

"The third was ſowed in broad-caſt according to the cuſtom of the country, excepting that a quarter part of the uſual quantity of ſeed was retrenched: but ſtill it was the ſame ſort of barley, and this had been ſteeped in de Vallemont's liquor.

"The fourth diviſion was alſo ſowed in broad-caſt, like the former; with this only difference, that the ſeed was ſteeped in a prolific liquor invented by M. Robineau.

"Laſtly, the fifth part was ſowed intirely in the common way, with the uſual quantity of the ſame kind of ſeed, un-ſteeped.

"The following was the ſtate of theſe five diviſions at harveſt time.

"The firſt and ſecond, which had been ſowed in rows, with only a quarter part of the quantity of ſeed generally uſed in the common way, but prepared for the one by being infuſed in de Vallemont's liquor, and ſowed in the other without any impregnation, were both very fine, and yielded a great deal of grain.

"The third and fourth, which had been ſowed in broad-caſt, with an abatement of only a quarter part of the uſual quantity of ſeed, and where the grain for one had been ſteeped in de Vallemont's liquor, and that for the other in M. Robineau's, were middling, and not viſibly different in any reſpect.

"The fifth ſpot, which had been ſowed intirely in the common way, and with the uſual quantity of ſeed, was the worſt of all.

"Though M. Peirol was prejudiced in favour of prolific eſſences, he nevertheleſs concludes from this experiment, 1. That the un-ſteeped grain uſed for the firſt mentioned portion of the field, having yielded as fine a crop as that of the ſecond which was ſteeped, infuſing the ſeed does not contribute much to make the plants tiller.

"2. That the products of the third and fourth diviſions being quite alike, M. Robineau's ſteep is not better than de Vallemont's.

"3. That the difference between the crop of the fifth, and thoſe of the third and fourth pieces of ground, was probably owing to the different quantity of ſeed.

"4. That the ſuperior beauty of the firſt and ſecond, which ſurpaſſed all the reſt, was occaſioned by the grains being ſo far diſtant from each other, that the roots of the plants had ſufficient room to collect their food, and that the huſbandman was enabled to ſtir the ground between the rows, in the ſpring, by which the vigour of the plants was conſiderably increaſed. All this confirms the advantages of the New Huſbandry; and M. Peirol is ſo convinced of it, that he has ſowed a very large tract of land, near Riom, in the ſame manner as the two firſt parts of the above-mentioned experiment.

"He has likewiſe made another trial of de Vallemont's ſpecific, by planting vines in two different places. In one of theſe, where the ſoil was good, the common practice was followed, and the cuttings ſprouted ſoon: in the other, where the ground was leſs good, each cutting was watered with two quarts of de Vallemont's liquor. Theſe laſt ſhot out later, but then grew with great ſtrength, and retained their leaves a long while. It cannot be doubted but that an infuſion of dung will invigorate plants, and make them grow faſter than they would otherwiſe. The

owners

owners of vineyards are here to conſider, whether the expence of people to do this buſineſs may not be greater than the advantages accruing from it will repay: but it is certain that by thus watering their newly planted cuttings, eſpecially with a ſtrong infuſion of dung, they will ſecure their taking root.

"To ſatisfy myſelf in regard to M. Robineau's pretended prolific liquor, I choſe a piece of ground laid out for wheat, and divided it into three equal parts. One of theſe was ſowed in the common way, with ſeeds only limed, and produced one hundred and ninety-two ſheaves to the acre, which yielded ſixty buſhels of corn. Another was likewiſe ſowed in the common way, with ſeed only limed, but two fifths leſs in quantity than is generally uſed, and produced one hundred and ſixty-eight ſheaves, which yielded fifty-four buſhels. The third part was ſowed with the ſame quantity of ſeed as the firſt, but prepared according to M. Robineau's direction. This produced one hundred and fifty-ſix ſheaves, which yielded fifty-four buſhels of grain. From whence it follows, that his method was not of any ſervice to the crop.

"His liquor, when diſtilled over a very ſlow fire, yields a little brandy; what remains in the matraſs, yields a great quantity of ſalt-petre, and the reſidue is a bitter water which contains a ſmall portion of alkaline ſalt. This is nearly what would be obtained from de la Jutais's liquor.

"M. Vandusfel has alſo tried M. Robineau's prolific liquor, and found it attended with no other effect, than that the field where it was uſed had ſomewhat fewer ſmutty ears than other grounds for which the ſeed had not been ſo prepared. But other ſeed which he ſteeped in an infuſion of dung, aſhes, and lime, produced corn totally exempt from ſmut."

An ingenious correſpondent of the editors of the Muſeum Ruſticum, has given us the following improved method of breeding ſeed-wheat.

"I join, ſays this Eſſex farmer, with many others in opinion, that it is beſt every year to change one's ſeed-wheat, and this has been my conſtant practice: I have had many a weary ride to get ſeed that would pleaſe me, for I am, and always have been, very difficult in this matter.

"I have near two hundred acres of land in conſtant tillage: theſe I divide into three portions, ſo that I have every year about ſixty acres in wheat, ſixty more in barley and oats: and the remainder are either fallow, or in beans, peas, or turnips, &c.

"When I firſt came into my farm, I expended annually, of ſeed-wheat, thirty quarters; for, after the example of my neighbours, I allowed four buſhels of ſeed for every acre I ſowed.

"Theſe thirty quarters often coſt me above ſeventy pounds; and God knows I could ſometimes but little ſpare ſo much money, after the great annual expence of getting in my harveſt.

"Some part of my land differs greatly in its nature from the other: near half my farm is a ſtiff deep clay; what bottom it has I know not, as I never could find it in digging my ditches, &c. the other half is a bed of light ſandy loam; with a gravelly hard bottom.

"This difference in the ſoil of my farm is, on many accounts, a great advantage: particularly, my wheat does not all ripen at the ſame time; I have generally nearly got in that growing on my gravelly land, before that on my clay is fit to cut; and I can beſides plow in all weathers, froſt excepted.

"But not to digreſs too much, I took it into my head that, with proper care, I could breed for myſelf, on my own land, as good ſeed-wheat as any I could buy, if not better; and I determined within myſelf to make the experiment.

"Before I made this experiment, I had reduced the quantity of ſeed I uſed on each acre, to three buſhels, which was a great ſaving to me. I had ſtill occaſion for above twenty quarters.

"My firſt ſtep was to ſelect ten acres of the beſt land I had; five from the heavy, and as many from the light part of my farm: this land was by nature rich and good; it lay on the gentle ſouthern declivity of a hill, and required very little manure: it lay in two little detached fields, at ſome diſtance one from the other.

"When I had prepared this land by a winter and ſummer fallowing, in which time the clayey part was plowed ſeven times, and the light land five times, I had both fields ſown with ſome of the beſt wheat I could procure; that for the heavy land I got from Hertfordſhire, the other from a particular friend who holds a farm in Cambridgeſhire.

"When the ſeaſon for ſowing approached, I was mightily pleaſed with the appearance of my two little plots; for they reſembled the beſt-kept gardens, not a weed to be ſeen, and the earth as fine as garden-mould.

"On this occaſion I did not brine my ſeed, but had it put into a large tub: ſome water was then poured on it, and I made a ſtout labourer, with a ſtiff half-worn birchen-broom, ſtir it very briſkly about for near half an hour; this I imagined would waſh off the ſmut, if any there happened to be: the light ſeeds, which were very few, were ſkimmed off.

"I let the wheat afterwards lie three hours ſoaking, when my man again ſtirred it briſkly with the ſame broom, and immediately poured the water off.

"Whilſt yet wet, the ſeed was ſprinkled in the uſual manner with ſlaked lime, in order to prepare it for ſowing.

"My reaſon for not brining it was, that I thought it would bring it too forward; and I rather choſe to ſow it early, which is, I know, in general, a very good practice.

"In ſowing this land, I, in ſome meaſure, followed Mr. Tull's directions; that is, I ſowed my wheat in rows with large intervals in the following manner.

"I had a furrow opened about a rod from the hedge: in this furrow ſome ſeed was by a careful hand very thinly ſcattered, not ſowed in the common way with a fling of the arm.

"It took up time; ſo I had two ſowers to each plow. When the plowman had drawn the firſt furrow, he then opened another, at about ten feet diſtance from the firſt in the land; and ſeed was in the ſame manner thinly ſcattered in this alſo: after this, he returned to the firſt furrow, and drawing another cloſe to it, covered the ſeed; the ſame thing he did by the ſecond furrow: he afterwards went two bouts without any ſeed being ſown in the furrows; but the third bout ſeed, was thinly ſcattered, as before, to form the ſecond row of corn in each bed: another bout was made to cover the ſeed when the two beds were finiſhed, the middle of the interval being left unplowed.

"In this manner both my little fields were ſown, in

double rows with intervals about five or six feet wide betwixt the beds, and the rows about two feet aſunder.

" The corn came up very well, and preſerved a good wholeſome appearance all the winter.

" Early in the ſpring, that is, in the month of February, I made a careful man ſow the ſpaces betwixt the rows of corn on the heavy land with wood-aſhes, and on the light land with ſoot: theſe were both ſoon waſhed in by the rain, and the effects were ſpeedily to be ſeen in the new-aſſumed vigour of the crops, and this vigour continued till the corn was ripe.

" As ſoon as any weeds appeared, the intervals which were left unplowed at ſeed-time were turned up, and the ſpaces betwixt the rows diligently hand-hoed: this hand-hoeing was ſeveral times repeated, to keep the crop quite clear from weeds, the intervals had alſo ſeveral other ſtirrings; but this work was chiefly done with a very light plow, without an earth-board in the heavy land, and without either earth-board or coulter in the other little field.

" Every thing came very well forward; and when the wheat began to ſpindle, I had the outſides of the rows well earthed-up with a plow, and the inſides with a hand-hoe: the inſides were done firſt.

" At harveſt the fields made a noble appearance: a fine well broke earth ſtriped with rows of healthy wheat.

" The cutting this wheat was very eaſily performed, it ſtood ſo ready to the reapers hands; and when it was houſed and threſhed, it yielded me about four quarters on an acre, one with another, the firſt year, though I have ſince had ſometimes more, ſometimes a little leſs.

" My ten acres then yielded me about forty quarters; and I had occaſion for only about twenty-two to ſow my common wheat-lands: I therefore took only the firſt and prime part of this crop, getting the ſheaves very lightly threſhed; what remained made excellent bread-corn.

" I never ſaw finer ſeed-wheat than mine was this year: my heavy lands I ſowed with the ſeed produced by the light field, and my light lands with that produced by the heavy field.

" As ſoon as I had got in this ſelect crop, I got the intervals in order for ſowing with a ſecond crop, in moſt reſpects continuing the practice of the year before: I had the like ſucceſs, and might, perhaps, with equal advantage, have continued cropping the fields every year in the ſame manner: but, not to depend too much on Mr. Tull, my next crop was a full crop of barley on them, which ſucceeded well: and I ſelected two other plots of ground, of equal goodneſs, for my ſeed-corn huſbandry, as I call it.

" In this manner I have now for ſeveral years paſt managed, growing my own ſeed; and, if any thing, my crops have ſince increaſed: but I have again reduced the quantity from three to two buſhels of ſeed, for each acre of my wheat-land in common: that is, ſuch as I ſow in the ordinary way: on ſome of my rich, ſtrong land, I do not uſe above ſix pecks, and find it anſwer very well.

" I could like to extend this New Huſbandry, or this imitation at leaſt of the New Huſbandry, over all my lands that are in tillage: but in my method of practiſing, the expence would be too great: my ſowers are well paid; I have enough to do to make my plowmen go out of their ordinary way; and it coſts me a great deal hoeing: yet all this I do not grudge to procure good ſeed.

" By introducing the drill-plow and the horſe-hoe I could ſave a great deal of labour on my light lands; and I may probably ſome time or other attempt it: but, at the ſame time, I am very ſenſible, I ſhall find great difficulty in getting men that will even try to do the work with theſe inſtruments. The common labourers in huſbandry hate novelty: they purſue, without murmuring, the old beaten track; but put them out of it, and thought will become neceſſary: the fact is, they imagine it a very great hardſhip to be obliged to work and think too, and all for the ſame money.

" Without great reſolution, and ſome kind of authority, a farmer will be obliged to let them even dig a ditch their own way: innovation they like not in any ſhape, often making uſe of the expreſſion, that they are too old to learn.

" This, to a man who is very much diſpoſed to lend a helping hand towards the improvement of agriculture, is a mortifying circumſtance: there is ſcarcely any thing ſo difficult as to make an obſtinate man uſeful: if, by dint of authority, you oblige him to go out of his way, he will rather contribute to the loſs of your crop, than not to endeavour to convince you that he is in the right. I have often, to my ſorrow, felt the truth of this obſervation.

" Several reaſons, though I deal not much in them, may be aſſigned for the ſeed-wheat I raiſe in the above deſcribed manner, being ſo good.

" In the firſt place, I ſow it on land that has not taſted any dung for ſome years, but is, in its own nature, rich and good: to this practice I aſcribe a great deal of its goodneſs. In the next place, as the corn does not ſtand too thick, it enjoys all the benefit it can receive from the ſun and air: by this means it attains a perfect maturity, and is certainly improved both in bulk and quality.

" The ſlight ſpring-dreſſing I give it, of ſoot or aſhes, is of very great ſervice: it warms the roots, and brings the corn forward; it looſens the earth, and either itſelf gives nouriſhment to the plants, or, at leaſt, puts the earth in a diſpoſition to afford it.

" Not a little is to be attributed to the frequent hoeing betwixt the rows and the ſtirrings of the intervals; and I find one very particular and great advantage reſult from it, which is, that it is an excellent means of clearing my land of weeds; for they no ſooner attain a part of their growth, but they are deſtroyed long before they ſeed.

" Farmers in general think their fields cannot in the ſpring be too full of wheat-plants: the ground ſeems covered with verdure, and the blades are, as it were, crouded for want of room: when the weeds begin to get up, they ſend in a parcel of men and women with weeding-hooks, not letting a hoe come near the land to cut them up: they are ſadly afraid they ſhould not have plants enough at harveſt; whereas, if they were to meaſure and mark off a rod ſquare of land in February, and count the plants growing on it then, and afterwards count them in the beginning of Auguſt, it would almoſt always be found, that four parts in five of them had periſhed in the intermediate months, and that what remained were, by far too much crouded ſtill, and had each but few ſtalks.

" I never weed my corn of late years; for as I allow only two buſhels of ſeed, and often leſs, to an acre, the plants come up thin; and there is of courſe room for a moderate-ſized hoe, which is the inſtrument I clean my land with; and ſo far from being fearful of having my crop

crop injured by this means, I order the workmen, where the plants ſtand too cloſe, to cut them up without mercy, as they would do the moſt pernicious weeds: if there happens by any accident to be a vacant ſpot, they eaſily remove ſome plants to it, with earth about their roots, by the help of their hoe.

"By this management I, in ſome meaſure, reap the benefit of the advantages promiſed in the New Huſbandry; though I have not ſuch opportunities of ſo often giving the plants a freſh ſupply of nouriſhment, nor of earthing them up when the grain is forming in the ear; for, after the corn has put forth its ſtalks to any conſiderable length, it would not be ſo proper to ſend in the hoers: but all the loſs is the want of earthing up the plants ſo late as I could wiſh; for the weeds will, before this time, be pretty well got under, and a few of them will be able to ripen their ſeeds before harveſt, when they will of courſe be deſtroyed by turning in the ſtubble, which I always do as ſoon as poſſible; though many of my neighbours let their ſtubbles lie rough all the winter, for the ſake of feeding a few ſcore of ewes.

"Every farmer has methods peculiar to himſelf; and they are, for the moſt part, ſuch as were practiſed by their fathers, grandfathers, &c. whom they ſucceed, in the culture of their farms.

"My method, as you muſt now be ſenſible, differs from moſt of thoſe uſed by other occupiers of land; and if I cannot ſo well defend them by arguments, an experience of ſeveral years has convinced me that I ought ſtill to perſiſt in the practice of them: they have anſwered all the ends I could wiſh from them: what could I deſire more?

"I am enabled to raiſe all my own ſeed without the trouble of procuring it from a great diſtance, at a large expence, and with a deal of trouble.

"My crops are to the full as good as ever they were, and I uſe leſs ſeed by above one half: my manure goes a great deal farther than it uſed to do, becauſe I beſtow more plowing and other tillage on my land; and I am not ſo much peſtered as I formerly was with weeds, for they now very ſeldom are ſuffered to ſeed on my land.

"Of this laſt evil, I mean that of weeds, I have not, however, yet got quite rid; for ſuch of my fields as border on my neighbours lands are ſtill often infeſted; ſome of theſe ſame neighbours, I have ſeveral times mentioned, are but ſlovenly farmers, and the weeds which have winged or downy ſeeds, are conſtantly wafted by the wind from their land to mine; ſo that I, in ſome meaſure, am puniſhed for their neglects: thiſtles are this way particularly troubleſome, as the ſeeds of them will ſometimes be carried a very conſiderable way by the wind.

"I have very little more to ſay at this time, except that I never threſh the ſheaves that are to ſupply me with ſeed-corn till juſt when I want to make uſe of it. I have a notion, that the ſeed keeps better in the covering nature has given it, I mean the chaff, than it would do without it; and I am pretty certain it ſprouts ſooner in the ground, the huſk or bran of the grain being preſerved in a tenderer and more yielding ſtate, than it would be were it expoſed to the open air."

SEED-LIP, SEED-LEAP, *or* SEED-LOP, a ſeed-baſket, or the veſſel in which the ſower carries his ſeed, in order to ſow it.

SEELING, a term uſed by horſe-dealers to imply the time when a horſe begins to have white eye-brows; that is, when there grows on that part about the breadth of a farthing, a parcel of white hair, mixed with thoſe of his natural colour. This is a mark of old age, a horſe never ſeeling before he is fourteen, and always before he is ſixteen years old.

SELANDERS. *See* SALENDERS.

SEMBRADOR, an inſtrument uſed in Spain for ſowing corn. *See the article* DRILL-PLOUGH.

SEMIFISTULAR-*Flowers*, are thoſe whoſe upper part reſembles a pipe cut off obliquely.

SEMIFLOSCULOUS-*Flowers*, are thoſe whoſe petals are hollow in the lower part; but in their upper flat, and continued in the ſhape of a tongue.

SETTER, a kind of ſeton or iſſue, made by cutting a hole in the dewlap of an ox or cow, and putting into the wound a ſort of tent formed out of the root of helleboraſter; by which the ill humours vent themſelves.

To SEW, *or go* SEW, to go dry; ſpoken of a cow.

SHAKING, a diſeaſe incident to ſheep, conſiſting of a weakneſs in their hinder quarters, ſo that they cannot riſe up when they are down. No cure is yet known for it.

SHARD, a fragment of an earthen veſſel.

SHARE, *of a plough*, that part which cuts the ground, the extremity forward being covered with a ſharp-pointed iron, called the point of the ſhare; and the end of the wood behind, the tail of the ſhare. *See the article* PLOUGH.

The length of the whole ſhare from point to tail, according to Tull, ſhould be three feet nine inches; at the top of the iron it has an upright piece called the fin; and near the iron at the other end, there is an oblong ſquared hollow, called the ſocket; the uſe of which is to receive the bottom of the ſheat. Near the tail there is a thin plate of iron, well rivetted to the wood; by means of this plate the tail of the ſhare is held firmly to the hinder ſheat of the plough by a ſmall iron pin, with a ſkrew at the end, and a nut ſkrewed on it, on the inner or right ſide of the ſheat.

The point of the ſhare is that part in which it does not run up to the fin: this point is generally made of three inches and a half in length, and ſhould be flat underneath, and round at the top, and the lower part of it muſt be of hard ſteel. The edge of the fin ſhould alſo be well ſteeled, and ſhould make an acute angle with the ſhare.

The ſocket is a ſort of mortiſe; it ſhould be a foot long, and about two inches deep: the fore-end of it muſt not be perpendicular, but oblique, conformable to the end of the ſheat which enters into it. The upper edge of the fore-part muſt be always made to bear againſt the ſheat; but, if this end of the ſocket ſhould not be quite ſo oblique as the ſheat, it may be helped by paring off a ſmall part of the wood at the point.

SHAW, a wood that encompaſſes a cloſe.

SHAWLE, a ſhovel uſed in winnowing corn.

SHEARING *of ſheep*, the operation of cutting off the fleece or coat of wool with a pair of ſhears. *See the article* SHEAP.

SHEAT *of a Plough*, that part of the plough which paſſes through the beam, and is faſtened to the ſhare.

The ſheat, or as it is ſometimes called the fore-ſheat, there being another piece of timber behind it called the hinder ſheat, ſhould be ſeven inches wide, and faſtened to the beam by a retch (a piece of iron with two legs) and by a wedge driven by it into the hole of the beam. The angle contained between the ſheat and the beam of the plough ſhould be about forty-two degrees.

SHEAVES, bundles of corn bound up in the field. *See the article* HARVEST.

SHED, a ſlight temporary covering.

SHEEP, *ovis*, in zoology, a well known ſpecies of cattle, and which are kept at the leaſt expence of any to the farmer. They will thrive upon almoſt any ground, and for that reaſon are preferred by many before the larger cattle.

The beſt ſort of ſheep for fine wool are thoſe bred in Herefordſhire and Worceſterſhire, but they are ſmall and black-faced, and bear but a ſmall quantity.

Warwick, Leiceſter, Buckingham, and Northamptonſhire, breed a large boned ſheep, of the beſt ſhape, and deepeſt wool we have got. The marſhes of Lincolnſhire breed a very large kind of ſheep, but their wool is not good, unleſs the breed be mended by bringing in ſheep of other countries among them, which is a ſcheme of late very profitably followed there.

The northern counties in general breed ſheep with long, but hairy wool: and Wales breeds a ſmall hardy kind of ſheep which has the beſt-taſted fleſh, but the worſt wool of all.

The farmer ſhould always buy his ſheep from a worſe land than his own, and they ſhould be big-boned, and have a long greaſy wool, curling cloſe and well. Theſe ſheep always breed the fineſt wool, and alſo are the moſt approved of by the butcher for ſale in the market.

For the choice of ſheep to breed, the ram muſt be young, and his ſkin of the ſame colour with his wool, for the lambs will be of the ſame colour with his ſkin. He ſhould have a large long body, a broad forehead, round, and well riſing, large eyes, and ſtrait and ſhort noſtrils. The polled ſheep, that is, thoſe which have no horns, are found to be the beſt breeders. The ewe ſhould have a broad back, a large bending neck, ſmall, but ſhort; clean and nimble legs, and a thick deep wool covering her all over. To know whether they be ſound or not, the farmer ſhould examine the wool that none of it be wanting, and ſee that the gums be red, the teeth white and even, and the briſket ſkin red, the wool firm, the breath ſweet, and the feet not hot. Two years old is the beſt time for beginning to breed, and their firſt lambs ſhould not be kept too long, to weaken them by ſuckling, but be ſold as ſoon as conveniently may be. They will breed advantageouſly, till they are ſeven years old.

The farmers have a method of knowing the age of a ſheep, as a horſe's is known, by the mouth. When a ſheep is one ſhear, as they expreſs it, it has two broad teeth before; when it is two ſhear, it will have four; when three, ſix; when four, eight; after this their mouths begin to break. The difference of land makes a very great difference in the ſheep.

The fat paſtures breed ſtrait tall ſheep, and the barren hills and downs breed ſquare ſhort ones; woods and mountains breed tall and ſlender ſheep, but the beſt of all are thoſe bred upon new plowed land, and dry grounds. On the contrary, all wet and moiſt lands are bad for ſheep, eſpecially ſuch as are ſubject to be overflowed, and to have ſand and dirt left on them. The ſalt marſhes are, however, an exception to this general rule, for their ſaltneſs makes amends for their moiſture, any thing of ſalt, by reaſon of its drying quality, being of great advantage to ſheep.

As to the the time of putting the rams to the ewes, the farmer muſt conſider at what time of the ſpring his graſs will be fit to maintain them and their lambs, and whether he has turnips to do it till the graſs comes; for very often both the ewes and lambs are deſtroyed by the want of food; or, if this does not happen, if the lambs are only ſtunted in their growth by it, it is an accident that they never recover. The ewe goes wenty weeks with lamb, and according to this it is eaſy to calculate the proper time. The beſt time for them to yean is in April, unleſs the owner has very forward graſs, or turnips, or the ſheep are field ſheep, where you have not incloſures to keep them in, then it may be proper they ſhould yearn in January, that the lambs may be ſtrong by May-day, and be able to follow the dam over the fallows, and water furrows; but then the lambs that come ſo early, muſt have a great deal of care taken of them, and ſo indeed ſhould all other lambs at their firſt falling, elſe, while they are weak, the crows and magpies will peck their eyes out.

When ſheep are turned into fields of wheat or rye to feed, it muſt not be too rank firſt, for, if it be, it generally throws them into ſcowerings. Ewes that are big ſhould be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed indeed, like cows, a fortnight before-hand, to put them in heart. *Mortimer's Huſbandry.*

The feeding ſheep with turnips is one great advantage to the farmers, from the crops they raiſe of them: they ſoon fatten upon them, but there is ſome difficulty in getting them to feed on them; the old ones always refuſe them at firſt, and will ſometimes faſt three or four days, till almoſt famiſhed; but the young lambs fall to at once.

The common way, in ſome places, of turning a flock of ſheep at large into a field of turnips, is very diſadvantageous, for they will thus deſtroy as many in a fortnight, as would have kept them a whole winter. There are three other ways of feeding them on this food, all of which have their ſeveral advantages.

The firſt way is to divide the land by hurdles, and allow the ſheep to come upon ſuch a portion only at a time, as they can eat in one day, and ſo advance the hurdles farther into the ground daily, till all be eaten. This is infinitely better than the former random method, but they never eat them clean even this way, but leave the bottoms and outſides ſcooped in the ground; the people pull up theſe indeed with iron crooks, and lay them before the ſheep again, but they are commonly ſo fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but little of them, and what they do, does not nouriſh them like the freſh roots.

The ſecond way is by incloſing the ſheep in hurdles, as in the former, but in this they pull up all the turnips they ſuppoſe the ſheep can eat in one day, and daily remove the hurdles over the ground, whence they have pulled up the turnips: by this means there is no waſte, and leſs expence, for a perſon may in two hours pull up all thoſe turnips; the remaining ſhells of which would have employed three or four labourers a day to get up with their crooks out of the ground, trodden hard by the feet of the ſheap; and the worſt is, that as, in the method of pulling up firſt, the turnips are eat up clean; in this way, by the hook, they are waſted, the ſheep do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turnips

turnips are ſeen in ſuch quantities on the ſurface, that half the crop at leaſt ſeems to have been waſted.

The third manner is to pull up the turnips, and remove them in a cart or waggon to ſome other place, ſpreading them on a freſh place every day; by this means the ſheep will eat them up clean, both roots and leaves. The great advantage of this method is, when there is a land not far off which wants dung more than that where the turnips grow, which perhaps is alſo too wet for the ſheep in winter, and then the turnips will, by the too great moiſture and dirt of the ſoil, ſometimes ſpoil the ſheep, and give them the rot. Yet ſuch ground will often bring forth more and larger turnips than dry land; and when they are carried off, and eaten by the ſheep on ploughed land in dry weather, and on green ſward in wet weather, the ſheep will ſucceed much the better; and the moiſt ſoil, where the turnips grow, not being trodden by the ſheep, will be much fitter for a crop of corn, than if they had been fed with the turnips on it. The expence of hurdles, and the trouble of moving them is ſaved in this caſe, and this will counterbalance at leaſt the expence of pulling the turnips, and carrying them to the places where they are to be eaten. They muſt always be carried off for oxen. *Tull's Horſe-hoeing Huſbandry.*

"It can hardly be doubted, ſays, M. de Buffon, but that thoſe animals which are at preſent tame and domeſtic, were formerly wild. Yet the weakneſs and ſtupidity of the ſheep being conſidered, and likewiſe that this defenceleſs animal cannot ſave itſelf by flight; that all carnivorous animals are his enemies, ſingling it out in preference to others, and devouring it for the fineneſs of its fleſh: at the ſame time we muſt remember that this ſpecies is not very prolific, and that each individual is but ſhort-lived: when theſe particulars are conſidered, we ſhould be inclined to think, that from the beginning of things, the ſheep has been committed to the care of man: that his protection is neceſſary to its ſubſiſtance, and his care to its multiplying; nor are any deſarts known to afford wild ſheep; but in all places where man does not govern, the lion, the tyger, and the wolf, reign by violence and cruelty; theſe voracious animals live longer, and multiply much faſter than the ſheep: and were we even now to forſake the numerous flocks fed in the paſtures, and on the hills, they would ſoon be deſtroyed before our eyes, and the whole ſpecies extirpated by the number and voracious appetites of carnivorous animals.

"Thus it appears that this ſpecies is indebted to our aſſiſtance and care for its continuance; for it could not ſubſiſt of itſelf. The ſheep is abſolutely without defence or reſource; the weapons of the ram are but weak; his courage nothing more than a petulance, troubleſome to others, uſeleſs to himſelf, and deſtroyed by caſtration. The weathers are ſtill more timorous than the ewes. It is from fear that they ſo often aſſemble in flocks; the leaſt uncommon noiſe cauſes them to leap over each other, or gather cloſe together; while this fear is attended with the groſſeſt ſtupidity: they have not ſenſe to avoid danger; they even appear not to feel their diſagreeable ſituation; they ſtray wherever they happen to be, whether it rain or ſnow; and ſuch is their obſtinacy, that in order to make them change their place, or follow any road, they muſt have a leader, trained to walk before them, whoſe motions they readily follow ſtep by ſtep. This leader himſelf would ſtir no more than the reſt of the flock, were he not driven by the ſhepherd, or hunted by the guardian dog, which is taught to protect and defend them; to guide, ſeparate, gather them together, and direct them in their motions.

"Sheep, therefore, of all quadruped animals are the moſt ſtupid, and have the leaſt inſtinct and contrivance. The goats, which in ſo many reſpects reſemble them, have much more ſagacity; they ſtand in need of no guide, they ſhun dangers; new objects ſoon become familiar to them; whereas the ſtupid ſheep neither ſhuns nor approaches: though under the greateſt want of aſſiſtance, they do not approach man ſo freely as the goat; and what in animals ſeems the loweſt degree either of fear or inſenſibility, they ſee their lambs taken away without anger, without reſiſtance, and without expreſſing their grief by any cry different from their common bleating.

"But this animal, in itſelf ſo deſpicable, ſo deſtitute of ſentiment and internal qualities, is to man the moſt valuable; its utility the moſt immediate and extenſive: it alone ſatisfies wants of the greateſt neceſſity; it furniſhes both food and apparel, beſides the advantages ariſing from the ſuet, mik, ſkin, intrails, bones, and dung of this creature, to which nature ſeems to have given nothing as its property; all is to be delivered up to man.

"Love, the moſt general and active ſentiment, is alone able to impart ſome vivacity to the ram: he becomes wanton, fights, ruſhes againſt the other rains, and ſometimes even attacks his ſhepherd; but the ewe, when in heat, ſeems not at all the more affected, or the more animated; her inſtinct reaches no farther than not to refuſe the ram's aproaches; to chuſe her food, and know her lamb. The inſtinct of this animal is the ſurer, as it is more mechanical; and, if I may be allowed the expreſſion, the more innate. A young lamb will, amidſt a numerous flock, find its dam and ſeize the dug, without ever being miſtaken. Sheep are alſo ſaid to be impreſſed by modulated ſounds, to feed more aſſiduouſly, to be in better health, and to fatten ſooner by the ſound of a pipe; and that they are evidently ſenſible of the charms of muſic. But it is alſo ſaid, and I believe with more truth, that muſic rather ſerves to amuſe the ſhepherd's tedious hours, and that to this ſupine and ſolitary life the origin of that art is owing.

"Theſe animals, whoſe inſtinct is ſo ſimple, are alſo of a very weak conſtitution; they cannot bear walking any length of time; travelling exhauſts them; running ſoon puts them out of breath; the ſcorching rays of the ſun hurt them eqally with the rain and ſnow. Their diſeaſes are many, and moſt of them contagious. The ſuperabundance of their fat often proves fatal to them, and always hinders their fruitfulneſs; they yean with difficulty; they frequently caſt their lambs, and require more care than any other domeſtic animal.

"When a ewe is near yeaning, ſhe muſt be ſeparated from the flock, and watched, in order to be aſſiſted; the lamb often preſents itſelf a-thwart, or with its feet firſt; and in this caſe, without aſſiſtance, the ewe's life would be in danger. After yeaning, the lamb is raiſed on his feet; at the ſame time all the milk in the ewe's udder is milked out, it being vitiated, and very noxious to the lamb, which is kept from ſucking till the udder is filled with freſh milk: the lamb is kept warm, and for three or four days ſhut up with the ewe, that it may learn to know her, during which time the ewe is fed with good hay, barley-meal, or bran mixed with a little ſalt; and water, whoſe chill is taken off, and mixed with a little quantity

of

of flour, bean-meal, or ground millet, given her to drink. At the end of four or five days ſhe may be gradually fed like the reſt, and ſent with the flock, taking care that ſhe be not driven too far, leſt her milk be heated. Some time after, when the ſucking lamb ſhall have gathered ſtrength, and begins to play, no farther care is requiſite; it may be left to follow its dam to the paſtures.

"All the lambs of a weekly appearance are generally diſpoſed of to the butcher; thoſe intended to be kept being the largeſt, moſt vigorous, and having the thickeſt fleece. Lambs of the firſt yeaning are never ſo good as the following. To bring up lambs yeaned in the months of October, November, December, January, and February, they muſt be kept in the houſe during the winter, going out only in the morning and evening to ſuck; but in the beginning of April they may be turned into the open fields. Some time before this a little graſs is daily given them, in order to habituate them by degrees to this new food. They may be weaned at the end of one month; but it is better to delay it for ſix weeks or two months. White lambs, without ſpots, are always preferred to the black or mottled; white wool being more valuable than the black or mixed.

"The proper age for caſtration is at the end of five or ſix months, or even a little later in ſpring or autumn, when the weather is mild. This operation is performed by two different methods; the moſt common is by inciſion, when the teſticles, which are eaſily ſeparated, are drawn out through the wound: the other is performed without inciſion, by tying a ſtring very tight round the ſcrotum above the teſticles: for this compreſſion deſtroys the veſſels which ſupplies them with blood and juices. The lamb, on caſtration, becomes ſickiſh and dull, ſo that it would not be improper to give him, for two or three days, a little bran mixed with a ſmall quantity of ſalt, to prevent a loſs of appetite, which this operation often cauſes.

"At the end of a year, rams, ſheep, and weathers loſe the two fore-teeth of the lower jaw; and they are known to want the inciſive teeth in the upper jaw. At eighteen months the two teeth joining to the former, alſo fall out; and at three years, being all re-placed, they are even and pretty white. But as the creature advances in age they become looſe, blunt, and afterwards black. The age of the ram is alſo known by his horns, which ſhew themſelves in the very firſt year, and, often at the birth, and continue to grow a ring annually to the very period of life. Though ſheep are often without horns, yet they have bony prominencies in the ſame places of the head, where the horns of rams appear. Some ſheep however have two, and others four horns, five or ſix inches in length, but leſs twiſted than thoſe of the ram; when there are four, the two outward are ſhorter than the others.

"The ram is capable of generating at eighteen months, and a ewe may yean at the end of a year; but it is better to delay it till the ewe be two, and the ram three years old. The produce of theſe animals, if too early, and even the firſt, is always weak, and of a bad conſtitution. One ram will be ſufficient for twenty-five or thirty ewes; but he ſhould be remarkable for ſtrength and comelineſs. He muſt alſo have horns; for ſome have none, and ſuch, in theſe climates, are very indifferent. In a good and comely ram, the head muſt be large and thick, the forehead broad, the eyes large and black, the noſe ſhort, the neck thick, the body long and raiſed, the back and rump broad, the teſticles large, and the tail long. The beſt are white, with a large quantity of wool on the belly, tail, head and ears, down to the eyes. The beſt ſheep for propagation are thoſe which have moſt wool, and that cloſe, long, ſilky, and white; eſpecially if at the ſame time they have a large body, a thick neck, and a light method of walking. And it has been already obſerved, that thoſe which were rather lean than fat, bring forth more eaſily than others.

"The ſeaſon of the ewe's heat is from the beginning of November to the end of April; but they may be brought to conceive in any ſeaſon, by giving them provocative foods, as ſalt water, and bread of hemp-ſeed. Each ewe is covered three or four times, and then ſeparated from the ram, which always prefers the older ſheep, and neglects the younger. In the ſeaſon of copulation they ſhould not be expoſed to the rain or bad weather, wet hindering their retention; and a clap of thunder often produces abortion. A day or two after being covered, they are put again to their common diet, without having any more ſalt water; the continual uſe of which, as well as that of hemp-ſeed bread, and other hot aliments, would infallibly cauſe abortion. They go five months, and yean at the beginning of the ſixth; they ſeldom bring two lambs. In hot climates they yean twice a year: but in France, and the colder countries, only once. Some have the ram given to them about the end of July or the beginning of Auguſt, in order to have lambs in the month of January; but the ram is given to a much greater number in the months of September, October, and November; and lambs are in great plenty in February, March, and April. They are alſo to be had in the months of May, June, July, Auguſt, and September, there being no ſcarcity of them but in October, November and December. The ewe yields, during ſeven or eight months, plenty of milk, which is a good food for children and peaſants. It alſo makes good cheeſe, eſpecially if mixed with that of cows. The time for milking ewes is immediately on their going out to paſture, or on their return; twice a day in ſummer, and once in winter.

"Ewes fatten very faſt during their pregnancy, as they then eat more than at other times. As they often hurt themſelves, and frequently miſcarry, ſo they ſometimes become barren; and it is not very extraordinary for them to bring forth monſtrous productions. However, when properly tended, they are capable of yeaning during their whole life; that is, to the age of ten or twelve years; but generally, when they are turned of ſeven or eight, they break, and become ſickly. A ram lives to twelve or fourteen years; but after eight is no longer fit for propagation: he ſhould then be knit and fattened with the old ſheep. The fleſh of the ram, though knit and fattened, is but of a bad taſte; that of the old ewe flabby and inſipid; whereas that of the weather is the moſt ſucculent, and the beſt of all common meats.

"To form a flock, from which a reaſonable profit may be expected, ſheep and weathers muſt be purchaſed, of about eighteen months, or two years old; and one ſhepherd, if careful, and aſſiſted by a good dog, may take care of a hundred. In leading them out to paſture he ſhould go before them, and accuſtom them to know his voice, to follow him without ſtopping, or ſtraying among the corn, woods, and fallow lands, where they would do damage. The places that beſt agree with them are downs, and ſmall eminencies; low, wet, and marſhy grounds ſhould be avoided.

"During

" During the winter, they are fed at home with bran, turnips, hay, ſtraw, lucern, ſaintfoin, the leaves of elm, aſh, &c. They are, however, led out every day, unleſs the weather be very bad; tho' this is rather to walk than feed them; and in this inclement ſeaſon, it is always near ten in the morning before they are led out; and after ſtaying four or five hours, they are watered, and brought back about three in the afternoon; whereas in ſpring and autumn, they are led to the field as ſoon as the ſun has diſperſed the froſt or humidity on the graſs, and continue there till ſun-ſet. It is alſo ſufficient for them in theſe ſeaſons, to drink once a day, juſt before they are brought back to the ſheep-houſe, where they muſt always find fodder, though in leſs quantity than in winter. It is only in ſummer that they are to live entirely on the paſtures, whither they are led twice a day, and alſo made to drink twice. They are led out very early in the morning to feed as ſoon as the dew is down, where they continue four or five hours; after which, and being had to the water, they are brought back to the fold, ſheep-houſe, or ſome other ſhady place: about three or four o'clock, when the extreme heat begins to abate, they are a ſecond time led to the paſture, where they continue till the evening; and were it not for the fear of wolves, they ſhould paſs the night in the open air, as they do in England, which would render them more vigorous, clean, and healthy. As too great a heat is remarkably troubleſome, and the violence of the ſun-beams diſorders their heads, and throws them into vertigo's, it is proper to make choice of places ſhaded from the ſun, and in the morning to lead them on eminencies expoſed to the eaſt, and in the afternoon on thoſe that are expoſed to the weſt, that when they are feeding, their heads may be in the ſhadow of their body. Laſtly, in order to ſave their wool, they muſt not be led through any buſhy places.

" In dry and high grounds, eſpecially if the herbage abound in wild thyme, and other odoriferous plants, the mutton is of a much finer quality than that which is fed in moiſt vallies and low plains; unleſs theſe plains be ſandy and near the ſea, the herbage then being ſprinkled with ſalt; and the ſheep are no-where ſo good as on theſe ſalt plains. The ewes alſo fed in them, yield more milk, and of a better taſte. Theſe animals are remarkably fond of ſalt, and nothing is more healthful when given in moderation; and in ſome places it is cuſtomary to put into the ſheep-houſe a bag of ſalt, or a ſaline ſtone, which they all greedily lick one after another.

" Every year the flock ſhould be examined, in order to find out ſuch as begin to grow old, and are intended for fattening; for as they require a different management from the others, ſo they ſhould alſo be formed into a ſeparate flock. They ſhould be led abroad in ſummer before ſun-riſing, in order to feed on the graſs while moiſtened with the dew. Nothing forwards the fattening of weathers more than a great quantity of moiſture; and nothing more obſtructs it than the heat of the ſun; ſo that about eight or nine in the morning, before the great heat begins, they ſhould be brought back, and ſalt given them to excite thirſt. About four in the afternoon they ſhould be led a ſecond time into cool and moiſt places; and after two or three months of theſe little cares, they will have all the appearance of being full of fleſh: indeed they are generally fattened as much as they can be; but this fat proceeding only from the great quantity of water they have drank, may be ſaid to be no more than an œdema, or bloated humour, which would in a ſhort time turn to the rot, and can be prevented only by killing them while in this ſtate of fatneſs. Even their fleſh, far from being firm and juicy, is extremely inſipid and flabby: in order, therefore to make good fleſh, beſides letting them feed on the dew, and giving them a great deal of water, they ſhould have, at the ſame time, more ſucculent food than graſs. They may be fattened in every ſeaſon, by only keeping them a-part in a ſheep-houſe, and feeding them with the meal of barley, oats, wheat, beans, &c. mixed with ſalt, for making them drink more copiouſly. But in whatever manner, and in whatever ſeaſon they are fattened, they muſt be immediately diſpoſed of; for they cannot be fattened twice, and they will die by diſeaſes of the liver.

" Worms are often found in the livers of animals; and a deſcription of thoſe found in the liver of ſheep and oxen, may be ſeen in the Journal de Scavans, for the year 1668, and Ephemerides of Germany, tom. v. 1675, 1676. Theſe worms were thought to be peculiar to ruminant animals; but M. Daubenton has found the very ſame in the liver of the aſs; and it is probable the like may be found in the liver of other animals: but it is alſo affirmed, that moths have been found in the liver of ſheep." M. Rouille, ſecretary of ſtate for foreign affairs, was ſo kind as to communicate to me a letter to him, from a doctor of phyſic at Montiers, in the duchy of Taranteiſie in Savoy, from whence I have made the following extract. " It has for a long time been obſerved, that the ſheep of our Alps, which are the beſt in all Europe, ſometimes fall away ſurprizingly. Their eyes become white, ſunk, and blared; their blood ſerous, with ſcarce any redneſs to be ſeen in it; their tongue dry and ſhrivelled; their noſe ſtuffed with a yellow, viſcid and putrid mucus; an extreme debility, though they eat a great deal; and, in fine, the whole animal ſyſtem viſibly decaying. After ſeveral cloſe enquiries, theſe animals were found to have in their liver white papilios, with proper wings; their heads of a ſemi-oval form, bilious, and of the bigneſs of thoſe belonging to the ſilk-worm. I have been convinced of the reality of this fact, by ſqueezing above ſeventy out of the two lobes; and, at the ſame time, all the convex part of the liver became lacerated. They have been found in the veins only, without a ſingle inſtance of their being in the arteries. In the cyſtic duct ſmall ones have been found, together with ſmall maggots. The vena porta, and the capſula of Douglas, which are viſible there as in man, yielded to the ſofteſt touch. The lungs and other viſcera were ſound." It were to be wiſhed that the doctor had given us a more circumſtantial deſcription of theſe papilios; that theſe animals which he ſaw may not be ſuſpected to be no other than the common worms found in the liver of a ſheep, which are very flat and broad, and of ſo ſingular a figure, that they would rather be taken for leaves than worms.

" Every year the whole flock, weathers, ewes and lambs, are ſheared. In hot countries, where the creature may without danger be laid bare, the wool is not ſheared, but plucked off; and often they yield two fleeces in a year. In France, and the colder climates, it is cut only once a year with large ſhears, ſtill leaving the ſheep part of their fleece, as ſome defence againſt the ſeverity of the climate. The ſeaſon for this operation is in the month of May, after thoroughly waſhing them, that the wool may be as clean as poſſible. In the month of April it is too cold; and if delayed till June or July, the wool would not grow ſufficiently during the remainder of the ſummer, to ſecure them

from

from the winter's cold. The weathers have generally more wool than the ewes, and it is alſo better. That of the neck, and the top of the back is the prime; that of the thighs, tail, belly, throat &c. is not ſo good, and worſt is that taken from dead beaſts, or ſuch as are ſick. White wool is alſo preferred to the grey, brown, and black, as it may be dyed of any colour. Strait wool is better than curled; and it is even ſaid that the weathers whoſe wool is too much curled, are not in ſo good a ſtate of health as the others. A conſiderable advantage may alſo be drawn from ſheep by folding them; that is, by leaving them for a proper time on lands intended for improvement. In order to this, the ground muſt be incloſed, and the flock ſhut up in it every night during the ſummer. By this means the dung, urnine, and heat of the body of theſe creatures, will in a ſhort time bring the ground into heart, whether exhauſted, or naturally cold and barren. A hundred ſheep will in one ſummer meliorate eight acres of ground, which will continue its fertility ſix years.

"We are told by the ancients, that all ruminant animals have ſuet, though this is ſtrictly true only of the goat and ſheep; and that of the ſheep is in greater quantity, whiter, drier, finer, and of a better quality than any other. Fat differs from ſuet, as continuing always ſoft; whereas ſuet hardens as it grows cold. It is chiefly about the kidneys that the ſuet is found; and the left has always more of it than the right. There is alſo a great deal of it in the caul, and about the inteſtines; but this ſuet is far leſs firm and good than that of the kidneys, the tail, and other parts of the body. Weathers have no other fat than ſuet; and ſo predominant is this fat in their conſtitution, that all the extremities of their fleſh are covered with it. Their very blood is not without it; and the ſeminal lymph is ſo ſaturated with it, as to appear of a different conſiſtence from that of other animals. The lymph of the human ſpecies, that of the dog, the horſe, the aſs, and probably of all animals without ſuet, liquifies by cold, rarifies in the air, and becomes the more fluid from the time it was ejected from the animal's body. On the contrary, the ſeminal liquor of the ram, as well as that of the goat, and probably other animals that have ſuet, inſtead of rarifying in the air, hardens like ſuet, and, with its heat, loſes all its liquidity. This difference I have perceived by microſcopical obſervations on theſe ſeminal lymphs. That of the ram coagulates in a few ſeconds after its leaving the body, and to perceive the living organical moleculæ, of which it contains a prodigious quantity, the object plate muſt be heated, in order to preſerve it in a ſtate of fluidity.

"The taſte of the fleſh, the fineneſs of the wool, the quantity of the ſuet, and even the ſize of theſe animals, differs very greatly in different countries. In France they chiefly abound in the duchy of Berry; thoſe in the neighbourhood of Beauvais, and ſome other parts of Normandy are the largeſt, and the fulleſt of ſuet. In Burgundy they are very good; but the beſt are thoſe that feed on the ſandy coaſts of our maritime provinces. The wools of Italy, Spain, and England, are finer than thoſe of France. In Poitou, Provence, the neighbourhood of Bayonne, and ſome other parts of France, there are ſheep which ſeem to be of a foreign breed; they are ſtronger, larger, and have a great deal more wool than thoſe of the common breed. Theſe ſheep are alſo more prolific than the other, it being nothing extraordinary with them to have two lambs at a time, and yean twice a year. The rams of this breed, engendering with the common ewes, produce an intermediate breed, partaking of the two from whom it proceeds. In Italy and Spain, the number and variety in the breeds of ſheep is ſtill greater; but all muſt be conſidered as forming one and the ſame ſpecies with our ſheep; tho' this ſo numerous and diverſified ſpecies hardly extends beyond Europe. Thoſe long and broad tailed creatures ſo common in Africa and Aſia, and by travellers called Barbary ſheep, ſeem to be of a ſpecies different from ours, as well as the American, Vigonia, and Llama.

"White wool being much more eſteemed than black, ſpotted or black lambs are almoſt every where ſold to the butcher; though in ſome places the far greater part of the ſheep are black; and for black lambs to be produced by a white ram and ewe, is a phænomenon common in every country. In France there are only white, brown, black, and ſpotted ſheep; Spain has dun ſheep; in Scotland there are yellow; but all theſe differences and varieties in the colour are no more fortuitous than the differences and varieties of the breeds, which are, however, wholly owing to the effects of the food, and the difference of the climate." *Buffon's Hiſtoire Naturelle, tom.* v.

The reader is indebted to the ingenious Mr. Irwin for the following obſervations relating to the management of ſheep in Ireland.

"Of all the quadrupeds, ſays he, the ſheep perhaps is the animal beſt adapted by Providence to pay the rent. It requires great attention to it; but, at the ſame time, little bodily trouble. The chief care ſhould conſiſt in their cantonment for food, in which our Iriſh farmers are extremely negligent (I mean thoſe of them that have abilities to be otherwiſe); for they ſtation them promiſcuouſly over the land, encloſing only the fattening grounds, which is done but badly, and other cattle ſuffered to mix with them; whereas ſheep, in their rearing and fattening ſtate, ſhould be by no means ſuffered to perambulate a variety of paſture. For this reaſon.

"Moſt cloſes, or encloſed fields, have ſome herbage, beſides the common graſs, predominant in them; and where ſheep are ſuffered to run over too many of theſe at once, the different mixtures in ſuch extenſive paſtures have, I am convinced, from repeated experimental obſervations, very unfavourable effects on this tender and delicate animal, both as to rearing and fattening, or as to bone and growth.

"It actually gives, or inclines them to a ſcower (and other diſorders well known to the ſhepherds) oftentimes not leſs prejudicial than that which they never fail getting in low ſwampy grounds, which always proves mortal to ſheep that are ſuffered to remain ever ſo ſhort a time in ſuch places; for though the noxious inſane effects of ſuch paſture may not immediately appear, or operate on them, it never fails bringing on the rot in the end, which manifeſts itſelf by the ſcower, and other unhealthy ſymptoms.

"A gentleman in my neighbourhood, who occupies ſeveral thouſand acres of deep, rich ſoil, ſuffered a conſiderable loſs of ſheep, particularly ewes, in the ſpring of 1759. (I think it was) and that ſeaſon was far from being inclement, eſpecially wet, which is the moſt unfavourable weather to that kind of ſtock.

"I made cloſe enquiry into the cauſes of this uncommon mortality, for ſuch it appeared to me at that time.

"The

" The common reaſons for this deſtructive peſtilence were indeed given: but from ſome obſervations I made from appearances, I did not judge them ſatisfactory.

" It ſeemed to me that a two extenſive run of over fertile, luxuriant ſoil, little or no ſhelter, negligence in folding, and other care not difficult to be taken, but abſolutely neceſſary to the well being of this delicate animal, had brought on a deadly and general rot.

" Many were with difficulty ſaved, only to languiſh away, in all probability, the ſucceeding winter; for though a ſheep, the firſt time it is tainted with the rot, whether in winter or ſummer, may for that ſeaſon, with great care and difficulty, be preſerved, it nevertheleſs ſeldom happens that any amelioration of paſture will make it a long liver; for when it is once touched with this diſorder, a cure may (as in many human chronical diſeaſes) be patched up; but it will never get thoroughly clear of it. Hence the generality of our farmers, though they may think otherwiſe from their practice, appear to me to be in great error in this reſpect.

" But their ſtock is commonly too large, and they are continually buying in, or ſelling out; ſo that by not keeping them for any length of time, they have not proper opportunities to explore rightly the effects of the cauſes we are now inveſtigating.

" The largeneſs of their ſtock, I ſay, prevents them from looking minutely into theſe neceſſary matters, which is not in general the caſe in England. Beſides, from the great numbers they oftentimes poſſeſs, they are ſo accuſtomed to loſſes in this way, and ſo little attendant to phyſical cauſes, that they are things of courſe with them; neglects I call them, that a little attention would eaſily remedy, were the flocks never ſo large: and in this reſpect indeed it muſt be admitted, cuſtom erroneouſly commits too many to the care of one ſhepherd in a country not yet thoroughly improved.

" Through the lazineſs or inattention of the herd (for careleſs they almoſt all are) many caſualties they pretend ariſe from the unimproved ſtate of the farm, and eaſily impoſe them as ſuch on their employers, whereas they ſolely proceed from their own neglect.

" To remove ſheep often is an excellent temporary preventative againſt the rot, and moſt other diſorders incident to them; but to fold them dry a-nights is ſtill more infallible; that is, to keep them from rain; but the largeneſs of the flocks in Ireland, moſt people imagine, is an abſolute bar againſt this ſalutary expedient.

" This is an ill-founded ſurmize. If they would divide their ſtock into ſmaller proportion, that is, to limit their ſheep walks to one or two hundred acres at moſt, under the care of one man; to allow to theſe proportions (the land being, we will ſuppoſe, of no more than a middling good ſort) three ſheep *per* acre in ſummer, and one and a half in winter, in the rearing or breeding way; and to erect on every ſuch farm proportionable ſhelter-houſes to a ſouth, or ſouth-by-eaſt aſpect, (but never to the north or weſt, the winds blowing, eſpecially from the latter point too long and cold) there would not be one third of the annual dearth of ſheep there is; and in this computation I fancy the proportion is exceeded.

" Thoſe who hold very extenſive tracts, may ſay this ſimple expedient is not practicable; but it certainly is, both to the conſiderable and inconſiderable farmer, even in parts where timber is not eaſily had, which ſeems to be the chief difficulty. Suppoſe now (to give a very feaſible hint) a houſe made of turf (if no ſtone or brick could be conveniently had) one hundred feet long, about fourteen wide, and the wall about five feet high, with four large doors or openings to the aſpects before-mentioned; ſlight and cheap timber girthing, eaſily carried from afar, would do for this buſineſs as well as the beſt; the thatch whether ſtraw out of the barn, or ſtubble, which laſt is far the beſt, we know, is of trifling value in thoſe parts, and ought to be well ſowed on with ropes, which makes it effectually reſiſt ſtormy weather; and the erecting the wall of turf, or, which is much better, with clay-mortar, well mixed with ſtraw-rubbiſh, we alſo know, cannot coſt much, where labour is but from a groat to ſix-pence a day.

" In ſhort, I could erect one of theſe houſes in this manner on every hundred acres, which is the quantity of land that ought to be allowed to each, for fifteen pounds, Iriſh money, or, at moſt, twenty. The land, ſpoiled by digging off the ſods, would be ſoon reſtored by the treading of the ſheep. The hay-yard, of courſe, to be adjoining this houſe.

" All the objection I think can be made is, the not being able to move theſe houſes, thereby to ameliorate different ſpots of the farm, as they do in Switzerland their wooden houſes that run on wheels.

" Conveniencies in countries are different: in Switzerland there is plenty of wood; in many parts of Ireland the length and difficulty of carriage renders a ſufficiency of it for this purpoſe impoſſible to be had: beſides, moving houſes, for aught I know, may do well in Switzerland, or in England; but ſuch as I mention would anſwer extremely well in Ireland.

" In this way I am ſenſible the winter-mucking would be almoſt always on one ſpot; but it would make much dung, which might be removed to great advantage; and if it had not, it is not evident that it would be much more beneficial to loſe the night-mucking, during the three or four moſt inclement months of the year, than treble the worth of it of one's ſtock? Moreover, I am not clear, but the dung being preſerved from the froſt would go farther than if ſcattered by the ſheep about the land in hard weather: and, though it is much the cuſtom to turn out dung in that ſeaſon, I am certain, (and many phyſical cauſes will demonſtrate it) the ſooner afterwards it is mixed with the land, the more of its virtue it will retain.

" But before I quit the article of ſheep: as I ſaid before, countries and circumſtances differ; for though I do not approve of extenſive unincloſed paſtures in Ireland, it ſeems in Spain they do well enough; the flocks there are ſmall, as in France; but they have a right of commonage in that country, perhaps not in any other civilized one that we know of.

" There it is a conſtant practice with the ſhepherds, ſoon after ſhearing time, to ſet out with their flocks, generally conſiſting of about an hundred each, and to paſs from one province to another, feeding them promiſcuouſly both on ley and corn lands, the meadows, and ſome other particular encloſed lands, as parks belonging to the nobility, and clergy eſpecially, only excepted.

" Theſe itinerant ſhepherds often travel three or four hundred miles from their habitation with their ſmall flock: they ſometimes take part of their family, a good deal of proviſions, a tent, and ſome well-trained dogs, and are never ſtopped if they keep the ſheep on the open lands, and often do not return home till after lambing-time.

" They generally have one third, or half the profit of

the flock for their hire." *Muſeum Ruſticum, vol.* I. *page* 449.

"I think, ſays another writer in the Muſeum Ruſticum, that early ſhearing ſhould be preferred on many accounts: ſome defer this work till at or after Midſummer; but this ſhould be avoided, as very bad conſequences often enſue. By this late ſhearing, the maggot has an opportunity of breeding in their ſkins; and this frets them in ſuch a manner, that they often pine away, and loſe all their fleſh.

"This is eaſily prevented by early ſhearing; and, therefore if the weather be any thing tolerable, I generally do this work about the middle of May, and ſometimes the beginning of that month: by this method the new growth of the wool has time to get a-head, ſo as to ſecure the ſheep from the attack of the fly. It is true, that at this time of the year the weather is often cold, and chilling rains fall, which might endanger my new-ſhorn ſheep, was no farther care taken of them: but this danger I always guard againſt, by waſhing my ſheep, after ſhearing, with ſalt-water taken from the Medway: this is of great ſervice in killing any vermin that may harbour cloſe to their ſkins; and, beſides this advantage, the penetrating quality of the ſalt ſo warms this animal's maſs of blood, that it is a great means of preſerving it from many diſorders to which it is fatally ſubject; ſuch as the gripes, ſcab, red-water, rot, &c. &c. &c. This, I ſay, has been my practice ever ſince I have lived in Kent; but before that time, when I was not within diſtance of the ſea or Medway, to get ſalt-water from thence, I always made a brine of a proper ſtrength with common ſalt and ſoft water, and applied it to the ſame uſe with equal benefit, though it coſt me, to be ſure, ſomewhat more. When my ſheep have ſores, either by the bite of flies, or by ſcratching, &c. I find the beſt remedy to be that which is commonly in uſe, viz. a little tar applied to the wound: many, if you aſk their advice, will, by way of ſhewing their judgment, preſcribe to you complicated mixtures, which have no other merit but being more expenſive: but be aſſured, the more ſimple the remedy, the ſpeedier the cure.

"Many farmers ſuffer great loſſes by buying ſheep that are rotten; for which reaſon, every prudent man ſhould, when he buys a lot of ſheep, agree with the ſeller, that he ſhall warrant them ſound for a month at leaſt: this would prevent many heavy loſſes, and be a means of guarding honeſt men from being impoſed on. If ſheep are the leaſt inclinable to the rot, the beſt remedy is to drive them directly into a dry upland paſture.

"Though I ſhear my ſheep ſooner than moſt of my neighbours, I ſhould alſo have obſerved, that I always ſhear my fat weathers firſt, as they are beſt able to bear the cold; and I reſerve my poor ſheep till laſt, as the cold and chilling rains pinch them more than the others." *Muſeum Ruſticum, vol.* I. *page* 210.

I never uſed, ſays Mr. Liſle, "to ſhear till the Monday before Midſummer day; but I now (anno 1714) find I was in an error in ſo doing; and that, as my keeping is very good, by which means the wool grows the larger, and heats the ſheep the more, and their fleſhineſs being ſuch as to bear the cold the earlier in parting with their fleeces, I ought to begin to ſhear the firſt week in June; and the ſheep would not only thrive much the better, when the load of their wool was gone, but their new wool would alſo have more time to grow againſt Wayhill fair, which would make the ſheep look more burley." *Liſle's Huſbandry, vol.* II. *p.* 275.

We cannot but in general approve of the early ſhearing of ſheep, beginning with the fatteſt; but no certain day can, with reaſon, be fixed for doing this work; for our ſeaſons differ ſo much in various years, that next year, in the beginning of May, the weather may be ſo warm as to be very proper for the work; and in the following year, the middle of the ſame month may, on account of the cold, be too ſoon to begin. The beſt regulator for this work, as well as many others, would be the ſtate of vegetation, from repeated obſervation of ſome particular tree or plant, on a particular ſoil and expoſure; for to bring plants to a certain ſtate, requires always a certain degree of heat, and this is ſooner or later, according to the ſeaſon. Every work of huſbandry, in ſpring at leaſt, might be regulated in the ſame manner, and that to great advantage, for nature is an unerring guide.

The ſheep of the Ardennes, a foreſt in Lower Germany, are every where celebrated for the exquiſite delicacy of their fleſh; and, from a particular method of ſhearing them, their wool alſo is in no leſs eſteem.

"Amidſt all the accidents and diſtempers to which ſheep are liable, ſeldom any of them are known to die, certain innocent remedies ſoon reſtoring them. I have obſerved, every where elſe there is a fixed ſeaſon for ſhearing ſheep; and accordingly I have ſeen not a few, after being ſhorn, ſhivering with the ſharpneſs of the air; whereas, in the Ardennes, if the month of April or May be too hot or too cold, the ſhearing is delayed; and it is not often they ſet about it before the middle of ſummer. If, when bared, they are found to have received any wound in the ſhearing, it is rubbed over with a liquid pitch, and all the reſt of the body well waſhed with wine or oil.

"In ſome part of the Ardennes, the wine is mixed with oil-lees, or an ointment is made of wine, oil, and virgin-wax; and this precaution is ſaid not only to thicken their wool, but alſo preſerves them from ſores and the ſcab. They are never ſheared in the morning, it being a proverb in the country, that wool is to be ſheared, as fruits deſigned for keeping are to be gathered, when the dew and coolneſs have been exhaled by the heat of the ſun. If ſheep are ſheared when ſweating, the wool, by imbibing the ſweat, becomes the ſofter and better coloured.

Sheep are ſubject to a kind of diſtemper, which, within two or three weeks, frequently ſweeps away a whole flock; but, to prevent ſuch a fatality, the Ardennes ſheep, at the beginning of the ſpring, have a certain potion given them.

"The flock is firſt carefully examined, and the ailing ſheep ſeparated from the ſound; an excellent method! yet is the Ardennes the only place where I ever ſaw it practiſed: after this, the juice of wild ſage and hore-hound, well cleanſed, is mixed in their drink, and this continued for a fortnight ſucceſſively. In autumn this medicament is repeated; and thoſe which are ſick likewiſe go through the ſame courſe during a fortnight, and generally with a very happy effect.

"Upon being ſeized with the ſcab, which the negligence of the ſhepherds does but too often occaſion, an ointment is prepared for them of the juice of any kind of ſage, mixed up to a conſiſtency with pulveriſed ceruſs and freſh butter: with this the ſheep are rubbed, and, three days after, waſhed with the urine of a ſhe-aſs, which cures them.

"If the exceſſive heats have ſo affected them, that they grow ſickly and faint, and even to a total loſs of appetite, the

the juice of wild beets is mixed in their drink, and endeavours are uſed that they ſhould eat them, which if they can be brought to, they are the ſooner upon their legs; but if any aſthmatic ſymptoms appear in the ſheep, the tip of their ears is cut off, after which the paunch of a ſheep being thoroughly boiled in wine, a ſpoonful of the liquor is given to every ſheep; and this never fails, in a very little time, to ſet them to rights.

"The cough is ſo common a diſorder among ſheep, that one ſeldom paſſes near a flock without hearing it in ſeveral: yet in the Ardennes it is otherwiſe; for upon their firſt coughing, a radical cure is wrought by ſyringing, during ſix or eight days, up the ſheep's noſtrils, blanched almonds pounded in wine.

"It ſometimes happens that ſheep feed in paſtures intermixed with noxious herbs, which not ſeldom occaſion their belly to ſwell; and this, without a ſpeedy remedy, proves fatal; but, upon the firſt appearance of it, they are bled in the lip, and a ſpoonful of man's urine adminiſtered to them, which makes a perfect cure.

"If along with the graſs they have eat any worms or leaches, olive-oil, mixed with warm vinegar, is poured down their throats: this not only cures them of the preſent evil, but preſerves them from ſeveral other accidents.

"An abſceſs, or impoſthume, in the ſheep is cut, and ſalt, well pulverized and burnt with liquid pitch, ſtrewed over the inciſions.

"In order to make the ſheep good nurſes, ſo that they may be able plentifully to ſuckle two lambs, all they do is to bind dittany (in ſome places called pepper-wort) and trefoil to their bellies.

"Upon the lambs being ſick, a few ivy-leaves are given them to eat, which after a week ſo well reſtore them, that they ſuck very vigorouſly." *Muſeum Ruſticum*, *vol.* IV. *pag.* 420.

"There are, ſays Mr. Mills, in this kingdom, vaſt tracts of ground, known by the name of downs, on which are chiefly fed large flocks of ſheep. Experience has abundantly evinced, that though the graſs there is naturally ſhort, it is an excellent food for ſheep; and as the welfare of theſe creatures is of the utmoſt conſequence to one of the moſt eſſential branches of the commerce of England, very great caution ſhould be uſed in making any alteration in their diet, till it be well proved, by fair experiments, that a richer paſture does not injure their fleeces. I would therefore recommend, in the ſtrongeſt manner, to gentlemen who have eſtates bordering on ſuch downs, particularly on that extenſive tract called Saliſbury Plain, which reaches from the weſtward of Marlborough to the ſea, to bring ſome of their ſheep into rich paſtures, of different graſſes, as well natural as artificial, and to keep them there for ſome generations, in order to aſcertain with certainty, what the effect will be.---The word generations, may, perhaps, here terrify at firſt, as implying a long ſpace of time for theſe experiments, thoſe who do not immediately conſider in how few years this ſucceſſion may take place.---A lamb reared from its birth on, for inſtance, burnet, will, in two years, bring a lamb, which, in two years more, brings young, and the ſixth year may ſee the third generation: ſo that by the end of ſeven or eight years the fact may be aſcertained.

"If ſheep will be equally benefited by richer paſture, then the farther improvement of theſe downs muſt become a matter of great concern, both to individuals and to the public; becauſe, granting that they may be improved with ſafety, the number of our ſheep may be greatly increaſed: but if ſuch improvement ſhould be found in the leaſt detrimental to their wool, inſtead of being encouraged, it ſhould be forbidden, even by law." *Mills's Huſbandry*, *vol.* III. *page* 379.

SHEEP's-DUNG. *See the article* DUNG.

SHEEP's-*feſcue-graſs*. *See the article* GRASS.

SHEEP-LEASE, *Sheep-ſlate*, or *Sheep-walk*, paſture-land, appointed to the feeding of ſheep.

SHEER, pure, clean, unmixed.

SHELLS, a hard, and as it were ſtony covering, with which certain animals are defended, and thence called ſhell-fiſh.

The vaſt beds of foſſile ſhells found at great depths in the earth, as well as thoſe found lying on the ſea-ſhore, make an excellent manure for cold clayey lands. *See the article* CLAY.

SHEPHERD's-*Needle*, the name of a plant, ſo called from the remarkable ſhape of the ſeeds, with their appendage, reſembling the crane's bill.

SHIPPEN, a cow-houſe.

SHOEING *of horſes*, the operation of faſtening a piece of iron on the bottom part of a horſe's hoof.

The affair of ſhoeing horſes, is ſo important in its conſequences, both for the preſervation of the foot, the ſafety of the legs, and the eaſe of their motion, that we cannot be too attentive to any innovations, that may be recommended to us in this reſpect; we ſhall therefore give Mr. La Foſſe's ſentiments on this ſubject, with ſuch animadverſions as have occurred to us.

In order to underſtand this new method of ſhoeing, it is neceſſary firſt to premiſe the following obſervations, and attend to the anatomical plates before referred to.

It is moſt certain, that all horſes, except ſuch as have their feet overgrown, or ſuch as may have a particular occaſion of being ſhod, to preſerve the ſole, may, at any rate, go without ſhoes; and there are many examples, without mentioning the cuſtoms of Arabia, or Tartary, of horſes who are at daily work, without the leaſt need of ever being ſhod: but as we employ all our care, and addreſs, to hollow the foot, by paring it even to the quick, and to form an exact fine frog, it becomes abſolutely neceſſary to ſet ſhoes on them.

The original deſign of ſhoeing horſes, was undoubtedly intended as a preſervative of the hoof, and a defence of the ſole; but no one ſure could think it neceſſary to pare away, what he wanted to preſerve by the uſe of the ſhoes; becauſe that would be to act contrary to his firſt principles, and deſtroy his own work.

This precaution could never be recommended, but in caſes where the horny ſole is uneven, inſomuch, that the ſhoe could not bear equally upon it, which would take off from its neceſſary firmneſs; in ſuch a caſe, it may be reaſonable, otherwiſe it would be very abſurd.

Let us now obſerve the going, as well as the external, and internal ſtructure of a horſe's foot.

The horſe then who draws, preſſes firſt on the toe, then ſucceſſively on the ſides, to eaſe the toe; then the horſe's heel yields upon the heel of the ſhoe, from which it immediately riſes again.

The ſaddle, or pack-horſe, places the toe but lightly, ſo that the point of ſupport, is fixed neither upon the heel, or toe, but between both; which it is eaſy to demonſtrate anatomically.

Thus the cannon-bone preſſes on the paſtern, this on the coronary, the coronary upon the coffin, or foot-bone, and upon the nutbone.

By this deſcription of the bones, we may obſerve two eſſential things, which lay open the faults in the preſent method of ſhoeing, and points out the means of being able to remedy them for the future; one is, that the effort of the weight of a horſe, does not bear, either upon the toe, or heel, but on the middle, between both; the other ſhews, the greater the diſtance of the ſole from the ground, or from whatſoever point of ſupport, the more the puſhing the coronary-bone upon the nut-bone, will fatigue the nerve, or tendon upon which it reſts, by the inordinate diſtenſion it undergoes at every ſtep the horſe takes.

Thus we ſee, that by hollowing away the ſole in paring, the horſe is ſuſtained only upon the walls of the hoof, which having no aſſiſtance of ſupport from the horny ſole, is immediately worn, and battered by the weight of the horſe's body; and the ſooner he treads upon any hard ſubſtance, the ſooner he grows quite lame.

For by the connection, thickneſs, and flexibility, as well as contexture of the horny ſole, it ſeems to be wholly deſtined by nature, to ſerve, as a cuſhion to the fleſhy ſole, and tendon, which reſts upon it, in order to break the violent ſhocks of a pavement, ſtone, or any kind of ſtump, or external violence; but by paring it away in the cuſtomary manner, the horſe loſes his defence of nature, againſt ſtumps, nails, glaſs, &c. and thus the fleſhy ſole becomes eaſily bruiſed, or wounded.

It is obſervable, that a horſe ſeldom goes eaſy, or eſcapes being ſoon jaded, if the frog does not bear upon the ground, as it is the only point of ſupport to the tendon; ſo that if you keep it at any diſtance from the ground, by paring it away, an inordinate diſtenſion will happen to the tendon; which being repeated at every ſtep he goes, fatigues it, and cauſes an inflammation; whence alſo relaxations, defluxions, and tendinous ſwellings, eſpecially after long journeys, or hard riding, which are occaſioned more by the paring of the ſole, than the length of the journey; experience has ſhewn, that the frog neither ſuffers, or has ſhewn the leaſt ſign of fatigue, or ſenſibility, by being thus expoſed; and indeed from the ſtructure of it, it is ſcarce poſſible; for being of a ſoft ſpongy flexible ſubſtance, by its natural elaſticity, it yields to the weight of the body, the inſtant the horſe preſſes his feet to the ground, and immediately recovers it again; however, there is one caſe, whereby the frog may occaſion lameneſs, which is when it grows hard or dry; but by taking off the little end of the frog, this diſorder is ſoon remedied.

As the bad conſequences of paring away the ſole and frog, have been pointed out, and, I think, evidently proved, let us obſerve now, the ill effects of modern ſhoeing; for it is upon the form of the ſhoes, and the manner of ſetting them on, that not only the preſervation of the foot, but alſo the ſafety of their legs, and the eaſe of their motion depends.

In effect, the more eaſy our ſhoes ſet upon us, the more active we are; ſo a large, long, thick ſhoe ought to have the ſame effect upon horſes, that wooden ſhoes have upon us; that is, make them heavy, unwieldy, and hobling.

A long ſhoe is not only perfectly uſeleſs, but it is even prejudicial; for the horſe's heels coming to ſink upon thoſe of the ſhoes, the longer the lever, the greater will be the drag upon the clinches of the nails of the toe; and thus horſes will be more apt to ſtrike them off on many occaſions; eſpecially when they are apt to over-reach.

The longer the ſhoe is, and the more it covers the ſole, the more liable the horſe will be to fall, trip, and hobble in his walk; particularly if he goes on a pavement; becauſe the ſurface being formed of round parts, and the ſhoe having a large uniform hard face, he can ſcarce have above two or three points of ſupport.

It is thought by ſome, that ſtrong ſhoe-heels are an eaſe to the weak heels, and fetlocks of horſes; as if the body of the ſhoe was flexible enough to yield to the horſe's heel; and under this notion, they raiſe the ſhoe-heel, and leave a vacant ſpace between that and the horſe's heel; but the direct contrary happens, for it is the hoof, that by its flexibility yields to the ſhoe-heel, which is quite inflexible: the thicker the ſhoe-heel is, the more ſubject that of the horſe is to meet it, and inſtead of being eaſed, the horſe's heel becomes more compreſſed, as if in a conſtant vice, becauſe it has always the ſame point of ſupport.

By this means, they deprive them of the liberty of going with eaſe upon a pavement; becauſe the ſhoe does not bear upon a level, and produces an effect, like that of a pivot, upon the middle of the ſhoe-heels, and the vault, or hollow.

To obviate theſe inconveniencies, M. La Foſſe propoſes the following method of ſhoeing; that neither the ſole, or frog ſhould be pared at all; for neither will ever become too large by its growth; but in proportion as it grows, it will dry, ſcale, and fall off in flakes; that the edge of the hoof, if thought too long, ſhould be taken down as uſual; and then a ſhoe, in form of a half moon, ſet on, reaching the middle of the hoof; the heels may be thinned, and the ſhoes made a little longer for ſuch horſes as have weak hoofs.

Eight ſmall nails, made in the old way, that is, having very ſmall heads, are incruſted in the holes, which are made, as the head is, in an oblong form; the figures both of the ſhoe and nail, are to be ſeen in the plate. This is the whole myſtery.

By this method, the ſole is preſerved, and conſequently the foot defended againſt hard, or ſharp bodies, which the horſe may chance to tread on; thus inflammations, and dangerous compreſſions are avoided, and the many inconveniencies already mentioned, from the lodgment of ſand, gravel, or ſtones.

Another advantage ariſing from this method of ſhoeing, and preſerving the ſole, that natural defence againſt external injuries, is, that in not paring away the ſole, nor ſetting on any more ſhoe than is neceſſary to preſerve the horny ſole; the horſe will not be ſubject to ſlip, either on the winter's icey pavement, or the dry ſmooth one of the ſummer.

For by making a horſe walk upon the frog, and partly upon the heel, the former being ſtrongly rubbed, and puſhed againſt the ground, or pavement, impreſſes itſelf, as it were, by the weight of the horſe's body, into the inequalities, and interſtices it happens to meet in its way; by this means, the foot reſting on a great many more parts, which mutually eaſe it, by multiplying the points of ſupport, gives the animal a ſtronger adherence, and more ſecurity upon the place he goes.

By paring away the ſole, the air when it is in this thin ſtate, penetrates, and dries it to ſuch a degree, that by its contraction, it compreſſes the fleſhy ſole, ſo as to lame the horſe.

By

By this means, alſo ſand, and gravel get in, and are ground between the ſole, and ſhoe; and again between the horſe's heel, and thoſe of the ſhoe; which not readily coming out again, cauſe compreſſions, inflammations, &c. which laſt accidents are very often the effects of a ſtone's being wedged in between the ſhoe-heels.

To recapitulate the whole.

The weight of the ſaddle horſe does not preſs upon the toe, or heel, but on the middle between both; ſo that the greater the diſtance of the ſole from the ground, or from whatever point of ſupport, the more the great tendon will be fatigued, by the inordinate diſtenſion it undergoes at every ſtep.

The more the ſole is covered by the ſhoe, the more the horſe will ſlip, ſlide, or fall; becauſe the ſurface being formed of round parts, and the ſhoe having a large uniform hard face, he can ſcarce have above two or three points of ſupport; ſo that the greater contact the horſe's foot has with the ground, the more points are multiplied; and the ſafer of conſequence he goes.

By ſhoeing, no other intention could be expected, but preſerving the hoof, after paring away its luxuriancy.

That long ſhoes, and raiſing the ſhoe-heel, is a very pernicious cuſtom.

By paring away the horny ſole, it hardens in proportion to its being thinned, and by compreſſing the fleſhy ſole, makes a horſe lame; he loſes alſo the defence of nature againſt external bodies, by which means, the fleſhy ſole becomes often wounded, bruiſed, &c.

By paring the frog ſo much away, that it is not in contact with the ground, the tendon will be inordinately diſtended: by which means, it becomes ſubject to inflammation, relaxation, defluxion, and rupture.

Laſtly, It appears from the anatomy of the foot, that horſes are chiefly lame in thoſe bones and its tendon; that the preſent method of ſhoeing contributes greatly thereto, by paring away the horney ſole, and hollowing the foot; by which means, the fleſhy ſole becomes more expoſed to accidents, and the tendon fatigued, ſtrained, and ruptured; its ſupport being taken away by paring the frog.

We may learn alſo from hence, that no more of the toe ſhould be pared away, than to keep the foot uniform with the ſhoe; that the ſhoe ſhould be made flat, in order to adapt itſelf the better to the foot; not made too thick, or hollow, nor projecting beyond the horſe's heel.

This is the ſubſtance of M. La Foſſe's new method of ſhoeing; which from its ſimplicity, and the great eaſe of performing it, ſeems to demand our regard and attention; but though it appears well calculated for the flat pavements, and roads of France, yet we doubt its general ſucceſs with us; eſpecially in ſome of our rough ſtony countries, where the heel, and frog, being left ſo intirely defenceleſs, might be liable to frequent injuries from ſuch irregular looſe bodies, as flints, looſe ſtones, &c. We ſhould ſuſpect alſo its ſucceſs, on moiſt, greaſy, and ſlippery ſoils, or chalks; where the ſhoe heel, or cramps, ſeems of great uſe, to ſupport a horſe, by the impreſſion it makes in the ſurface; how inconvenient ſoever it may be in other reſpects: tho' it muſt be confeſſed, from our method of ſhoeing race horſes, where the whole foot comes into immediate contact with the ground, notwithſtanding the courſe they run over is often very ſlippery, yet they ſeldom fall.

But though this method may not be ſo generally adopted by us, in its utmoſt extent, for the reaſons above given; as well as from the different texture of horſes feet, which in ſome will always demand a particular method of ſhoeing; yet it undoubtedly may ſuit many horſes, and many different parts of the kingdom; and this particular advantage every one may reap from it, viz. to pare away as little of the ſole and frog as poſſible, even in the old method of ſhoeing: the many inconveniencies of which, we apprehend, have been ſufficiently pointed out, and amply explained; and would, by this means, be in a great meaſure obviated.

EXPLANATION of Fig. 1, 2, 3, 4, Plate XXIV.

Fig. 1. repreſents the bottom of a horſe's foot.

a. a. a. is the horny ſole.

b. the frog.

2. The hoof towards its lower edge, called by the author the wall of the foot.

Fig. 2. ſhews the horny ſole *a.* raiſed from the fleſhy ſole *c. c. c.* round which is the enchannelled fleſh, 6. placed in the ſulcus of the inner ſurface of the hoof: 5. the horny part of which is ſoft and white.

Fig. 3. repreſents the under part of the fleſhy ſole *c.* raiſed from the foot-bone, or what Gibſon calls the coffin-bone *d. d. d.* *g.* the covering or ſheath of the Tendo Achillis. 2. The cartilage. 6. The edge of the fleſhy ſole confined in the furrow of the channelled horny ſubſtance. *Bartlet's Farriery, page* 352.

SHOODS, oat hulls.

SHOVEL, a well known inſtrument, conſiſting of a long handle, and a broad blade, with raiſed edges.

SHOWEL, a blind for a cow's eyes.

SHROUD, a ſhelter, or harbour.

SHUCK, a huſk or ſhell.

SICKLE, a toothed hook, with which corn is reaped.

SIEVE, hair, lawn, or baſket-work, ſtrained on a hoop, for ſeparating the flour from the bran, the duſt from corn, &c.

SIG, urine, chamber-lie.

SIKE, a little rill, a water furrow, a gutter.

SILVER-WEED, or *wild Tanſey*, a ſpecies of cinquefoil, which grows naturally upon cold ſtiff land in moſt parts of England, and is a ſure mark of the ſterility of the ſoil. Its ſtalks ſpread upon the ground, and ſend out roots from their joints; by which means, and by the frequent ſhedding of its ſeeds, for it flowers during the whole ſummer, it ſoon over-runs, and fills the land to a great diſtance. The leaves of this plant are compoſed of ſeveral lobes or wings, which are generally placed along the mid-rib, and terminated by an odd one: they are jagged at their edges, and are of a ſilvery colour, eſpecially on their under ſide. The way to deſtroy this kind of growth has been already pointed out. Mr. Ray ſays, that the root of wild tanſey, which is ſomewhat of the parſnip kind, is good to eat, and that hogs are very fond of it.

SIMPSON, groundſel.

SIT-FAST, a part of a horſe's hide turned horny, and which if it cannot be diſſolved, and ſoftened by rubbing with mercurial ointment, muſt be cut out, and afterwards healed as a freſh wound. It generally proceeds from a warble. *See the article* WARBLE.

SIZZING, yeaſt, or barm.

SKID, the chain by which the wheel of a waggon is faſtened, ſo as to prevent its turning round, upon deſcending a ſteep hill.

SKILLING,

SKILLING, an iſle, or bay of a barn.

SLAB, the out-ſide plank of a piece of timber when ſawn into boards.

SLECK, ſmall pit-coal.

SMUT, a diſtemper incident to corn, and which, according to M. Duhamel, may be diſtinguiſhed by the following marks.

" 1. This diſtemper deſtroys entirely the germe and ſubſtance of the grain.

" 2. It affects not only the ear, but alſo, in ſome degree, the whole plant, when it has made a great progreſs.

" 3. It very ſeldom happens but that when one ſtalk is ſmutty, all the ears of the other ſtalks from the ſame root are ſo too.

" 4. So early as in March or April, upon opening carefully the hood or blades which cover the ear, and examining the young ear, then not above the ſixth part of an inch in length, and almoſt cloſe to the roots, I found this embryo already black, and attacked with this diſtemper. Perhaps it may not always ſeize the plants ſo early.

" 5. When the diſtempered ear comes out of its coverings formed by the blades, it looks lank and meagre; the common and immediate coverings of the grains are in this caſe ſo very ſlight and thin, that the black powder is ſeen through them; and from this time nothing is found, in lieu of grain, but a black powder, which has a fetid ſmell, and no conſiſtency. As this powder, of which the conſtituent particles have but very little coheſion, and of which the coverings are deſtroyed, is eaſily blown off by wind, or waſhed away by rain; the huſbandman, in houſing theſe plants, houſes only ſkeletons of the ears. If any impreſſion of this powder remains, it is eaſily taken off by ſifting: but I have not experienced it to be contagious, like that of burnt-grain.

" M. Tillet, who gained the prize propoſed by the Academy at Bourdeaux for the beſt account of what renders black the mealy ſubſtance of grain, has obſerved that theſe corrupted ears are often found to be vitiated even in the hood, though this laſt looks as green and perfect as if nothing ailed the corn within. The upper part of the ſtalk of a ſmutty plant is not, commonly, quite ſtrait, from within about half an inch below the ear. If ſuch a ſtalk is ſqueezed there, it ſcarcely yields at all to the preſſure. If it be cut aſunder at about a ſixth part, or a quarter of an inch, below the ear, it will be found to be almoſt entirely filled with pith, in ſuch manner that only a very ſmall opening can be perceived in the heart of this ſtalk, inſtead of the large pipe that is in healthy ſtems. M. Tillet concludes from hence, that the circulation of the juices is obſtructed in the upper part of the ſtalk of ſmutty plants.

" Bearded wheat is apt to be ſmutty, as well as that which is not bearded; but neither M. Tillet nor I have ever met with a ſmutty ear of rye.

" Cauſes of ſmut.—The ſmuttineſs of corn cannot be owing to a want of fecundation, as many have hitherto miſtakenly imagined; ſince it affects and deſtroys the organs of both ſexes long before the time of that fecundation.

" It cannot be imputed to the ſettling of wet upon the ears, or to fogs, or to a violent impreſſion of the ſun; ſince we have ſeen the ears ſmutty long before they ceaſed to be covered with the blades, which continue green till the diſtemper has made a great progreſs.

" The ſame obſervations refute abſolutely the opinion of thoſe who ſuppoſe the cauſe of the ſmut to be in the grains, after they are formed, and before they are paſt their milky ſtate.

" The ſmut of corn has been alſo aſcribed to the moiſture of the earth: but we do not ſee more ſmutty plants in the loweſt, and conſequently wetteſt parts of a field, than in the higheſt and moſt dry. Beſides, why ſhould there be a ſingle ſmutty plant in the midſt of numbers of ſound ones? However, as it appears that corn is more frequently attacked with this diſtemper in wet years, than when the ſeaſons are dry; too much moiſture may perhaps, without being the immediate cauſe of the ſmut, favour its progreſs more than drought would do.

" Some naturaliſts have aſcribed this diſtemper to inſects. If I am not authoriſed abſolutely to deny this, I can at leaſt aſſert that, after having been of this opinion for ſome time, all my endeavours to eſtabliſh it by facts have proved ineffectual. Some obſervers have indeed ſhewn me different inſects in ſmutty grains; but as I found the very ſame kinds likewiſe in ſound ears, I believe, with M. Tillet, that they are not in any manner the cauſe of this diſtemper. We know that the corn-caterpillar devours the mealy ſubſtance of the grain: but it does not occaſion ſmut. Numbers of flies lay their eggs upon theſe ſeeds; and the worms and maggots which proceed from them, eat the ſeeds: but this does not occaſion any thing like ſmut. The Reverend Dr. Hales, to ſatisfy himſelf whether the ſmut of corn might not proceed from the ſeeds being bruiſed by the flail, took a number of grains of different ſizes, and bruiſed them with a hammer. They grew well, and bore ears which were not ſmutty. Thus his own experience convinced this ſkilful philoſopher, that he had conceived a wrong idea of the cauſe of this diſtemper.

" Several cultivators have thought that pigeons dung and that of ſheep render corn ſmutty: but this is a groundleſs notion. We have large pigeon-houſes, the dung of which is ſtrewed upon our wheat lands: the ſame is done with the dung of our ſheep, and we even fold our flocks upon thoſe lands: yet we do not find that theſe fields are more infected with ſmut than others. This allegation is therefore abſolutely deſtitute of proof.

" Wolfius was of opinion that the ſmut of corn proceeds from a monſtroſity of the embryo: but M. Aimen has refuted that ſuppoſition, by ſhewing that the male flowers of certain kinds of plants are attacked with this diſtemper: now the flowers have not any embryo.

" M. Aimen, M. D. has very judiciouſly obſerved, that the ſmut of corn cannot derive its origin from a defect in the ſap; as all the parts of the plant, except the ear, look healthy, and there are plants whoſe roots are perennial, which appear vigorous, though their ſeeds are ſmutty every year. He is of opinion, that whatever weakens the plant is apt to bring on the ſmut, and inſtances, as a proof of this, that it is a frequent cuſtom in his country to cut rye as ſoon as it ſpindles, for food for their cattle; and that this rye generally produces other ears, which ſeldom contain any but diſtempered grain: to which he adds, that ſeed-corn which had been pricked or run through with a needle; or which is not throughly ripe, and that which produces lateral or ſecond ears, is ſubject to the ſmut.

" The ſame obſerver, who has made ſeveral careful reſearches into what is properly called the ſmut of corn, holds that this diſtemper proceeds from an ulcer which attacks firſt the parts that ſuſtain the ſeeds, and afterwards ſpreads to the reſt of the flower. But, ſome will ſay, what

is the primary cauſe of that ulcer? In order to diſcover it, M. Aimen examined ſeveral grains of barley with a microſcope: ſome of them were bigger than others: ſome were very hard; and others yielded to the preſſure of his nail: ſome were of a deeper, and others of a lighter colour; ſome longer, and others rounder, than they ought to have been: their rind was ſometimes wrinkled in ſeveral places, whereas in its natural ſtate it is ſmooth: and laſtly, he perceived upon ſome of them black ſpots, which, when examined with a magnifying glaſs, appeared to be covered with mould. Theſe grains were ſeparated carefully, according to their ſeveral conditions, and ſown apart, though in the ſame ground. All the mouldy grains produced ſmutty ears, the ſhrivelled, the parched, and thoſe that were attacked by inſects, either did not grow at all, or did not produce any ſmut.

"He then ſingled out a parcel of ſound grains, ſowed them, and ſome time after took them up in order to examine them again with a magnifying glaſs. He found ſome of them mouldy, replanted them all, and obſerved that the mouldy grains produced ſmutty ears.

"M. Aimen, without pretending that this is the only cauſe of the ſmut of corn, concludes from theſe experiments, that mouldineſs is a cauſe of this diſtemper.

"It is very hard to conceive how mouldineſs can produce this diſtemper; for as ſoon as the ſeed has ſprouted and produced its plant, the whole ſubſtance of the grain is conſumed. Whether the hulls or coverings grow mouldy or not, ſeems to be a circumſtance quite immaterial to the plant, which ceaſes from that time to ſubſiſt on what the ſeed had ſupplied it with till then. We readily conceive that if this mouldineſs attacked the plant, it might either kill it or render it poor and weak: but we cannot imagine how this mouldineſs ſhould affect only the organs of fructification, and entirely deſtroy them, without doing any viſible injury to the other parts of the ſame plant, even though it be a perennial. However, M. Aimen relates facts; to account for which one might conjecture, ſuppoſing the increaſe of plants to be only an extenſion of the embryo, that the organs of fructification which exiſt in imperceptible miniature in the ſeed, were already affected by the mouldineſs before the grains were depoſited in the earth. But let us abide by well obſerved facts: it being of more importance to collect them, than to be in a hurry to explain them by conjectures hitherto attended with little probability.

"Means of preventing this diſtemper.—M. Aimen is of opinion, that, to prevent this diſtemper, the fineſt and ripeſt corn ſhould be choſen for ſeed, that it ſhould be threſhed at ſoon as poſſible, and that it ſhould be limed immediately after, as well, ſays he, to keep it from growing mouldy, as to deſtroy the mould already formed, if any ſuch there be; adding, that every method he has tried to make corn ſo prepared grow mouldy, has been ineffectual, and that he has never known it produce ſmutty ears."

According to this principle, the preparations which have been experienced to be ſerviceable in the caſe of burnt-grain, and particularly M. Tillet's lye, may be equally beneficial to guard againſt ſmut. But we ſhall not attempt, continues M. Duhamel, to make any addition to M. Aimen's advice, becauſe we have not ſtudied the diſtemper properly called ſmut, ſo much as we have that far more dangerous one which we diſtinguiſh by the name of burnt-grain. According to ſome experiments made by M. Tillet, the black powder of ſmutty corn does not appear to be contagious. However, we ſhould ſpeak more affirmatively on this point, if we had been able to collect a ſufficient quantity of that powder: but, as was ſaid before, the wind and rain carry it away, and but very little of it is found in granaries. We exhort thoſe who wiſh to contribute to the progreſs of agriculture, to make farther trials, in order to aſcertain whether the ſmut of corn be really contagious or not: but at the ſame time we caution them to be careful not to confound this diſtemper with the uſtilago, or burnt-ear; for want of which diſtinction ſeveral philoſophers have hitherto been miſled.

As weak plants are moſt ſubject to ſmut, M. Aimen recommends good tillage, as a ſure means of giving them ſtrength and vigour. It is probably for this reaſon that corn is very ſeldom ſmutty when managed according to the New Huſbandry.

He obſerves, that all the lyes generally made uſe of, preſerve the plants from mouldineſs; and of all of them, lime ſeems to him the moſt effectual.

"M. de Lignerolle ſays, that the ſureſt means of avoiding ſmut, and that which he has practiſed with ſucceſs ever ſince the year 1739, on upwards of three hundred acres of land, is, to change the ſeed every year, to be very careful that the ſeed-corn be well dried and thoroughly ripe, and that it be not ſmutty, nor have any ſmutty powder ſticking to it. He then pours boiling water on quick-lime, in a large tub; and after the ebullition is over, as much cold water as there was hot, and ſtirs it all ſtrongly together, in order to diſſolve and thoroughly mix the lime. The quantity of wheat intended to be ſowed is ſprinkled with this lye, and then well ſtirred with a ſhovel, and laid in as high a heap as poſſible. It is beſt to keep the grain for a week after this preparation, turning it every day; for otherwiſe it would heat ſo as to deſtroy the germe. By theſe means he has not had any ſmut, when the fields around him have been infected with that diſtemper.

"M. Donat, near Rochelle, thinking the ingredients commonly employed in ſteeps too dear for the uſe of farmers, ſtudied for ſome years to find out ſomething cheaper, eaſy to be had every where, and therefore better calculated to be of general uſe. "I have had, ſays he, in a letter to M. Duhamel, the good fortune to accompliſh what I wiſhed; for I now uſe only pidgeons-dung, quick-lime, aſhes, and ſea-ſalt, where this laſt can be conveniently had. I have ſometimes made with theſe ingredients, ſteeped in water, ſo ſtrong a liquor, that it has even deſtroyed the germe of the grain. But there will be no danger of that, if care is taken to obſerve the following directions, which are the reſult of ſeven years ſucceſsful experience, even at times when farmers who have neglected to follow my example, have had ſuch wretched crops as have not paid the charge of reaping.

"Take quick-lime and pigeons-dung, of each twenty-five pounds, forty pounds of wood-aſhes, and twenty-five pounds of ſea-ſalt, or ſalt-petre. Put all theſe into a tub large enough to hold half a hogſhead of common water added to them. Stir them all well with a ſtick, till the lime is quite diſſolved. This lye will keep ſome time without ſpoiling. It muſt be ſtirred again juſt before the corn is ſteeped in it. The grain is then put into a baſket, and plunged in the lye, where it remains till it has thoroughly imbibed it; after which it is taken out, and laid in a heap, till it is quite drained of all its moiſture:

or, which is a ſtill better way, take a maſhing-tub, fill it with grain to within four inches of the brim, and then pour in the lye well ſtirred before hand. When the tub is full, let the lye run out at the bottom, into ſome other veſſel, in order to uſe it again for more corn. Let the grain be then taken out and laid in a heap to drain; and continue in this manner to ſteep all your ſeed-corn. The wheat thus prepared may be ſowed the next day, and muſt not be kept above five or ſix days, for fear of its heating. This I ſay from experience. The quantity of lye above preſcribed, will ſerve to prepare twenty buſhels of wheat.

"Mr. Tull obſerves, that brining, and changing the ſeed, are the general remedies for ſmut. The former of theſe, he had heard, was diſcovered about ſeventy years before he wrote, by the ſowing of ſome wheat which had been ſunk in the ſea, and which produced clean corn, when it was a remarkable year for ſmut all over England: but he afterwards doubts whether this might not happen by its being foreign ſeed, and therefore a proper change for our ſoil. He tells us that two farmers, whoſe lands lay intermixed, uſed ſeed of the ſame growth, from a good change of land, and that the one, who brined his ſeed, had not any ſmut, whilſt the other, who neglected that precaution, had a very ſmutty crop—But again he doubts whether this ſeed might not have been changed the year before, and ſo might not be greatly infected; or at leaſt not more than the brine and lime might cure. He adds, that ſmutty ſeed-wheat, though brined, will produce a ſmutty crop, unleſs the year prove very favourable; for that favourable years will cure the ſmut, as unkind ones will cauſe it: but, above all, he aſſures us, that the drill-huſbandry is the moſt effectual cure."

"Count Ginanni, a patrician of Ravenna, who has favoured the world with a very accurate and ingenious treatiſe on the diſtempers of corn in the blade, deems the ruſt incurable, after it has once taken place. He has prevented it by ſprinkling the plants, before their ears were formed in their hoods, with a ſolution of ſal ammoniac or ſalt-petre in water mixed with ſalt of tartar, and with other alkaline ſubſtances; but obſerves, that ſuch preparations are too dear for the uſe of farmers. He thinks, that ſowing thin and keeping the corn quite free from weeds, will generally be a good preſervative, as he himſelf has frequently experienced."

"The ſmut in wheat, ſays a writer in the Muſeum Ruſticum, is an evil which has long been complained of, and many methods tried to prevent it, all of which have proved ineffectual, or, at beſt, but a mitigation of the diſeaſe; which methods I need not here enumerate, as they are generally known, or are to be met with in various authors who have wrote on agriculture: ſome of them being calculated to forward vegetation, and ſtrengthen the plant, ſuch it will be adviſeable to continue in the practice of.

"But amongſt all the authors who have wrote on this ſubject, I do not remember to have ſeen one who has pointed out a probable conjecture with reſpect to the cauſe of this malady, ſo as to be ſupported by any tolerable degree of reaſon. And inaſmuch as natural hiſtory has been and is my favourite ſtudy, (of which I take agriculture and a knowledge of cattle to be no ſmall part) I have frequently employed ſome leiſure hours, to endeavour to aſſign cauſes for various diſeaſes, to which the productions of the earth are ſubject; among which, this of ſmut in wheat is one. And being deſirous to improve my knowledge, I am willing to communicate, that if any thing worth notice might come from me, I may have the pleaſure of doing ſomething for the public good, and thereby induce others to make their diſcoveries known, from which myſelf, as well as many more, may reap ſome advantage.

"I remember to have read a little treatiſe, wrote ſome years ſince, by James Logan, (chief juſtice, and preſident of the council, of the province of Penſylvania) on the generation of plants, containing obſervations made on the maize, by which he diſcovered that plant to be (what Linnæus calls monoecia, or) a plant bearing male and female flowers, and, as ſuch, capable of being impregnated with a fructifying duſt from another plant of the like kind.

"I own, the reading this pamphlet firſt gave me the hint of the generation of vegetables, from which I continued my obſervations reſpecting other plants, and among the reſt to wheat, and the like; though this is not of the ſame claſs with maize, but of the claſs triandria of Linnæus, and is hermaphrodite, yet, nevertheleſs, equally ſubject to be impregnated by duſt from another plant, as well as with duſt from itſelf.

"Having frequently obſerved amongſt wheat, while green, (though ſhot up into ſpindle) ſeveral black, blighted ears, I examined them, and found theſe were ears in which, by ſome accident, the intention of nature was prevented; I ſuppoſe, by being detained too long in the hoſe, and by the natural humidity of the plant, a fermentation was promoted in its ear, deſtroying the ſmall veſſels through which the corns were to receive nouriſhment; by which means their contents became black, dry, and duſty: theſe ears, growing up with the others, imbibe moiſture ſufficient to cauſe the duſty particles in the grains in them to expand, and burſt the fine ſkin which contained them: being thus ſet at liberty, the air, if it happens to be a dry ſeaſon, dries them again; by which means they become light enough to float therein, when ſeparated from the ſkin which held them. If this happens when the wheat is in bloſſom, which it often does, part of this duſt enters the ſtygma of healthy corns, and thereby infects them: the pulp in thoſe becoming black, a fermentation is raiſed therein, which deſtroys the life of the grain thus impregnated: hence the diſagreeable ſmell is acquired peculiar to this diſeaſe (the ſmell in a grain of ſmut being the ſame as in a black blighted ear.)

"From hence it is eaſily accounted for, why, often, a few grains in an ear are ſmutty, and the others good.

"Some may perhaps object, if this be the caſe, why are not barley and oats ſubject to the like diſeaſe, ſince both theſe are ſubject to the black blight as well as wheat? Such objectors would do well to obſerve, that theſe have a more tough ſkin than wheat, which does not burſt till after the blowing of theſe ſorts of corn is over; therefore, when it does burſt, the duſt can do no harm.

"Having thus pointed out the cauſe, I now proceed to preſcribe the remedy, which is, when the corn is ſhot into ſpindle, and the ears begin to appear, let ſome perſons go along each furrow in the field, and carefully break off all ears of the black kind, (not pull them up, becauſe often from the ſame root grow ſeveral others, which are good and ſound ears) and when broke off put them into a bag, and carry them away; for ſhould they be thrown on the ground, there may ſtill be danger of infection from

from them; and as, 'tis poſſible, there may be ſome of theſe diſeaſed ears, which are not burſten, and therefore may eſcape being gathered, theſe may be known by the ſtalk at the neck being crooked, and bent in the length of three or four inches backward, and forward five or ſix bends, and the hoſe nearer to the head of ſuch than the ears which are good.

"The ſeaſons in which wheat is moſt liable to be ſmutty are, it is well known, ſuch in which it happens to be dry weather and windy at the time of blowing; but if it happens to be wet during that time, it is very rare to ſee a ſmutty ear in a field." *Muſeum Ruſticum, vol.* II. *page* 19.

"As the ſmut in wheat, ſays another writer in the ſame work, is an evil greatly complained of, and not without reaſon, among farmers, I have no doubt but your readers will be well pleaſed to be informed of a means of preventing the damage which is annually experienced in this reſpect.

"As I write from experience, what I communicate may be depended on; and I have great foundation for thinking it will be found of particular ſervice to ſuch of your readers as are practical farmers, and who yet are unacquainted with the method I intend to recommend.

"I have for many years paſt, eſcaped having ſmutty crops, by a proper care of the ſeed-wheat before it is put into the ground; and the method I purſue, though efficacious, is in itſelf ſimple and cheap.

"I take four buſhels of pigeons dung, which I put into a large tub: on this I pour a ſufficient quantity of boiling water, and, mixing them well together, let them ſtand ſix hours, till a kind of ſtrong lye is made, which, at the end of that time, the groſſer matter being ſubſided, I cauſe to be carefully drained off, and put into a large keeve, or tub, for uſe.

"This quantity is ſufficient for eighty buſhels of ſeed-wheat.

"My next care is to ſhoot into this ſteep a manageable quantity of my ſeed, which is immediately to be violently agitated, with either birchen brooms, or the rudders that are made uſe of in ſtirring the malt in the maſh-tub in a brewing-office. As the light grains riſe, they muſt be diligently ſkimmed off; and after the ſeed has been agitated in this manner for the ſpace of perhaps half an hour, it may be taken out of the ſteep, and ſown out of hand, with great ſafety: and I can venture to ſay, that if the land is in good heart, and has been properly tilled, it will not, when ſown with theſe precautions, produce a ſmutty crop." *Muſeum Ruſticum, vol.* III. *page* 81.

Another gentleman, who ſigns himſelf a Norfolk farmer, declares he always obſerved, that if the ſeed was well waſhed it never failed: that he took the hint, and waſhed ſome ſeed which he knew to be ſmutty, in a large tub filled with plain ſimple water, ſtirring it violently with birchen brooms, taking care, from time to time, to ſkim off the light. This anſwered very well, and he has ever ſince continued the practice.

"I read, ſays another gentleman, the above account with ſome degree of ſatisfaction, but am ſorry that your correſpondent ſhould be ſo much a lover of brevity, as to ſay no more on a ſubject of ſuch infinite importance.

"The truth is, we Engliſh farmers have hitherto known very little of the nature of this diſeaſe in wheat, imagining that whenever the corn was black it was infected with the ſame diſorder; but this is far from being the caſe, as any of your readers may ſee, by referring to a piece written by Monſ. de Gonfreville of Normandy, publiſhed in the ſecond number of the Foreign Eſſays on Agriculture, &c. (which I cannot but eſteem a very uſeful work) and containing a detail of a number of experiments made by the above gentleman to aſcertain the cauſe of the ſmut.

"I was not a little pleaſed to find that the method preſcribed in this invaluable Eſſay, for guarding againſt this diſtemper, does not materially differ from that above recommended.

"Both theſe gentlemen depend on the clean waſhing of the ſeed, and the trials of both met with the wiſhed-for ſucceſs."

We ſhall conclude this article with the following method of preventing this deſtructive diſtemper, ſent us by the ingenious Mr. Bromwell Powell, of Green's Forge, near Stourbridge in Worceſterſhire, dated September 1766.

"I have here, ſays he, ſent you an infallible remedy againſt the ſmut in wheat, a thing ſo prejudicial to the community in general, and which I myſelf have made uſe of for ſeveral years paſt, and have ſown ſmutted wheat, prepared as under directed, and have not had one ſmutted ear from the produce; and am well aſſured if the farmers will obſerve the under direction, they never will have any. Now as the coating of wheat with brine and lime, is ſo well known to the farmers in general, I need ſay no more on that ſubject, as you have directions from many authors concerning it: but when wheat is ſo prepared with brine and lime as is uſual, then to every ſtrike of wheat ſo prepared, add one pound and a half of red lead, by putting it into a cullinder and ſhaking it gently over the prepared corn, and ſometime ſtirring the corn with a ſhovel, that every corn may have a ſpot or two of the lead adhere to it, which when ſo done is an effectual preſervative againſt the above malady, nor will any fowls lie upon it after ſo prepared.

"By the above method ſeveral of the penurious farmers will look upon it to be a great expence, as the lead will coſt, bought in ſmall quantities, three-pence per pound; but admit every ſtrike was to coſt ſix-pence per ſtrike, it would greatly anſwer the farmer's purpoſe: I therefore have ordered as ſmall a quantity as can be complied with; but if more was added it would ſtill be a greater preſervative. As the time of ſowing is now near at hand, I hope the gentlemen will apply to ſome farmer, whom they can depend upon, to try the experiment of one ſtrike ſo prepared; and, if they can readily procure it, let half a ſtrike of it be ſmutted corn when ſown, and to that half ſtrike would adviſe one pound of the lead to be applied, which will be a convincing proof of the utility of the above."

SNAIL-COD, or *Snag-greet*, a name given by Mr. Worlidge, to a ſpecies of manure, found at the bottom of deep rivers. It is a kind of mud or ſludge, very ſoft, full of wrinkles, and intermixed with many little ſhells and ſnails, to which it is thought to owe a great part of its fatneſs.

SNATHE, the handle of a ſcythe.

SOAP-ASHES. *See* ASHES.

SOIL, a general name for all ſorts of land. *See the articles* EARTH *and* GROUND.

Soils are divided by our farmers into nine ſorts, viz. the ſandy, the gravelly, the chalky, the ſtony, the rocky, the hazely, the loamy, the marſhy, and the clayey. *See the articles* SAND, GRAVEL, CHALK, &c.

SOOT, a fuliginous ſubſtance formed in chimnies.

Soot, either of vegetables or of coal, is good both for corn and graſs, eſpecially on cold moiſt grounds, or lands

apt to be over-run with moſs. Many have found their account in ſtrewing it early over their green wheat and barley: but Mr. Ellis ſays neither of them ought to be ſooted after the 25th of April, becauſe the wheat, and generally the barley, have then done gathering and branching, and are upon the ſpindle. He likewiſe thinks it proper to be ſown over young turnips, juſt after they have appeared. But care ſhould always be taken not to ſtrew it too thick, leſt its hot nature ſhould hurt the plants. Mr. Worlidge ſeems to think wood-ſoot the beſt: but Mr. Mortimer prefers that which is made from ſea-coal, of which about forty buſhels are commonly allowed to an acre; though ſome grounds will require more: to which he adds, that it produces a very fine ſweet graſs, and deſtroys worms and weeds; and that it ought not to be ſown upon wheat till Candlemas, becauſe the long cold rains and ſnows are apt to waſh it in too ſoon: nor is it ſafe to lay it on later, leſt a drought ſucceed and burn it up. *See the article* COAL-SOOT.

SOUR LAND, a cold clayey ſoil. *See the article* CLAY.

SOW, the female of the ſwine. *See* HOG.

SOWING, the action of ſcattering the ſeeds of plants in the ground.

Writers of different countries mention the uſual ſeaſons for ſowing their ſeveral kinds of grain, but do not take notice of any ſign by which the huſbandman may be directed when to ſow his corn with the greater chance of ſucceſs. For a rule of this kind we are indebted to the juſtly celebrated Linnæus, a man truly great, not only for his unequalled knowledge in natural hiſtory, and his indefatigable induſtry in the purſuit of that ſcience; but even ſtill more ſo for his diſintereſted zeal to turn the reſult of his ſtudies to the advantage of his country. Far ſuperior to that mean jealouſy which little minds are apt to entertain on their diſcoveries, he nobly calls forth every aſſiſtant, and invites each of them to become his rival in promoting the general welfare of mankind, as we are particularly informed by one of his diſciples.

"It is now the fourth year, ſays the ingenious Mr. Harald Barck, a member of the Swediſh academy, ſince our illuſtrious preſident exhorted his countrymen to obſerve with all care and diligence, at what time every tree expands its buds, and unfolds its leaves; imagining, and not without good reaſon, that our country would, ſome time or other, reap ſome new, and perhaps unexpected benefit, from obſervations of this kind made in different places."

As one of the apparent advantages, he adviſes "the prudent huſbandman to watch with the greateſt care the proper time for ſowing; becauſe this, with the divine aſſiſtance, produces plenty of proviſion, and lays the foundation of the public welfare of the ſtate, and of the private happineſs of the people. The ignorant farmer, tenacious of the ways and cuſtoms of his anceſtors, fixes his ſowing ſeaſon generally to a month, and ſometimes even to a particular day, without conſidering whether the earth be prepared to receive the ſeed: from whence it frequently happens, that the fields do not return what might be expected, and that what the ſower ſowed with ſweat, the reaper reaps with ſorrow. The wiſe œconomiſt ſhould therefore fix certain ſigns whereby to judge of the proper time for ſowing. We look up to the ſtars, and without reaſon, ſuppoſe that the changes on earth will anſwer to the heavenly bodies; entirely neglecting the things which grow around us. We ſee trees open their buds and expand their leaves, from whence we conclude that ſpring approaches, and experience ſupports us in this concluſion: but no body has hitherto been able to ſhew what trees Providence intended ſhould be our calendar, ſo that we might know on what day the countryman ought to ſow his grain. No one can deny but that the ſame power which brings forth the leaves of trees, will alſo make the grain vegetate; nor can any one juſtly aſſert that a premature ſowing will always, and every where, accelerate a ripe harveſt. Perhaps therefore we cannot promiſe ourſelves a happy ſucceſs by any means ſo likely, as by taking our rule for ſowing from the leafing of trees. We muſt, for this end, obſerve in what order every tree puts forth its leaves, according to its ſpecies, the heat of the atmoſphere and the quality of the ſoil. Afterwards, by comparing together the obſervations of ſeveral years, it will not be difficult to define, from the foliation of trees, if not certainly at leaſt probably, the time when annual plants ought to be ſown. It will be neceſſary likewiſe to remark what ſowings made in different parts of the ſpring produce the beſt crops, that by comparing theſe with the leafing of trees, it may appear which is the moſt proper time for ſowing; nor will it be amiſs in like manner to note at what times certain plants, eſpecially the moſt remarkable in every province, blow; that it may appear whether the year makes a quicker or ſlower progreſs. In upland, the ſowing of barley nearly coincides with the foliation of the birch."

Mr. Stillingfleet, who has given us a judicious tranſlation of ſome ſelect pieces publiſhed by ſeveral ingenious members of that great, and hitherto unrivalled ſchool of natural hiſtory, the univerſity of Upſal in Sweden, under the preſidence of the excellent Linnæus, was told by a common huſbandman in Norfolk, that when the oak catkins begin to ſhed their ſeed, it is a proper time to ſow barley: "and why," adds he, very properly, "may not ſome other trees ſerve to direct the farmer as to other ſeeds. The prudent gardener never ventures to put his houſe plants out, till the mulberry leaf is of a certain growth." Heſiod, continues this gentleman in his ingenious note on M. Barck's foliation of trees, began to fix the proper ſeaſons for plowing, ſowing, &c. by the appearance of birds of paſſage, or of inſects, or by the flowering of plants; but I do not find that this method was ever after attended to till Linnæus wrote. Heſiod ſays, that when the voice of the crane is heard over-head, then is the time for plowing; that if it ſhould happen to rain three days together when the cuckow ſings, late ſowing will then be as good as early ſowing; that when ſnails begin to creep out of their holes, and climb up the plants, it is time to leave off digging about vines, and take to pruning. There is a wonderful coincidence, which probably takes place in all countries, between vegetation and the arrival of certain birds of paſſage. Linnæus ſays, that the wood-anemone (in Sweden) blows from the arrival of the ſwallow: and Mr. Stillingfleet finds by a diary which he kept in Norfolk for the year 1755, that the ſwallow appeared there on the 6th of April, and the wood-anemone was in bloom on the 10th of the ſame month. Linnæus obſerves, that the marſh-marygold blows when the cuckow ſings; and Mr. Stillingfleet finds by his diary, that the marſh-marygold was in bloſſom on the 7th of April, and the cuckow ſung the ſame day.

A due temperature of the ſeaſon, with reſpect to heat or cold, drought or wet, for all theſe greatly influence the

ſtate

ſtate of the earth, is eſſentially neceſſary, and ſhould be carefully attended to by the huſbandman when he ſows: but the preciſe time moſt proper for this work, cannot, by any means, be invariably fixed, becauſe it will always depend on the concurrence of a variety of circumſtances. The ſeaſons are more or leſs forward, and the ground is more or leſs dry, in ſome years, than in others. A proper ſeries of well made obſervations would furniſh the beſt of rules in this reſpect, but certainly would not fix the time of ſowing to any particular day, or week, for years to come. Linnæus's method, of carefully obſerving the foliation of trees, &c. would determine the proper time for ſpring ſowing; and Pliny, after mentioning the ſeveral conſtellations by which farmers were guided in his time, inſtructs the huſbandman with regard to autumnal ſowing, upon a principle ſimilar to that of our great modern naturaliſt. "Why," ſays he, "does the huſbandman look up to the ſtars, of which he is ignorant, whilſt every hedge and tree point out the ſeaſon by the fall of their leaves? This circumſtance will indicate the temperature of the air in every climate, and ſhew whether the ſeaſon be early or late. This conſtitutes an univerſal rule for the whole world; becauſe trees ſhed their leaves in every country according to the difference of the ſeaſons. This gives a general ſignal for ſowing; náture declaring, that ſhe has then covered the earth againſt the inclemency of the winter, and enriched it with this manure."

I therefore can only ſay, in general, that it is better to ſow early in autumn, than too late, provided the ſeaſon will admit of it; becauſe the plants are better able to reſiſt the ſeverity of the winter, after they have acquired a certain degree of ſtrengh; and their roots being then longer, and conſequently better fixed in the earth, they will be leſs liable to be thrown out by froſt. For this reaſon, in particular, perhaps the colder the climate is, the earlier the wheat ſhould be ſowed. Some lands are of ſuch a nature, that they ſwell greatly in hard froſts, and, ſubſiding again upon a thaw, leave the roots of plants quite bare upon their ſurface. There have, indeed, been years in which fields ſowed very late, for inſtance in December, have done extremely well: but that ought not, on any account, to be made a rule; experience ſhewing that ſuch late ſowings very ſeldom anſwer. On the other hand, the corn is likewiſe expoſed to many dangers when ſowed too early: for the ſtalks which ſhoot up before winter cannot well bear hard froſt, though wheat would not be hurt by them when only in the blade.

M. de Chateauvieux, than whom we cannot have a better guide, is clearly of opinion, that, though the proper time of the year for ſowing be come, the corn ſhould not be put into the ground if the temperature of the ſeaſon be not favourable, and that on the contrary the ſowing of it ought to be deferred, in hopes of a change. "If, ſays he, the weather is very hot, and the earth extremely dry, it will be abſolutely neceſſary to wait till ſome rain has fallen; for otherwiſe the ſeed will riſe but very imperfectly. This I am ſure of, by which I contradict the common ſaying of ſome farmers, that the earth is the beſt granary to keep the corn in. Full of this notion, whenever the ſtated time comes round, they ſow without diſtinction, in wet land or in dry: even heat does not hinder them: they think their ſeed will certainly ſprout well after the firſt rain; but I have always experienced that the plants have come up thin.

"To ſatisfy myſelf ſtill farther in this point, I tried an experiment, purpoſely to know whether corn can be ſowed, with any reaſonable expectation of ſucceſs, when the weather is very hot, and the earth very dry. Upon reading Mr. Duhamel du Monceau's excellent Treatiſe on the Preſervation of Corn, I obſerved, that he had found by his experiments, that wheat dried in a ſtove heated to ſixty degrees of M. de Réaumur's thermometer, had loſt its faculty of growing. From thence I conjectured, that wheat which ſhould undergo a heat, for example, of thirty degrees during a longer time, would be equally parched up, and rendered incapable of vegetating. I conſidered the earth, when hot and dry, as a kind of ſtove, in which the ſeed, if it remain too long without receiving any moiſture, may become ſo dry, that the greateſt part of it will never be able to ſprout. This reaſoning is juſt, and I therefore determined to have recourſe to that truſty guide, experience.

"On the 18th of July, 1754, at four o'clock in the afternoon, I placed M. de Reaumur's thermometer two inches deep in the earth, and ſcreened it from the immediate impreſſion of the rays of the ſun. The liquor roſe to the thirty-firſt degree, which ſhewed me the heat of the earth.

"The thermometer being afterwards expoſed to the ſun, the liquor roſe to thirty-ſix degrees.

"The ſame day, I ſowed eighty grains of wheat in this ground. The heat continued near the ſame during the reſt of that month, and almoſt all Auguſt. On the 21ſt of July, only ten grains had ſhot up, and on the 16th of Auguſt there were in all ſixteen; after which, not one more roſe; conſequently ſixty-four grains out of the eighty never ſprouted at all.

"On the 28th of July I ſowed fifty grains. Only four of them roſe by the ſixteenth of Auguſt, and not one after. Here were again forty-ſix grains which did not grow at all.

"The ſame day, I ſowed ſixty grains in another place. On the ſixteenth of Auguſt only ſix grains had ſprouted, and not one plant more ever appeared after: conſequently here too were fifty-four grains which never grew. All theſe grains were ſowed in my garden, in exceeding good mould.

"I was ſure that the wheat which I ſowed was perfectly ſound, and in every reſpect capable of growing. It was therefore quite clear, that ſo a great number of grains out of the whole, which did not ſprout at all, had loſt the faculty of growing, by their being parched up by the heat and dryneſs of the earth. To be ſtill more certain of this, three weeks after I had ſowed theſe grains, I watered half of them ſeveral times; but to no purpoſe: not one of them roſe, and I found ſeveral of them quite whole in the earth where I had ſowed them.

"After this experiment, on the 11th of Auguſt I ſuſpended the ſowings I had begun on the 8th, and did not reſume them till the 26th, after ſome rain which fell on the 22d and 23d. Theſe laſt ſowings roſe much better than the firſt.

Upon the whole, M. de Chateauvieux concludes from his own repeated practice, that the beſt time for ſowing in ſuch a climate as Geneva (which differs very little from ours,) is, from the 20th of Auguſt to the end of September: and thinks that even the firſt fortnight in October may be taken in, if the land cannot poſſibly be ſowed ſooner. But he allows of this only in a caſe of neceſſity, and judges that, rather than ſow later, it is beſt to ſtay till ſpring.

"Thus, ſays he, it is that experience and obſervation teach us to leave off bad cuſtoms, or ſuch as are not found-

ed on principles with which a man of ſenſe may reſt ſatisfied.

It is of the greateſt conſequence to the farmers that every ſeed be placed in the earth at a proper depth, and in the beſt manner: but experiments are yet wanting to determine with due exactneſs, what is the depth which beſt ſuits each kind of grain, in different ſoils.

The method which Mr. Tull propoſes, is a very good and eaſy way to aſcertain this point for each particular ſowing. Take, ſays he, twelve ſticks, or gauges; bore a hole in one at the diſtance of half an inch from the end, in the ſecond at an inch, and ſo on, increaſing half an inch to each of the twelve. Drive a peg into each of theſe holes; then, in the ſame ſort of ground as you intend to plant, make a row of twenty holes with the half-inch gauge; put therein twenty good ſeeds; cover them up, and ſtick the gauge at the end of that row; then do the like with all the other eleven gauges. This will determine the depth at which moſt ſeeds will come up; and the drill, if that inſtrument be uſed for the ſowing, muſt be ſet accordingly.

Upon the the ſame principle, M. Duhamel dug a trench twelve feet long, ſloping it gradually from the ſurface at one end, to the depth of two feet at the other. He then ſowed different ſeeds in this trench, and, having put the earth into its former place, obſerved, 1. That hardly any ſeeds riſe when buried deeper than nine inches: 2. That ſome ſeeds riſe extremely well at the depth of ſix inches; and 3. That other ſeeds do not riſe at all when they are above one or two inches deep. Experience ſhews, that the ſame ſeeds may be ſowed deeper in a light, than in a heavy ſoil; that grains which lie too deep in the earth to ſpring up in a dry year, may riſe in a warm and moiſt ſeaſon; and that others which are buried ſtill deeper in the ground, will ſometimes remain there ſound and unaltered for ten or twenty years, at the end of which they will grow extremely well, and produce their proper plants, if they chance to be brought to the ſurface, by moving the earth, as was mentioned before.

The uſual way of ſowing in broad caſt cannot anſwer all the intentions of placing the ſeed properly in the earth, and muſt be attended with ſeveral inconveniences; ſuch as, the ſeed's becoming the prey of various birds and animals; its being laid ſo ſuperficially, that the ſun often parches it up, or a long continued rain, inſtead of promoting a kindly vegetation, ſoaks into the grains, and burſts them; the ſeed is very unequally ſowed, becauſe of the inequality of the handfuls which different ſowers graſp: and great part of it neceſſarily falls together into hollows, where the ſurface of the ground is at all unequal, &c.

Senſible of theſe diſadvantages, farmers have, eſpecially for their winter grain, adopted the method of ſowing under furrow, that is, ſowing one half of the ſeed in broad caſt, and then plowing it in, and afterwards ſowing the other half, which is covered by harrowing. But this method is alſo liable to almoſt as many objections as the other: for the quantity ſown in each particular ſpot, and the equal diſtribution which ought to take place throughout the whole, cannot but be even more uncertain than in the broad caſt, where the whole is ſowed at once; nor dares the farmer, in this ſowing under furrow, to omit ſowing the ſecond quantity, leſt great part of what has been plowed down be buried ſo deep that it cannot riſe, eſpecially if the ſoil is at all ſtrong.

Another general fault in the common ways of ſowing, is, that too much ſeed is employed; partly, becauſe cuſtom has eſtabliſhed a kind of rule in that reſpect, and partly on account of the allowance which it is neceſſary to make for what the birds eat, and for what lies too deep ever to riſe; circumſtances by which a very great quantity of corn is abſolutely loſt.

Theſe inconveniences are prevented by the drill, which 1. drops the ſeed at whatever depth and diſtance experience has ſhewn to be fitteſt for the particular kind which is ſowed; 2. fills all the furrows with earth, ſo that none of the grain remains uncovered; and 3. lets fall into each furrow the exact quantity of ſeed which has been found to be moſt proper. By this means every ſeed is ſo rightly placed in the earth, that we may be confident they will all do well, if they are not hurt by inſects. But as this inſtrument ſows only the abſolutely neceſſary quantity of ſeed, the huſbandman ought to be certain of the growth of every grain: becauſe it often happens, that part of the ſeed is imperfect and does not ſprout at all. As the eye cannot diſtinguiſh its quality, he ſhould aſſure himſelf of it, by previouſly ſowing fifty or an hundred grains taken by chance, but exactly counted: when theſe ſpring up, the number of plants will ſhew what proportion is deficient, and the quantity of the ſeed ſhould be increaſed accordingly. To know what ſpace ſhould be left between each ſeed thus planted in the ſurrow, for that ſpace ought to be different according to the nature of the plant, it will be neceſſary to obſerve how much ground a ſtrong and vigorous plant of the ſame kind takes up when arrived at its greateſt perfection, which it will moſt probably attain when cultivated according to the New Huſbandry; and the drill may then be ſet ſo as to drop each grain at a due diſtance.

Beſides leaving ſtated diſtances between each of the ſeeds which the drill depoſits in the furrow, a farther eſſential object in the New Huſbandry, is to leave proper ſpaces between the rows of corn, which, in this method, are ſowed with the greateſt regularity, nearer together, or farther aſunder, according to the nature of the plants intended to be cultivated. Some do beſt in ſingle rows, others in double, others again in triple rows, and others in quadruple; as will hereafter be more fully ſhewn by ſeveral experiments. *See the article* DRILL-PLOUGH.

SOW-THISTLE, a ſpecies of thiſtle common in cornfields and paſtures.

SPADE, a well known inſtrument uſed in digging.

SPANCEL, a rope to tye a cow's hinder legs.

SPATLING-POPPY. *See* CHICKWEED.

SPARSED-LEAVES, are thoſe which are placed irregularly about the ſeveral parts of a plant.

SPAVIN, a diſeaſe in horſes, being a ſwelling in or near ſome of the joints, and cauſes a lameneſs.

There are two kinds of ſpavins, called a blood-ſpavin, and a bog-ſpavin.

A blood-ſpavin is a ſwelling and dilatation of the vein that runs along the inſide of the hock, forming a little ſoft ſwelling in the hollow part, and is often attended with a weakneſs and lameneſs of the hock.

The cure ſhould be firſt attempted with reſtringents and bandage, which will contribute greatly to ſtrengthen all weakneſſes of the joints, and frequently will remove this diſorder, if early applied: but if, by theſe means the vein is not reduced to its uſual dimenſions, the ſkin ſhould be opened, and the vein tied with a crooked needle and

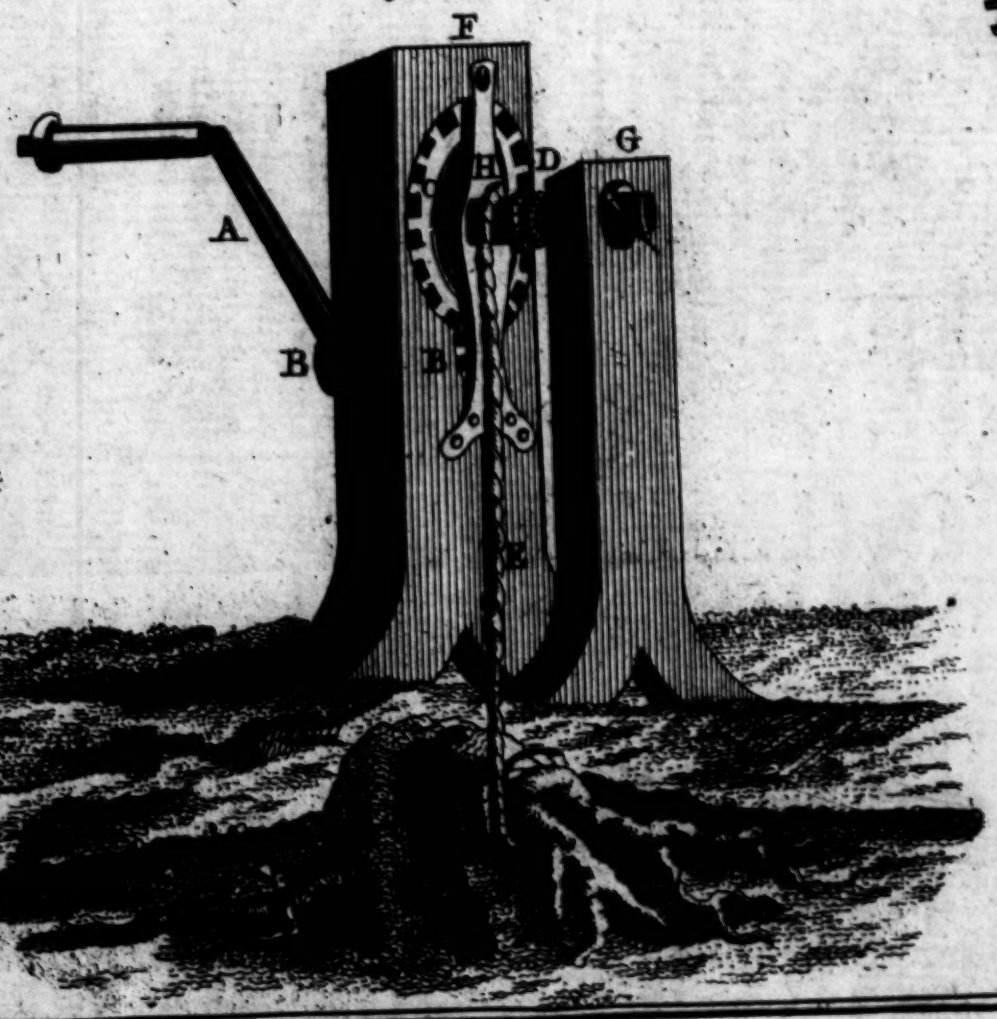

Fig. 3.

wax thread paſſed underneath it, both above and below the ſwelling, and the turgid part ſuffered to digeſt away with the ligatures: for this purpoſe, the wound may be daily dreſſed with turpentine, honey, and ſpirit of wine, incorporated together.

A bog ſpavin is an encyſted tumor on the inſide the hough, or, according to Dr. Bracken, a collection of browniſh gelatinous matter, contained in a bag, or cyſt, which he thinks to be the lubricating matter of the joint altered, the common membrane that incloſes it, forming the cyſt: this caſe he has taken the pains to illuſtrate in a young colt of his own, where he ſays, When the ſpavin was preſſed hard on the inſide the hough, there was a ſmall tumor on the outſide, which convinced him the fluid was withinſide the joint: he accordingly cut into it, diſcharged a large quantity of this gelatinous matter, dreſſed the ſore with doſils dipped in oil of turpentine, putting into it, once in three or four days, a powder made of calcined vitriol, allum, and bole: by this method of dreſſing, the bag ſloughed off, and came away, and the cure was ſucceſsfully compleated without any viſible ſcar.

This diſorder, according to the above deſcription, will ſcarcely ſubmit to any other method, except firing, when the cyſt ought to be penetrated to make it effectual; but in all obſtinate caſes that have reſiſted the above methods, both the cure of this, and the ſwellings called wind-galls ſhould, I think, be attempted in this manner. If, through the pain attending the operation or dreſſings, the joint ſhould ſwell and inflame, foment it twice a day, and apply a poultice over the dreſſings till it is reduced.

SPAYING, the operation of caſtrating the females of ſeveral kinds of animals, as ſows, bitches, &c. to prevent any farther conception, and promote their fattening.

It is performed by cutting them in the mid flank, on the left ſide, with a ſharp knife or lancet, taking out the uterus and cutting it off, and ſo ſtitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The uſual way is to make the inciſion aſlope two inches and a half long, that the fore finger may be put in towards the back to feel for the ovaries, which are two kernels as big as acorns on both ſides of the uterus, one of which is drawn to the wound, the ſtring thereof cut, and thus both taken out.

SPELT, the name of a ſpecies of grain, which though commonly reckoned a ſummer corn, is ſowed either in autumn, or in the ſpring, at the ſame time as wheat and rye. This grain, of which there are two ſorts, one with a ſingle, and the other with a double chaff, though both have always two ſeeds in each huſk, was formerly much eſteemed in Italy and Egypt, and is now very common in Germany, where they make of it bread, which is very nouriſhing and well taſted, but hard to digeſt. They likewiſe brew beer from it in ſome places. It was of this grain that the ancients made their frumenty, of which they were very fond. Though commonly ranked as a ſpecies of wheat, which it is not unlike when growing, its grain is ſmaller and of a blackiſh hue, its ſtalk thinner and leſs firm, and its ear flat and bearded, with ſeeds only on each ſide. Some writers diſtinguiſh a third ſort, by the name of white-rye, which they take to be the olyra of the Greeks and Latins; and ſeems to be what Mr. Mortimer calls taitico-ſpeltum, a ſort of naked barley, or wheat barley, cultivated in Staffordſhire, ſhaped like barley, but with a grain like wheat. It is much ſown at Rowley, Hamſtal, and Redmore, where they call it French barley. It makes good bread, and good malt, and yields a great increaſe; and therefore would do well to be tried in other places. It ripens early, does beſt in a dry ſoil, and is not apt to be much hurt by birds, from which its beard and double huſk preſerve it.

SPIKY-ROLLER, a very uſeful inſtrument in huſbandry, lately introduced by the ingenious Mr. Randall, of York, who has alſo obliged the world with the following account of it.

"I think, ſays Mr. Randall, it was in the ſpring of 1752, when I had fifty acres of ground, deſigned to be ſowed with barley, at one particular farm; but the weather had been ſo unfavourable, and the ſpring ſo extremely dry, that there was no ſuch thing as preparing the ground for the reception of the ſeed: and this was the caſe with the whole country, in theſe parts of England. On looking, one morning, at a barley roller, which laid juſt before me, I recollected, that Mr. Ellis, in one of his eight volumes in Huſbandry, made mention of a ſpiky roller, and referred the reader to another volume for its plate and deſcription, which were no-where to be found. I immediately ſent for ſome workmen, and produced this uſeful inſtrument againſt the next morning, as the ſeaſon was far ſpent, and much ground was to be ſowed, in ſeveral farms, with this grain.

"On this morning, a neighbouring, ſubſtantial farmer paſſed by us, with half the country for clotters, as we were going to put the horſes to the roller, as he had no longer patience to wait for rains, to reduce the rough ſtate of his ground, deſigned for barley-ſeed: he gazed at the roller, ſmiled, and went his way, with his troop. They, after clotting two acres, all returned the ſame way at night; their maſter rolled his eyes all over a field of about twenty acres, ſaw it perfectly fine (as the roller came back upon the ſame ground it went down), and, after a pauſe, ſaid, that was a good hedgehog, for doing ten times more in one day than all his troop together, and ten times finer, than a thouſand clotters could do, in the ſame time. This was the firſt time this farmer ever could be brought to ſay a civil thing of any uſeful inſtrument, though common ſenſe would pronounce the utility of this on his firſt ſeeing it; but the truth is, nothing but ſuch glaring effects can ever convince theſe people, as they have the great art of deſpiſing what they do not underſtand, or have not had in practice for ten centuries.

"While the ſame man was going over the other ground that ſtood in equal need of the roller, the ploughs were ſet on to turn up the ground he had rolled; and, when all was thus ploughed, the roller went again over the whole, to cruſh the clots, thus turned up, and made all as fine as before, by going twice in a place: then they ploughed for a ſeed furrow, ſowed the ſeed in the uſual way, and harrowed it in; then the roller, with a thorn buſh faſtened behind, went over again, once in a place, and left all exceeding fine, which even would not have diſgraced a gardener in his manner of preparing the ground for the garden culture in general.

"The conſequence of this lucky hit was, that, before the country could get their ſeed into the ground, my barley was fairly up, went forwards, and did extremely well; while, in general, my neighbour's barley made but a ſorry appearance, ariſing from the rough ſtate of the ground, which they could not bring into that fine order this grain requires, notwithſtanding all their toil and expence. This atchievement of the ſpiky roller eſtabliſhed its reputation, among

among the neighbouring farmers; but ſtill they could not prevail on themſelves to be at the expence, which indeed was not ſmall, in having one made for their own uſe. The reſult of all was, that I had other rollers made for the ground in other parts belonging to me, only they were made heavier, and both longer and larger, the better to ſuit the ſoils that were much ſtiffer.

"From this time we never ſowed any ſeed in the common form, but the ſpiky roller, and thorn buſh at its tail, followed the harrows; as it effectually buried the ſeed, and left the ground in a fine ſtate. It may eaſily be conceived, that this operation is of conſequence to vegetation: for the fine mould, being thus ſwept into the holes made by the irons, and where the ſeed was buried, muſt needs greatly promote their growing ſoon, and nouriſh them well above-ground; as it is well known, the finer the mould is, where the ſeed is depoſited, there vegetables are puſhed on to their deſtined maturity, if all other requiſites concur. And upon this principle it is, that if the corn in the ſpring is rolled once in a place in like manner, the owner will be far from having any cauſe to complain of the practice, provided the weather, and ſtate of the ground, will or ought to bear the tread of the horſes, and weight of the ſpiky roller.

"I am very ſenſible this will appear ſtrange to many perſons, as it looks like ſending a herd of rapacious wolves to nouriſh a flock of tender lambs, or tearing, bruiſing, and throwing all the corn up from their very roots, and bringing on a general deſolation over all the ground. This is like Siſyphus in Homer: we crop the ground with much ſweating and tugging, and then ſuffer all to be deſtroyed again, by this ponderous, grinning creature. But it may not, perhaps, be ill expreſſed, when we ſay, that, in order to come at the truth of things in farming, we muſt, according to the Greek epigram, aſcend downwards, and deſcend upward: the moſt triumphant ſucceſs, in the true bias of nature, in eſtabliſhing agriculture, riſes ſafely and ſurely on the foundation laid by bold experiments, that ſeem to contradict ſuperficial reaſon.

"Let us now conſider the effect of this terrible deſolator, as it goes over the young corn. If we conſider the ſyſtem of irons on the roller, they muſt leave ſome of the corn untouched by them, and then this is only rolling the corn in the common way, as it is only ſqueezed by the roller, and not bruiſed by the irons: ſo far there is no harm done. There muſt be corn, you will ſay, that is cruſhed and bruiſed, if not quite deſtroyed, by the violence of the irons: but ſuppoſing the corn loſt, whereever the irons pitch, which is very far from being the caſe; yet the untouched corn will be ſo improved, by this ſhattering and looſening of the ſoil about their roots, and ſcraping of the mould by the thorn buſh, and ſhaking and tearing the tender blade, that the owner will judge for himſelf, whether the Greek epigram ought to have a place among the paradoxes in agriculture. However, it can do no gentleman much harm to let the roller go down in one place, and up again in another, and give over; and this ſingle trial is all that the author pleads for, and that the weather and ſtate of the ground be ſuch, as will ſafely admit of the experiment.

"The uſe of the roller, in making the fallows, and preparing the ground to a requiſite degree of fineneſs, in the old, new, and what this Treatiſe calls the Semi-Virgilian Huſbandry, is, by this time, pretty evident to the reader, and needs no more inſtances, where ſuch perfection is deſired. We come now to ſpeak of its uſe on graſs-land, where the ſwarth is worn out by age, ſpoiled by moſs, or a bad ſort of graſs; or defective in any ſhape, from ſome cauſe or other, and yet it is very dangerous to plough it up, and lay it down better, on account of its ſituation, or it is not convenient perhaps for other reaſons, to diſturb it with the plough: whatever the caſe is, the owner, undoubtedly, would be exceeding glad to have a better burden of graſs on the ground, for the maintenance of his live ſtock, or for the pleaſure of ſeeing his ground, about his houſe, put in a better appearance.

"Here, then, there muſt be ſome compoſt prepared; that is, a mixture of the dunghill, ſods, aſhes, lime, mould, ſoap-aſhes, and ſuch like ingredients, or as many of them as can be conveniently procured, laid up in a heap, in this manner: a ſtratum of mould, about half a foot deep, then dung, then ſods, then ſoap-aſhes, then common aſhes, then lime, then dung; and to cover all with mould, about half a foot deep. When theſe have laid ſome time, that the dung may communicate its juice to the ſtrata beneath, the heap may be thrown down with ſpades, ſo as, in the operation, theſe ingredients, being mixed together, the firſt ſtratum, of half a foot, of the new heap, may be compoſed of all the ingredients; and ſo, in like manner, all the reſt of the ſtrata, till the new heap is compleated; and after theſe have laid ſome time, they will be very mellow, and fit for uſe the Michaelmas after the winter when the firſt heap was formed.

"We muſt now ſuppoſe the cloſe, whoſe ſwarth is to be improved, to have been laid down even, and not in ridges; and that between Michaelmas and Martinmas, the ſooner after the former the better, the ground is to be ſo moiſt, as to admit the irons of the ſpiky roller, but not the horſes feet; that is, the irons will penetrate three inches, or thereabouts, and the horſes feet make little or no impreſſion. Here, then, the roller muſt go up and down, till the ſwarth and ground are pretty well broken up: this being done, the ſeeds of clover, trefoil, and rye-graſs, or any other mixed with them, muſt be ſown, in the uſual way, and quantity: then the compoſt muſt be ſpread over the ſeed, ſo as to cover them, and a common barley roller, with a thorn buſh faſtened to it, muſt follow, and the ground ſhut up, leſt cattle ſhould do harm, by treading the ground. A gentleman, making this experiment, will have great cauſe to be pleaſed with what he has done; and will, alſo, ſee the neceſſity of laying down his ground as even as poſſible for the future, that he may increaſe the burden of his graſs, whenever it falls ſhort of a proper quantity, or quality." *Randall's Semi-Virgilian Huſbandry, Append. page* 1.

We have added the figure given of this uſeful inſtrument by the above ingenious gentleman, on Plate XXIV. Fig. 5.

A correſpondent of the editors of the Muſeum Ruſticum, who calls himſelf a clay farmer, has made the following obſervations on the ſtructure and utility of the ſpiky roller.

"Give me leave, ſays he, to communicate to my brother farmers, a moſt uſeful implement in huſbandry, which has but of late been introduced amongſt us. It is ſo very efficacious, and its powers ſo much ſuperior to all other inſtruments yet contrived for the reduction of ſtrong land, that, I think, there is not any poſſeſſor of ſuch ground (who has no objection to a fine ſeed furrow) that will be without this inſtrument. This laſt autumn it has been of the

the greateſt utility. For whilſt the neighbouring farmers were waiting for rain, ſo that they might with their own rolls and harrows bring their land to that degree of fineneſs they could wiſh to have their ſeed ſown in: thoſe who were poſſeſſed of the ſpiky roller, (for that is the name of the implement I am going to give ſome faint idea of, as it is impoſſible by letter to make any body more fully acquainted with it) had their fallows in ſuch a degree of fineneſs, as I never before ſaw that kind of land in; and had finiſhed the whole of their ſowing, before the others ever thought of taking their ploughs, &c. into the field.

"To begin then with the beſt deſcription I can give of the moſt complete I have yet ſeen. The roller is of oak, ſix feet three inches long, ſeventeen inches diameter, hooped with iron at each end; the circumference divided into eighteen equal parts, where rows of iron ſpikes are ſet (in the quincunx order) at ſix inches diſtance, one from the other, in the rows: ſo that there are thirteen ſpikes in one row, and twelve in every other throughout the circumference. The number of the ſpikes is two hundred and twenty-five. They are to project four inches and a half from the roller, and to be one inch by three quarters of an inch ſquare at that part of the ſpike next the roll, tapering off to three quarters of an inch by half an inch at the top part. The whole length of the ſpike, with what is driven into the wood, will be about nine inches long. And I would adviſe the falling ſide at the end of each ſpike to have a ſtroke or two with the hammer, that they may be a little more pointed to give them greater facility in penetrating the very hard clots they are deſigned to break. Every ſpike will weigh about one pound and a quarter, which will be of ſufficient ſtrength.

"The frame ſhould be made for horſes to draw a-breaſt, or with a pole for oxen. For by the horſes, &c. drawing double, the roll is more eaſily turned; and, beſides, it is likely to prevent the end of the roller from going over the driver, if by chance he ſhould fall. That it may with greater eaſe and conveniency be conveyed from field to field, or to any diſtance, an axis is fixed upon the frame immediately above the roll with wheels; ſo that by turning the frame, the wheels take up the roll, and away you may drive. And, when you have brought it to the field, in order to make uſe of it, by turning the frame back again, you let down the roll, and then the wheels are carried by the roller.

"Since making of the above deſcription, I have talked with the wheelwright, who tells me, he could greatly improve the manner of fixing the wheels, by making them run within the frame: for as they now run without, it ſets the wheels at ſuch a diſtance, as makes it difficult to paſs through gates made only the common width. And likewiſe ſays, that great care muſt be taken in fixing that part of the frame which the gudgeons of the rolls run in: for by that means the roll will be let down with greater eaſe; which will not be the caſe, if regard is not paid to that particular. The roller, frame, wheels, &c. are, together, about eleven hundred weight.

"If your land, by once paſſing over it with the roller, is not ſo fine as you could wiſh to have it, let a large harrow be faſtened to the frame of the roller, which will pull up the remaining clots, and thereby give the roller a better chance for breaking of them the ſecond time going over. Four able horſes are equal to this work." *Muſeum Ruſticum, vol.* V. *page* 372.

Theſe obſervations induced the inventor, Mr. Randall, to ſend the following letter to the editors of the Muſeum Ruſticum.

"In your Muſeum for laſt December, ſays he, I obſerve my name mentioned concerning the ſpiky roller. Without making any comment on the clay farmer's dimenſions, for conſtructing this implement of huſbandry, I beg leave to tell him, and the reſt of your readers, that the length of mine, which was the firſt I ever ſaw or heard of, except what the late Mr. Ellis mentioned to ſo little purpoſe, was ſeven feet, the diameters of the ends eighteen inches, and the whole cylinder made of the heart of oak: and when the irons were burnt in, and the man ſeated on the box deſigned for that purpoſe, the weight of the whole was about a ton. But you will think it ſtrange, that the blunt end of the irons were oppoſed to the clods, and run more taper, till they came to the ſurface of the cylinder, into which the irons were burnt, and inſerted about three inches: which was their length above the ſurface of the roller, and which, I always found, very ſufficient to cruſh the hardeſt clod that ever came in their way. Had I, indeed, attempted to go on the ground, when the ſoil was not perfectly dry, this poſition of the irons would have carried the clods round with the roller: for it is not its province to ſqueeze but cruſh. Nor indeed can a man do more harm to his ground, than going upon it, when it is not quite dry, with a roller, conſtructed according to the clay farmer's form and ſize of the irons; or by that which I have recommended. I am ſenſible thoſe who conſtruct the roller, according to the clay farmer's directions, imagine, that by inverting the ſhape, there is leſs danger of carrying the moiſt clods round with the roller: but, I muſt ſay again, there is no occaſion for this precaution: for, if the other form be at all neceſſary, it muſt be in the moiſt ſtate of the ground: which is the only reaſon, we ſhould keep the roller off the ſoil. I had the irons fixed in four inches aſunder, in the firſt row, from end to end. The ſecond row began juſt between the firſt and ſecond irons of the firſt row. The third row was like the firſt; and the fourth like the ſecond. Then alternately for the whole ſurface of the cylinder, as near as could be, the irons were four inches aſunder in each individual row, and four inches from row to row, as nearly as the ſurperficies of the cylinder would permit. I do not know how to convey a juſter idea to your readers of the ſhape of the irons, than to call them ox-harrow-teeth. For when I ſent for the workman, I deſired him to make ſo many of this denomination, ſix inches in length; and burn the ſmall end three inches into the wood: he went from me, as perfectly underſtanding what I meant; brought his number of irons; and inſerted them a proper depth into the cylinder. If ſome of your ſouth-country readers ſhould be at a loſs to know what is meant by ox-harrow teeth, they will be pleaſed to remember, that they are irons faſtened into two harrows, which are drawn by either four oxen and two horſes, or ſix oxen alone, in very ſtiff ſoils. Now, it will appear to you, that the roller itſelf, and one harrow, will require at leaſt four able horſes, according to the clay farmer's ſtating the caſe: but my roller, without harrows, always ſtood in need of three ſtout horſes, which the man, from his box, always drove a-breaſt, for the greater convenience of turning on the land's ends. But were I to have two ox-harrows, (which would only extend the length of the roller) following the roller, for the purpoſe of tearing up clods, in order

der

ther to be cruſhed, on going a ſecond time over the ſame, ſeven feet in length, I ſhould be obliged to have a much ſtronger team than four ſtout horſes; and, therefore, I muſt beg leave to obſerve, for this, an unanſwerable reaſon, that harrows are better omitted; as they always were, by my people, who ſet in with their ploughs, and turned up the ſoil from all requiſite depths, in order to have it cruſhed by the roller going twice in a place.

"If the clay farmer will not take it amiſs, I would tell him, that wheels to the roller only create expence and trouble. For I do not remember we ever had any diſadvantage from the weight of them in my four rollers, made for near a thouſand acres of land, of all denominations of ſoils, ſtiff and light: for, when the fellows had occaſion to convey the roller from one incloſure to another, and ſometimes over the hard high road, I never heard, or obſerved, there was the leaſt difficulty of doing it: as the irons were ſo ſtout, as not to receive any injury in the paſſage, otherwiſe than by friction; by which they would be indeed in time ſomewhat impaired. As to the width of the gates, I think there was never any ſtoppage; ſince the men, when they found the paſſage rather too ſtrait, could, by turning the horſes heads, eaſily incline the roller on one ſide, and by that means wriggle it in, where it was too long for entrance. Let who will be the father, or grandfather of this valuable inſtrument of huſbandry, I had reaſon to be extremely well pleaſed with my lucky hit, in conſtructing it from Mr. Ellis's barely mentioning a ſpiky roller: though, from his uſual giddineſs, he gave his readers no more than the name. As it is of conſequence to the world, to keep the expence of this inſtrument as low as poſſible, I ſhall be very ſorry to hear any more of wheels; for it may deter farmers from uſing it; and without their hearty concurrence, all will be only playing at farming. Gentlemen may pleaſe themſelves in every variation of the implements, and modes of culture: but without the aſſiſtance of thoſe, who bleſs the nation with their endleſs toil, a thouſand years hence will be as to-morrow.

"Beſides the purpoſes already mentioned, this roller muſt undoubtedly be of uſe in laying, originally, down lawns, or large pieces of graſs required to be level. Mr. Randal only mentions the reſtoring ſuch when depraved: but certainly this inſtrument muſt be extremely effectual in the caſe of all ſtiff lands, for the producing a good face in the firſt forming of fine pieces of graſs. The manner of doing this, in ſuch caſes, is too obvious to perſons qualified for executing ſuch work, to require any explanation: as the inſtrument may be uſed concurrently with any of the common methods of manuring and ſowing graſs ſeeds, as well as with Mr. Randal's compoſt, &c. they being no ways particularly neceſſary to the effects of the roller, though it may greatly aid them.

"This roller may likewiſe be very uſeful in preparing clay for the making canals or pieces of water. For where, as ſometimes happens, the clay grows dry, and will not admit of being duly tempered for uſe without great pains in breaking it, a very large quantity may very ſoon be reduced to the requiſite fineneſs, by ſpreading it on hard ground in a due thickneſs, and paſſing this roller a few times over it. In very great works, much trouble and labour may be ſometimes ſaved, by this means, where ſuch a roller is at hand; and the clay prepared in a manner that will anſwer the purpoſe much more effectually.

"It is certainly an inſtrument, which no farm, where the land is ſtiff, or in the leaſt liable to clot, ſhould want. For beſides the conſtant advantage of ſaving labour, and bringing land to a better condition for any kind of ſowing than the plough and harrow with any aſſiſtance of the work of hands can make it, in favourable ſeaſons and under ſuch circumſtances as Mr. Randal has mentioned in the above quotation, the loſs of the whole crop by an otherwiſe unavoidable delay beyond the ſeed time, may be with certainty prevented."

We ſhall conclude this article with the following ingenious account of the uſes of this inſtrument, which we have been favoured with from Mr. John Berington, of Winſley, near Hereford.

"As I live, ſays he, in a clay country, and had been often put to a great deal of difficulty in a dry unkind ſeaſon, in reducing the land to a proper tilth, I reſolved to make trial of Mr. Randal's ſpiky roller; but apprehending great ſtreſs muſt lie upon the horſe and frame, in turning ſuch, as well as tearing up the ground, it occurred to me, that I had ſeen recommended a double roller, that is, one divided in two parts. It is very probable that you have it already in deſign; if not, the following directions I imagine may ſuffice.

"Let the ends of each part be bound with narrow but ſtrong bands of iron, and let the ſpikes at the ends be placed cloſe to them; let each part have a ſeparate frame, but let the cheeks in which the inward gudgeons turn, be made of iron plates, about two inches wide above, and four where the gudgeons enter; the thickneſs, a common flat bar of iron; and theſe fixed, in any firm manner, to two cheeks of wood reaching down juſt to the bands, and of ſuch a thickneſs at bottom as not to interrupt the ſpikes. Let the inward gudgeons be made with quite flat heads, to prevent their ſlipping out in working; and this brings the two ends of the roller near together, which is of ſome little conſequence, as the fewer clots will be miſſed in working.

"Let the frames be joined together by four eyes, like thoſe of a ſmall gate, two at one end about five or ſix inches apart; the two at the end of the other, to take place juſt within them; an iron pin through all four, and keyed. Let the trills be placed juſt on the middle of each frame, and a bar of wood juſt behind the horſe to ſtrengthen them; the bar ſawed through in the middle, and joined by a ſtrong flat hinge; one ſide made to haſp upon a ſtaple, kept down with a wooden clet. This gives the whole proper play in working; and I may venture to affirm, it will be found, next to the plough, the moſt uſeful inſtrument in tillage, not only in reducing a ſtiff ſoil, but with a buſh at its tail, as Mr. Randal expreſſes it, will cover the ſeed when ſown much more effectually, and in a better manner, than a harrow, as it turns up the earth light and fine behind it; and though ſeemingly unwieldy, will turn with eaſe, and may be worked with one, two, or three horſes at moſt, upon any land that is of a proper dryneſs to work upon, of which I cannot well forbear giving you an inſtance: the carter that was to drive it exclaimed, when he firſt ſaw it, that it would kill all his horſes: ſome time after, as he was uſing it upon a piece of fallow, a fellow-ſervant wanted a horſe for ſome uſe, and was going to catch one; the carter called to him, and told him, he might take one of his, having three, as he could do very well with two. Now I believe

you

you will allow, that if it could ſo eaſily overcome the obſtinacy of a clown, there are very few clods that will be too hard for it.

" The ſpikes are about four inches without, and three within the wood; the thickneſs of the roller, and number of ſpikes, I think, may be determined, in ſome meaſure, by the nature of the ſoil it is to work upon."

SPINDLING, running to ſeed.

SPLENT, a hard excreſſence growing on the ſhank bone of a horſe.

Some horſes are more ſubject to ſplents than others; but young horſes are moſt liable to theſe infirmities, which often wear off, and diſappear of themſelves. Few horſes put out ſplents after they are ſeven or eight years old, unleſs they meet with blows or accidents.

A ſplent that ariſes in the middle of the ſhank bone is no ways dangerous; but thoſe that ariſe on the back part of this bone, when they grow large and preſs againſt the back ſinew, always cauſe lameneſs or ſtiffneſs, by rubbing againſt it; the others, except they are ſituated near the joints, ſeldom occaſion lameneſs.

As to the cure of ſplents, the beſt way is not to meddle with them, unleſs they are ſo large as to diſfigure a horſe, or ſo ſituated as to endanger his going lame.

Splents in their infancy, and on their firſt appearance, ſhould be well bathed with vinegar, or old verjuice; which, by ſtrengthening the fibres, often put a ſtop to their growth; for the membrane covering the bone, and not the bone itſelf, is here thickened; and in ſome conſtitutions purging, and afterwards diuretic drinks, will be a great means to remove the humidity and moiſture about the limbs, which is, what often gives riſe to ſuch excreſſences.

Various are the remedies preſcribed for this diſorder; the uſual way is to rub the ſplent with a round ſtick, or the handle of a hammer, till it is almoſt raw, and then touch it with oil of origanum. Others lay on a pitch plaiſter, with a little ſublimate, or arſenic, to deſtroy the ſubſtance: ſome uſe oil of vitriol; ſome tincture of cantharides; all which methods have at times ſucceeded; only they are apt to leave a ſcar with the loſs of hair. Thoſe applications that are of a more cauſtic nature often do more hurt than good, eſpecially when the ſplent is grown very hard, as they produce a rottenneſs, which keeps running ſeveral months before the ulcer can be healed, and then leaves an ugly ſcar.

Mild bliſters often repeated, as recommended in the article ſpavin, ſhould firſt be tried as the moſt eligible method, and will generally ſucceed, even beyond expectation: but if they fail, and the ſplent be near the knee or joints, you muſt fire and bliſter in the ſame manner as for the bone-ſpavin.

Splents on the back part of the ſhank-bone, are difficult to cure, by reaſon of the back ſinews covering them; the beſt way is to bore the ſplent in ſeveral places with an iron not very hot; and then to fire in the common way, not making the lines too deep, but very cloſe together.

To SPRAIN SEEDS, ſignifies, to throw them with a ſingle motion of the hand at a certain diſtance from one another.

SPRIG, a ſmall branch, a ſpray.

SPRING, the ſeaſon in which plants vegetate.

Spring alſo ſignifies a fountain, or iſſue of water from the earth. *See the articles* DRAINING, *and* WATER.

SPRING-WHEAT, a ſpecies of wheat ſown in the ſpring. *See the article* WHEAT.

The following experiment and obſervations on the comparative ripening of ſpring and common wheat made by the ingenious Mr. John Wynne Baker, and reported by that gentleman to the Dublin Society, muſt not be omitted here.

" Some little time after receiving the inſtructions I was honoured with from the ſociety, I was deſired by the committee, then ſitting, to ſettle the premiums for the ſucceeding year, to make a comparative experiment between ſpring and common wheat.

" The purpoſe of this experiment was to diſcover, whether common wheat would not ripen when ſown late in the ſpring, as well as ſpring wheat.

" Accordingly, on the twenty-eighth day of March, I ſowed two perches of each ſort of wheat in my garden, in drills three feet aſunder, at the rate of five ſtone to an acre. I had but two pounds of ſpring wheat, otherwiſe I ſhould have extended the experiment.

" The common wheat came up well, but the ſpring wheat came up very thin in the drills, which, for ſome time, I apprehended, was owing to ſome fault in the ſeed; but the caſe was otherwiſe, as appeared afterwards from a ſecond ſowing in another place: add to this, that in a few days I diſcovered mice had eaten great part of the ſeed; however, ſome little of it eſcaped, and planted greatly, as did the common wheat.

" As a ſubſtitute for the horſe-hoe, which could not be introduced in theſe ſmall experiments, I uſed the ſpade, and the plants grew to admiration.

" The fatality, which attends all ſmall experiments in the corn tribe, followed theſe: for I was obliged to cut the ſpring wheat before it was ripe, the birds, in defiance of all protection, having devoured moſt of it; however, it would have ripened completely, and, as a proof of this aſſertion, I have a few ears, which I ſelected from the reſt, which are very fine.

" It may be proper to obſerve, that the ſpring wheat was more expoſed to the ravages of birds than the other, as the common wheat I ſowed was bearded, which is always a great, though not a perfect, protection to it from birds.

" The common wheat met with a diſtemper which was quite as fatal to it, as the mice and birds were to the other: this was the ruſt, or mildew. Before this diſeaſe came upon it, it was as fine corn as ever I ſaw, but it never ripened; although in appearance the ears were very fine.

" This diſeaſe attacking this corn and ſparing the other, I am inclined to attribute to this circumſtance, viz. that this was very thick and ſtrong; whereas the other was very thin, from the accident before-mentioned: perhaps, had it been as thick, it might have ſhared the ſame fate. So that I think theſe experiments are not by any means concluſive, as to the ripening of either of theſe ſpecies of wheat, when ſown late in the ſpring.

" I ſowed another plot of ground, as was before mentioned, on the fourth of May with ſpring wheat, which came up well, grew very ſtrong, and formed very fine ears in appearance, but never ripened.

" On the twenty-ninth of April, I ſowed an acre of very good ground with common wheat, which I ſteeped before-hand in putrid water; it came up in eight days, but

made no figure till June; it formed ſmall ears, but produced no grain at all.

"So far we have two concluſive experiments that ſpring wheat will not ripen when ſown in the beginning of May; and that common wheat will not ripen when ſown the latter end of April.

"Notwithſtanding that our queſtion is not anſwered by the two firſt experiments; yet the diſeaſe attending the common wheat has furniſhed ſome obſervations with reſpect to the mildew, or ruſt, upon corn and other plants, which tend principally to confirm thoſe made by the ingenious Mr. Tillet, director of the mint at Troys, and ſeem to contradict moſt of our Engliſh writers on this diſeaſe; many of whom ſeem to have implicitly followed others, who, I am afraid, have undertaken to account for, and furniſh remedies againſt, a diſeaſe, which perhaps they had never ſeen.

"Various are the opinions, and many of them contradictory in themſelves: but, upon the whole, candour obliges me to own myſelf as much at a loſs to determine with certainty the cauſe of this diſeaſe, as, I find, the many writers are, who have thought themſelves perfect maſters of it. Even by reading ſix pompous pages, which I have gone over many times, I ſhould ſcarcely know the diſeaſe, ſo faint is the deſcription; but it will ever be known by the greateſt ſtrangers to country affairs under the French name, which indeed is as truly deſcriptive as it is laconic, by them it is called *rouille*, or ruſt. By the Romans it ſeems to have been called *rubigo*.

"I ſhall omit to give my obſervations upon this diſeaſe at preſent, as it would oblige me to quote many tedious paſſages, from the books; and where there is a contrariety of opinions, although without evidence: yet, a little man, with a few facts only to ſupport a new theory, would ſtand a chance of making but a poor figure.

"At preſent I join in opinion with Mr. Tillet, and Mr. Reneaume; who ſeem to think that the extravaſated juices of the plants, operated upon, and condenſed, by the acrimony of the air, I ſhould rather ſay incruſted, are the occaſion of it. To this I ſhall only add, that I am at preſent of opinion, that the lacerated parts of the plants giving paſſage to, or rather changing the courſe of, the juices before-mentioned (which are the nutriment and life of the plants) to the diminution, and loſs, of the vegetable food to the nobler parts, is the true cauſe of the plants failing in their produce: but, I repeat it, I attempt not here to account how, and from what cauſe, thoſe lacerations, which I believe to be the baſis of the diſeaſe, happen.

"The comparative experiment between ſpring and common wheat, I think, ſhould be repeated, as the diſcovery thereby ſought for tends to a public benefit: but it ſhould be in a larger way, and in an open expoſure.

"A circumſtance has recurred to my memory, which had eſcaped my attention from the time it happened, till ſince I entered upon this ſubject.

"Laſt ſpring a poor neighbour of mine told me he had loſt the ſeaſon for ſowing his wheat, for want of money to buy ſeed, but that, if he could get a barrel of Poland wheat, (as he called it) which was the white cone, he would then ſow his ground: accordingly he obtained the ſeed, and did ſow it; but I underſtand, upon enquiry, that it produced not a good crop. He ſowed it ſome time about the beginning of February.

"And yet I am informed there is a gentleman in Scotland, who makes it his conſtant practice to ſow his wheat in the ſpring by choice: and that he intends to publiſh a recommendation of that practice.

"The lateſt I ever ſowed any with ſucceſs was the 30th of December; but that was only a ſmall experiment."

SPROUT-HILL. *See the article* ANT-HILL.

SPRIT, a ſhoot or ſprout.

SPUR, a diſtemper which frequently attacks rye, and ſometimes does damage likewiſe to wheat. The following remarks will give an idea of it.

"1. The grains which have the ſpur are thicker and longer than the ſound ones, and generally project beyond their huſks, appearing ſometimes ſtrait and ſometimes more or leſs crooked.

"2. Their outſides are brown or black; their ſurface is rough; and one may frequently perceive in them three furrows, which run from end to end. Their outward end is always thicker than that which ſticks to the chaff, and that moſt ſwollen end is ſometimes ſplit into two or three parts. It is not unuſual to find on their ſurface cavities which ſeem to have been made by inſects.

"3. When a ſpurred grain is broken, one perceives in the middle or centre of it a pretty white flour, covered with another flour, which is rediſh or brown. Though this vitiated flour has ſome conſiſtency, it may nevertheleſs be crumbled between one's fingers. M. Aimen has indeed ſometimes found this powder almoſt as black as that of ſmutty wheat.

"4. Theſe grains, when put into water, ſwim at firſt, and afterwards ſink to the bottom. If chewed, they leave a bitter reliſh on the tongue.

"5. The chaff appears ſound, though what is outmoſt is ſomewhat browner than when the ears are ſound.

"6. All the grains of the ſame ear are not ever attacked with the ſpur.

"7. The grains which have this diſtemper ſtick leſs to the ſtalks than ſound grains do.

"8. M. Aimen imputes this diſtemper to the grains not being impregnated; and aſſures us that he has not ever found a germe in grains which had the ſpur. The ſame obſerver has collected, in a memoir which he has ſent me, ſeveral reflections and microſcopical obſervations; but I paſs over in ſilence ſuch reſearches as are more curious than uſeful.

"9. I ſhall not ſtop to refute the opinion of thoſe who have pretended that fogs, dews, rain, the moiſture of the earth, may give this diſtemper to rye. But I cannot help ſaying that M. Tillet thinks, as does alſo M. Aimen, that other plants, beſides rye, are ſubject to the ſpur. M. Tillet has ſeen, and M. Delu has ſhewn me, grains of wheat which had the ſpur. The ſpur ought therefore not to be confounded with the uſtilago or burnt grain: they are two different diſtempers: and what ſeems ſtill more to eſtabliſh this difference, is, that M. Tillet's experiments prove that the powder of the ſpurred grains is not contagious like that of the carious or burnt.

"M. Tillet is ſtrongly inclined to think that the ſpur is occaſioned by the ſting or bite of an inſect, which turns the rye into a kind of gall; and he ſuſpects a ſmall caterpillar of being the cauſe of this miſchief. But neither he nor I dare to ſpeak affirmatively on this point.

"Dodard, Longius, Fagon, Delahire, Noel, and, lately, M. Salerne, give particular accounts of the diſeaſes with which numbers of people have been ſeized in ſome years,

years, owing to their having lived upon bread in which there was much rye affected with this diſtemper.

"As moſt of the diſtempered grains are much bigger than the ſound ones, it is eaſy to ſeparate the greateſt part of them by ſifting. It is what the peaſants of Sologne do, when corn is not dear; but in times of great ſcarcity or dearth, they are loth to loſe ſo much grain: and then it is that they are attacked with a dry gangrene, which mortifies the extreme parts of the body, ſo that they fall off, almoſt without cauſing any pain, and without any hemorrhage. The Hotel-Dieu at Orleans had had many of theſe miſerable objects, who had not any thing more remaining than the bare trunk of the body, and yet lived in that condition ſeveral days.

"As it is not in every year that the ſpur in rye produces theſe dreadful accidents, Langius is of opinion that there may be two kinds of this diſtemper; one which is not hurtful, and the other which occaſions the gangrene we have been ſpeaking of. It is however probable that there is but one kind of ſpur, and that it does not hurt, firſt, when ſufficient care is taken in ſifting the grain; and, ſecondly, when only a ſmall part of the corn is diſtempered. It is alſo ſaid, that the ſpur loſes its bad quality after the grain has been kept a certain time: in which caſe, the reaſon why ſome peaſants are attacked with the gangrene in years of dearth may be, that they conſume their crop as ſoon as the harveſt is over." *Duhamel's Culture des Terres.*

SPURRE-WAY, a horſe-way through incloſed lands, and free to any one to ride in by right of cuſtom.

SPURREY, the name of a weed common in many parts of England. It ſeldom riſes above ſix inches in height, flowers in the beginning of July, ripens its ſeeds in Auguſt, and is an annual plant.

The beſt method of exterminating this weed is by ſummer fallows, and cutting it down before it can ſcatter its ſeeds, which are very ſmall.

They cultivate two ſpecies of this plant in Holland and Flanders for the winter food of cattle, when there is a ſcarcity of graſs. It is ſaid to enrich the milk of cows ſo as to make it afford excellent butter; and the mutton fed on it is preferable to that fed on turnips. Hens alſo eat this plant greedily, and it is commonly thought to make them lay an extraordinary number of eggs.

Though this plant cannot, from the lowneſs of its growth, afford a very great quantity of fodder, yet as it will grow on the pooreſt land, where no other graſs will thrive ſo well, it may be cultivated to conſiderable advantage in many places; and by feeding it off the ground, the dung of the cattle will improve the land.

The farmers in the low-countries commonly ſow it twice a year; the firſt time in April or May, to be in flower in June or July; and the ſecond time after their rye-harveſt, to ſerve their cattle in November and December. The uſual allowance with them is about twelve pounds of ſeed to an acre.

STABBING *of cattle. See the article* HOVEN.

STABLE, a place or houſe for horſes, &c. furniſhed with ſtalls and proper apartments to contain their food, &c.

Nothing conduces more to the health of a horſe than the having a good and wholeſome ſtable. The ſituation of a ſtable ſhould always be in a good air, and on a firm, dry, and hard ground, that in winter the horſe may go out and come in clean. It ſhould always be built ſomewhat on an aſcent, that the urine and other foulneſſes may be eaſily conveyed away by means of trenches or ſinks for that purpoſe. As there is no animal that delights more in cleanlineſs than the horſe, or that more abominates bad ſmells, care ſhould be taken that there be no hen-rooſt, hog-ſtie, or neceſſary-houſe, near the place where the ſtable is to be built; for the ſwallowing of feathers, which is very apt to happen, when hen-rooſts are near, often proves mortal to horſes; and the ſteams of a bog-houſe, or hog's-dung, will breed many diſtempers. The walls of a ſtable, which ought to be of brick rather than ſtone, ſhould be made of a moderate thickneſs, two bricks, or a brick and a half at leaſt, for the ſake of warmth in the winter, and to keep out the heat in the ſummer. The windows ſhould be made on the eaſt and north ſide of the building, that the north wind may be let in to cool the ſtables in the ſummer, and the riſing ſun all the year round, eſpecially in winter. The windows ſhould either be faſhed, or have large caſements, for the ſake of letting in air enough; and there ſhould always be cloſe wooden ſhutters, that the light may be ſhut out at pleaſure, by which means the horſe may be made to ſleep in the day as well as in the night, when it is judged proper he ſhould do ſo. Many pave the whole ſtable with ſtone, but that part which the horſe is to lie on ſhould be boarded with oak planks, which ſhould be laid as even as poſſible, and croſs-wiſe rather than length-wiſe; and there ſhould be ſeveral holes bored through them to receive the urine, and carry it off underneath the floor into one common receptacle; the ground behind ſhould be raiſed to a level with the planks, and it ſhould be paved with ſmall pebbles. There are two rings to be placed on each ſide of the ſtall, for the horſe's halter to run through, and a logger is to be fixed to the end of this ſufficient to poiſe it perpendicularly, but not ſo heavy as to tire the horſe, or to hinder him from eating; the beſt place for him to eat his corn in is a drawer or locker, made in the wainſcot partition, which need not be large, ſo that it may be taken out at pleaſure to clean it, by which means the common dirtineſs of a fixed manger may be avoided. Many people are againſt having a rack in their ſtables; they give the horſe his hay ſprinkled upon his litter, and if they think he treads it too much, they only nail up three or four boards, by way of a trough, to give it to him in: the reaſon of this is, that the continual lifting up of the head to feed out of the rack, is an unnatural poſture for a horſe, who was intended to take his food up from the ground, and makes him, as they expreſs it, withy-cragged. When there is ſtable-room enough, partitions are to be made for ſeveral horſes to ſtand in: theſe ſhould always allow room ſufficient for the horſe to turn about and lie down conveniently, and they ſhould be boarded up ſo high towards the head, that the horſes placed in ſeparate ſtalls may not be able to ſmell at one another, nor moleſt each other any way. One of theſe ſtalls ought to be covered in, and made convenient for the groom to lie in, in caſe of a match, or the ſickneſs of a horſe. Behind the horſes there ſhould be a row of pegs, to hang up ſaddles, bridles, and other utenſils; and ſome ſhelves for the bruſhes, pots of ointment, &c. The other requiſites for a ſtable are a dung-yard, a pump, and a conduit.

STACK, a large quantity of corn, hay, ſtraw, &c. regularly piled up, and generally thatched to defend the contents from the weather.

It is very common, in order to preſerve corn in the ſtraw,

to make it up into ſtacks, by which means they often meet with very great loſſes by the dampneſs of the ground, which commonly rots and ſpoils it, ſometimes near a yard thick; and by rats and mice, and other vermin that breed in the ſtack, which eat and devour a great part thereof. To prevent both theſe inconveniencies, where timber is plentiful, they ſet four, or ſix, or more poſts into the ground, according to the bigneſs that they deſign the ſtack, granary, or barn that the corn is to be laid in: on theſe poſts they lay what is the ground-plats of other buildings, upon which they make a floor, or lay pieces acroſs to ſupport the ſtack: and if they make a barn or granary of it they, erect ſides and a roof upon it; but if only a ſtack, they cover it with thatch, and the poſts that ſupport it is, by ſome perſons, covered round with tin near the top, for about a foot or ſo in breadth, in order to prevent the mice and rats getting up. But as tin is apt to ruſt, and ſo to loſe its ſmoothneſs, it will not anſwer the deſign long; therefore the better to prevent their getting up, is to cover them with Dutch tile, which will always keep ſmooth. But in Hampſhire and other counties where they have plenty of ſtone, they make their ſupporters of two ſtones, which is the beſt way.

The lower ſtone is about three feet high, two feet wide at the bottom, and one at the top; over this they lay another ſtone, of about a yard ſquare: ſome make it of a round form, which is the beſt. This prevents not only the mice and rats from climbing up, but alſo the dampneſs of the ground: and this way you may keep corn as long as you will, without much inconvenience or loſs, except what it loſeth in the firſt year's ſhrinking, and loſs of weight, which is very inconſiderable. Only you muſt obſerve, that what corn you ſtack muſt be bound up in ſheaves, that ſo the ears of the corn may be turned inward, and the ſtraw-ends out, which will ſave the corn from pigeons, crows, and other fowls, and likewiſe from the rain that beats on the ſides. If your ſtack be of wheat, you may lay oats or other coarſe grain on the top of it, under the thatch, the greateſt danger of wet being from the top, if any of the thatch ſhould blow off. And if you ſuſpect any rats or mice have got into the ſtack, greaſe a ſtick and thruſt it into it; and if there be any, they will gnaw the ſtick. The chief inconvenience that attends this way of keeping of corn, is its bulkineſs, and the farmer's wanting of his ſtraw to make dung with, and the chaff to give his cattle, &c. *Mortimer's Huſbandry, vol.* II. *pag.* 141.

STACK *of Wood*, a pile of wood three feet long, as many broad, and twelve feet high.

STADLE, the bottom of a corn mow, or hay-ſtack. It alſo ſignifies a tree ſuffered to grow for coarſe and common uſes, as poſts or rails.

STAG-EVIL. *See the article* STAGGERS.

STAGGERS, a diſeaſe incident to horſes: a kind of apoplexy.

Farriers generally include all diſtempers of the head, under two general denominations, viz. ſtaggers, and convulſions, wherein they always ſuppoſe the head primarily affected. But in treating theſe diſorders, we ſhall diſtinguiſh between thoſe that are peculiar to the head, as having their ſource originally thence, and thoſe that are only concomitants of ſome other diſeaſe, where the head is affected ſecondarily by conſent of nerves, the ſource of this diſorder being in the ſtomach, bowels, &c. By this method we ſhall avoid many blunders, which would otherwiſe ariſe in practice, for want of knowing the true ſeat of the diſorder.

In an apoplexy a horſe drops down ſuddenly, without other ſenſe or motion than a working at his flanks.

The previous ſymptoms are drowſineſs, watry eyes, ſomewhat full and inflamed; a diſpoſition to reel, feebleneſs, a bad appetite; the head almoſt conſtantly hanging, or reſting on the manger; ſometimes with little or no fever, and ſcarce any alteration in the dung or urine: the horſe is ſometimes diſpoſed to rear up, and apt to fall back when handled about the head, which is often the caſe with young horſes, to which it does not prove ſuddenly mortal, but with proper help they may ſometimes recover. If the apoplexy proceeds from wounds, or blows on the head, or matter on the brain, beſides the above ſymptoms, the horſe will be frantick by fits, eſpecially after his feeds, ſo as to ſtart and fly at every thing. Theſe caſes ſeldom admit of a perfect recovery; and when horſes fall down ſuddenly, and work violently at their flanks, without any ability to riſe after a plentiful bleeding, they ſeldom recover.

All that can be done is to empty the veſſels as ſpeedily as poſſible, by ſtriking the veins in ſeveral parts at once, bleeding to four or five quarts, and to raiſe up the horſe's head and ſhoulders, ſupporting them with plenty of ſtraw. If he ſurvives the fit, cut ſeveral rowels; give him night and morning, glyſters prepared with a ſtrong decoction of ſenna and ſalt, or the purging glyſter; blow once a day up his noſtrils a dram of powder of aſarabacca, which will promote a great diſcharge, afterwards two or three aloetic purges ſhould be given; and to ſecure him from a relapſe, by attenuating and thinning his blood, give him an ounce of equal parts of antimony and crocus metallorum for a month; or which is preferable, the ſame quantity of cinnabar of antimony and gum guaiacum.

If the fit proceeds only from fullneſs of blood, high feeding, and want of ſufficient exerciſe, or a ſizy blood (which is often the caſe with young horſes, who though they reel, ſtagger, and ſometimes ſuddenly fall down, yet are eaſily cured by the above method) an opening diet with ſcalded bran and barley will be neceſſary for ſome time; and the bleeding may be repeated in ſmall quantities.

As to the other diſorders of the head, ſuch as lethargy, or ſleeping evil, epilepſy, or falling ſickneſs, vertigo, frenzy, and madneſs, convulſions, and paralytical diſorders, as they are moſt of them to be treated as the apoplexy and epilepſy, by bleeding and evacuations, with the alteratives there directed, we ſhall wave treating on them ſeparately, but mention ſome particular rules to diſtinguiſh them, according to the plan we laid down, and then offer ſome general remedies for the ſeveral purpoſes.

Thus in order to diſtinguiſh epileptic diſorders and convulſions (which are often occaſioned by worms, bots, and ulcerations of the ſtomach, bowels and midriff) from thoſe which ariſe from original cauſes in the head only, we ſhall deſcribe the ſymptoms which diſtinguiſh them from each other; by which means we ſhall be able to avoid any miſtake in the application of the remedy: and as epileptic diſorders have by ignorant farriers been miſtaken for the gripes, we ſhall alſo diſtinguiſh theſe diſorders by the ſymptoms.

In

In an epilepſy, or falling ſickneſs, the horſe reels and ſtaggers, his eyes are fixed in his head, he has no ſenſe of what he is doing, he ſtales and dungs inſenſibly, he runs round and falls ſuddenly; ſometimes he is immoveable, with his legs ſtretched out, as if he was dead, except only a quick motion of his heart and lungs, which cauſes a violent working of his flanks: ſometimes he has involuntary motions; and ſhaking of his limbs, ſo ſtrong, that he has not only beat and ſpurned his litter, but the pavement with it; and with theſe alternate ſymptoms a horſe has continued more than three hours, and then has as ſurprizingly recovered; at the going off of the fit, he generally foams at the mouth, the foam being white and dry, like what comes from a healthful horſe when he champs on the bit.

But in all kinds of gripes, whether they proceed from diſorders in the guts, or retention of urine, a horſe is often up and down, rolls and tumbles about, and when he goes to lie down generally makes ſeveral motions with great ſeeming carefulneſs, which ſhews he has a ſenſe of his pain, and if he lays ſtretched out for any time, it is generally but for a ſhort ſpace.

Epilepſies and convulſions may ariſe from blows on the head, too violent exerciſe, and hard ſtraining; and from a fullneſs of blood, or impoveriſhed blood, and ſurfeits; which are ſome of the cauſes that denote the original diſorder.

But the head may alſo be affected by ſympathy of nerves; for exceſſive pain in any part of the body will excite convulſions, eſpecially if the nerves and tendinous parts are affected, as by wounds, punctures, and bruiſes externally; and by ulcers, gatherings of matter, and by bots and worms, wounding and vellicating the nervous parts internally; long coſtiveneſs has ſometimes alſo occaſioned theſe diſorders. In all ſuch caſes, the original cauſe muſt principally be attended to.

In lethargic diſorders the horſe generally reſts his head with his mouth in the manger, and his pole often reclined to one ſide; he will ſhew an inclination to eat, but generally falls aſleep with his food in his mouth, and he frequently ſwallows it whole, without chewing: emollient glyſters are extremely neceſſary in this caſe, with the nervous balls recommended for the ſtaggers, and convulſions: ſtrong purges are not requiſite, nor muſt you bleed in too large quantities, unleſs the horſe be young and luſty. In old horſes rowels and large evacuations are improper, but volatiles of all kinds are of uſe, when they can be afforded; an alterative purge may be given and repeated on his amendment.

This diſtemper is to be cured by theſe means, if the horſe is not old and paſt his vigour. It is a good ſign if he has a tolerable appetite, and drinks freely without ſlabbering, and if he lies down, and riſes up carefully, though it be but ſeldom.

But if a lethargic horſe does not lie down, if he is altogether ſtupid and careleſs, and takes no notice of any thing that comes near him; if he dungs and ſtales ſeldom, and even while he ſleeps and dozes, it is a bad ſign: if he runs at the noſe thick white matter, it may relieve him, but if a viſcid gleet that ſticks to his noſtrils like glue, which increaſing, turns to a profuſe running of ropy, rediſh and greeniſh matter, it is an infallible ſign of great decay of nature; and that it will prove deadly.

Young horſes from four to ſix years, are very ſubject to convulſions, from bots in the ſpring; and the large coach-breed more than the ſaddle: they are ſeized without any previous notice, and if bots and worms are diſcovered in their dung, the cauſe ſeems to be out of doubt, more eſpecially if they have lately come out of a dealer's hands.

When this convulſion proceeds from a diſtemperature of the midriff, or any of the principal bowels, it is to be diſtinguiſhed from bots and vermin, by previous ſymptoms: the horſe falls off his ſtomach; and grows gradually weak, feeble, and diſpirited in his work; and turns ſhort-breathed with the leaſt exerciſe.

The lively deſcription of that univerſal cramp or convulſion, called by ſome the ſtag-evil, which ſeizes all the muſcles of the body at once, and locks up the jaws, ſo that it is impoſſible almoſt to force them open, we ſhall give in Mr. Gibſon's own words; who ſays, As ſoon as the horſe is ſeized, his head is raiſed with his noſe towards the rack, his ears pricked up, and his tail cocked, looking with eagerneſs as an hungry horſe when hay is put down to him, or like a high-ſpirited horſe when he is put upon his mettle; inſomuch that thoſe who are ſtrangers to ſuch things, when they ſee a horſe ſtand in this manner, will ſcarce believe any thing of conſequence ails him; but they are ſoon convinced, when they ſee other ſymptoms come on apace, and that his neck grows ſtiff, cramped, and almoſt immoveable; and if a horſe in this condition lives a few days, ſeveral knots will ariſe on the tendinous parts thereof, and all the muſcles both before and behind, will be ſo much pulled and cramped, and ſo ſtretched, that he looks as if he was nailed to the pavement, with his legs ſtiff, wide and ſtradling, his ſkin is drawn ſo tight on all parts of the body that it is almoſt impoſſible to move it; and if trial be made to make him walk, he is ready to fall at every ſtep, unleſs he be carefully ſupported; his eyes are ſo fixed with the inaction of the muſcles, as gives him a deadneſs in his looks; he ſnorts and ſneezes often, pants continually with ſhortneſs of breath: and this ſymptom increaſes continually till he drops down dead; which generally happens in a few days, unleſs ſome ſudden and very effectual turn can be given to the diſtemper.

In all theſe caſes the horſe ſhould firſt be bled plentifully, unleſs he is low in fleſh, old, or lately come off any hard continued duty, then you muſt be more ſparing of his blood; afterwards give the following ball:

> Take aſſa fœtida half an ounce; Ruſſia caſtor powdered, two drams; valerian root powdered, one ounce; make into a ball with honey and oil of amber.

This ball may be given twice a day at firſt; and then once, waſhed down with a decoction of miſletoe, or valerian, ſweetened with liquorice or honey: an ounce of aſſa fœtida may be tied up in a piece of ſtrong coarſe linnen rag, and put behind his grinders to champ on.

The laxative purges and emollient glyſters ſhould be given intermediately to keep the body open; but when the former balls have been taken a week or ten days, the following may be given once a day with the valerian decoction.

> Take cinnabar of antimony ſix drams, aſſa fœtida half an ounce, ariſtolochia, myrrh and bay berries, of each two drams: make into a ball with treacle and oil of amber.

This is the moſt effectual method of treating theſe diſorders; but when they are ſuſpected to ariſe from bots, and worms, which is generally the caſe, mercurial medic ines muſt lead the way. Thus,

Take mercurius dulcis, and philonium, of each half an ounce: make into a ball with conſerve of roſes, and give the horſe immediately; half the quantity may be repeated in four or five days.

The following infuſion ſhould then be given, to the quantity of three or four horns, three or four times a day, till the ſymptoms abate; when the above nervous balls may be continued till they are removed.

Take penny-royal and rue, of each two large handfuls; chamomile flowers one handful; aſſa fœtida and caſtor, of each half an ounce; ſaffron and liquorice root ſliced, of each two drams: infuſe in two quarts of boiling water; pour off from the ingredients as wanted.

If the caſtor is omitted, add an ounce of aſſa fœtida.

The following ointment may be rubbed into the cheeks, temples, neck, ſhoulders, ſpines, of the back and loins, and wherever there is the greateſt contractions and ſtiffneſs.

Take nerve and marſhmallow ointment, of each four ounces; oil of amber two ounces; with a ſufficient quantity of camphorate ſpirit of wine: make a liniment.

To horſes of ſmall value give the following:

Take rue, penny-royal, and tobacco, of each a handful; aſſa fœtida an ounce; boil in a quart of forge-water: let the decoction ſtand on the ingredients, and give as the former.

When the jaws are ſo locked up that medicines cannot be given by the mouth, it is more eligible then to give them by way of glyſter; for forcing open the jaws by violence, often puts a horſe into ſuch agonies, that the ſymptoms are thereby increaſed. The infuſion above may be given for this purpoſe, or the following.

Take rue, penny-royal, and chamomile flowers, of each a handful, valerian root two ounces, boil in five pints of water to two quarts; in the ſtrained liquor diſſolve caſtor and aſſa fœtida, of each half an ounce, or of aſſa fœtida alone one ounce, common oil four ounces. Give this glyſter once a day.

In this caſe alſo he muſt be ſupported by nouriſhing glyſters, made of milk pottage, broths, &c. which muſt be given to the quantity of three or four quarts a day; glyſters of this kind will be retained, and abſorbed into the blood; and there have been inſtances of horſes thus ſupported for three weeks together, who muſt otherwiſe have periſhed.

Mr. Gibſon mentions ſome extraordinary inſtances of ſucceſs in caſes of this ſort by theſe methods, and repeated frictions, which are extremely ſerviceable in all convulſive diſorders, and often prevent their being jaw-ſet; they ſhould be applied with unwearied diligence every two or three hours, wherever any ſtiffneſs or contractions on the muſcles appear, for a horſe in this condition never lies down till they are in ſome meaſure removed.

He takes particular notice of a horſe, whoſe jaws were ſo locked up for three weeks, that both food and medicine were forced to be given by glyſter; that not having recovered the uſe of his jaws for a fortnight, though he now moved them with leſs ſtiffneſs, he was determined, from the known relaxing power of opium, to give him half an ounce of it, diſſolved in one of his glyſters, the good effects of which were ſo evident, by a general amendment, that he was incouraged to continue it in the following manner.

Take Mathew's pill, and aſſa fœtida, of each an ounce: make into a ball.

This ball he gave for one doſe, and repeated once: and by this, and the uſe of the nervous medicines given twice a week, and gentle purging, the horſe was perfectly recovered.

The uſe of rowels in theſe caſes is generally unſucceſsful, the ſkin being ſo tenſe and tight, that they ſeldom digeſt kindly, and ſometimes mortify; ſo that if they are applied, they ſhould be put under the jaws, and in the breaſt.

The red hot iron ſo frequently run through the foretop and mane, near the occipital bone, for this purpoſe, has often been found to have deſtroyed the cervical ligament. *See the article* ROWEL. *Bartlet's Farriery, p.* 78.

Sheep are alſo ſubject to the ſtaggers, and the beſt remedy they find for it is, to drive them to change of grounds often, to keep the grounds from tainting.

"I obſerve, ſays Mr. Liſle, that thoſe lambs which die of the ſtaggers, do not die till they begin to eat graſs, and of thoſe the fineſt and luſtieſt; whence I conclude, that it is not the cold weather alone that brings the ſtaggers, but from their feeding on cold watery graſs in the months of March and April, which makes them abound in watery humours in the bodies, which the cold winds ſeize on and chill, and bring thoſe cramps and aches into their limbs. It is obſerved this diſeaſe is much prevented by the early folding of lambs, and with good reaſon, for thereby, in the cold nights, the lambs are kept warm, and alſo prevented from eating ſo much graſs as they otherwiſe would, whereby ſuch watery humours are fed. *Liſle's Huſbandry, vol.* II. *p.* 210.

STAGGERWORT. *See the article* RAGWORT.

STAKE, a piece of wood, or ſtrong ſtick fixed in the ground.

STALE, urine.

STALK, the ſtem, or ſtock of a plant.

STALL, a crib at which a horſe is fed, or where any horſe is kept in a ſtable.

STALL-FED, fed with dry ſeed, not with graſs.

STALLION, a ſtone horſe, deſigned for the covering of mares, in order to propagate the ſpecies. *See the article* HORSE.

STAMWOOD, the root of trees grubbed up.

STANDARDS, or *Standrels*, ſignify the young trees reſerved

reſerved at the felling of woods, for the growth of timber.

STANDARDS, alſo imply fruit-trees, intended to grow in an open expoſure, and not to be hacked and mangled with the knife, as the dwarf trees, and thoſe planted againſt walls are.

STANK, a dam, or bank to ſtop water.

STANNER-WORT. *See the article* RAG-WORT.

STAVERS. *See the article* STAGGERS.

STEE, a ladder.

STEM, that part of a plant ariſing from the root, and which ſuſtains the leaves, flowers, fruits, &c.

STEEPS, certain preparations for ſteeping of corn intended to be ſown. *See the article* SEED.

STELE, a ſtalk, a handle.

STEER, a young bullock.

STEG, a gander.

STERCORARY, a collection of dung properly ſecured from any injuries of the weather.

In collecting manures from time to time, as they come to hand, farmers generally keep them together in what they call dung-hills, where they remain expoſed to the heat of the ſun, the waſhing of rain, and drying winds: by which means all their virtue is drawn forth, and carried away. Mr. Evelyn juſtly cenſures this wrong practice, and at the ſame time gives the following directions for making a ſtercorary, to contain the compoſt collected by huſbandmen.

Dig a ſquare or oblong pit, of the ſize ſuited to the quantity of compoſt wanted, or proportioned to the extent of the ground intended to be manured. Let the ſide next the fields be made ſloping, ſo as to receive a cart to load or unload eaſily. Let the bottom be well paved, and both the ſides lined, unleſs it be made in a bed of clay or chalk, that it may be capable of retaining water like a ciſtern; for it is of great importance, as Columella obſerves, that the dung be well ſoaked in liquor, in order to deſtroy the vegetative faculty of the ſeeds of weeds which may chance to be mixed with it, or the litter. If channels, or gutters, can be directed to this pit, from the ſtables and offices about the houſe, they will be of great ſervice. Mr. Evelyn is of opinion that this ſtercorary ſhould be under cover, ſo as at leaſt to hinder downright rains from falling upon it:—but if care be taken to make the pit in a place where no running water, or ſprings can come to it; and if the farmer covers the dung, as it is collected, with a coat of mould, to prevent the ſun's exhaling, or the rain's waſhing away its richneſs; I cannot help thinking that the quantity of water which falls in rain, would not be more than is requiſite to moiſten the mixture, and bring on that putrid fermentation which is neceſſary for the due incorporating and perfecting of the compoſt. It will, however, be right to have a ſhade to put over it occaſionally, in caſe the ſeaſon ſhould prove extremely wet.—Columella informs us, that the Romans covered their ſtercoraries with hurdles; but does not ſpeak of covering them with mould, as here directed.

The pit being thus prepared, the farmer's next ſtudy ſhould be to fill it with a compoſt ſuited to the nature of his land. Thus, if his ſoil is a ſtrong clay, a layer of dung ſhould be covered with a layer of ſand, rubbiſh of old houſes, or other ſubſtances already mentioned for the improvement of clay. Litter of all kinds becomes a good addition, becauſe it is ſlow in decaying, and if mixed with the clay, keeps its parts aſunder. The compoſt for meliorating clay may be carried out, and mixed with the earth, freſher than for any other ſoil; becauſe, in this ſtate, it will more effectually keep the particles of the clay ſeparated; and if ſome degree of its putrefaction is carried on in the ſoil, it will much more powerfully open it.—If, on the contrary, the ſoil is ſand, the dung ſhould be mixed with clay, ſcouring of ponds, or other fat ſlimy ſubſtances, which may give conſiſtence to the ſand. And if the farmer is happy in a ſoil in which neither of the extremes prevail, he may then mix his manure with the richeſt mould he can find, and incorporate them well together, by frequent turning, before the compoſt is carried to the field.—Columella thinks they are ſlothful huſbandmen, who, in thirty days, have not a load of dung of twenty buſhels, from each of the leſſer cattle, and ten loads from each of the larger ſort, by means of judicious mixtures with their dung. He thinks this mixture, or compoſt, moſt beneficial to corn, after it is a year old; becauſe it ſtill retains all its ſtrength, and does not then breed weeds.

"Many good effects, ſays Dr. Home, particularly that of hindering the oils from being volatilized, and of fixing them, will ariſe from a mixture of lime with theſe compoſts, after they are thoroughly rotted. But as many experiments have proved that quick-lime powerfully reſiſts putrefaction, it does not ſeem judicious to mix it with dung-hills which are not ſufficiently putrefied, as it muſt ſtop that proceſs.

"There is a very great attraction betwixt quick-lime and all oily bodies. It unites intimately with expreſſed oils. With this intention it is uſed in the manufacture of ſoap, to help the junction of the alkaline ſalts and oils. It muſt, therefore, attract the oils powerfully from the air and earth, diſſolve them, and render them miſcible with water: it muſt, from this reaſon, ſoon exhauſt the ſoil of all its oleaginous particles, if the farmer does not take care to ſupply them by dung or animal ſubſtances. Farmers have, by experience, diſcovered it to be a great impoveriſher of lands; but they did not know how it acted. Its operation is, to exhauſt the earth of its oils. The proper cure for this is, to mix dung with the lime, ſo that it may have ſomething to act on.

"Lime is a great diſſolver of all bodies, both vegetable and animal; but particularly the latter. We know how ſoon it reduces hair and woollen rags into a pulpy ſubſtance. This effect is ſo ſtrong, that, in the common method of ſpeaking, it is ſaid to burn them. In this way it certainly operates in the earth, by diſſolving all animal and dry vegetable ſubſtances, and converting them to the nouriſhment of vegetables, at leaſt ſooner than otherwiſe they would be. Like other calcarious bodies, it is not diſſolvable but by acids. With theſe, a great effervеſcence happens, a ſolution of the calcarious body is made, and a neutral ſalt is formed from that conjunction. This neutral ſalt is always ſoluble in water, unleſs where the acid of vitriol is uſed." *Home's Principles of Vegetation, page* 69, 70.

The Society of Improvers in the Knowledge of Agriculture in Scotland, have paid great attention to the ſubject of compoſts, and are very particular in their inſtructions on this head, to ſeveral of their correſpondents. I gladly take this opportunity of paying the tribute of praiſe juſtly due to their public ſpirit, and congratulate them on the great ſucceſs which has attended their labours in many parts of their country. At the ſame time I cannot help regretting,

regretting, that, though all our neighbours have ſet us ſo many examples of periodical inſtruction in this moſt uſeful art, there is not yet any inſtitution of that kind in England. It is to be hoped, that the Society for the Encouragement of Arts, Manufactures and Commerce, will ſoon take off this reproach, and not ſuffer it to be longer ſaid that agriculture lies neglected in this kingdom, where the people enjoy every advantage requiſite to promote it, in a far higher degree than the inhabitants of any other country in the world. The wealth of our farmers is incomparably greater; their property, and the tenure of their lands, are infinitely better ſecured; and the happieſt of ſoils and climates combine to reward their labour.

The Society in Scotland give to a gentleman who had written to them, and who had clay and lime at command, the following judicious directions for collecting a compoſt, or making a ſtercorary, for the improvement of a ſandy ſoil. "Take, ſay they, in the field intended to be manured, a head-ridge, the moſt conveniently ſituated for a ſtercorary. Plow it two or three times, as deep as can be, in the cleaving way, if the ridge be high gathered, and harrow it well: then lay thereon your ſlimy clay, about a foot thick, leaving a part of the ground un-covered: next lay a thin layer of dung, another of clay, and after that a layer of un-ſlaked lime, at leaſt a foot thick: then throw up the earth left uncovered on each ſide. After this, repeat another layer of clay, and lime-ſtone, as before, and finiſh it with a layer of clay and ſea-wreck, covered with earth. The more of the ſlimy clay the better: for though it may be cold, yet it will not be the worſe for a ſandy hot ground. If you examine the clay, we doubt not but you will find it a very fat ſubſtance; being, as we conjecture, moſtly muſcle and other ſhells mixed with earth, brought by the tide and river Southeſque. On the coaſt of Lothian, we found that ſlimy ſubſtance to be nothing elſe; and if it be ſo with you, it is certainly one of the beſt manures."

"After this ſtercorary has ſtood ſix weeks or two months, incorporating and fermenting, turn and mix it; and that this work may be performed to the better purpoſe, and with as ſmall an expence as poſſible, yoke your plow, enter upon your ſtercorary with a cleaving furrow, and continue repeating the plowings the ſame way, until the very bottom of the ſtercorary be ripped up; then harrow it: it is impoſſible to over-do it. If it be very cloddy, it ſhould be harrowed between the plowings. Begin then in the middle, and plow again and again in the gathering way, until it be brought into as narrow bounds, and be raiſed as high as poſſible. Let all that the plow has left be gathered up, and thrown with ſhovels on the top. Every ſuch turning and heaping occaſions a new ferment, and improves the manure. If the ſeeds of barley, or of any other quick-growing vegetable, were ſprinkled thin on the ſtercorary, and the plants buried in it, when fulleſt of ſap, before they come to ſeed, by turning or more heaping, the manure would be improved." This might be repeated ſeveral times in the courſe of the ſeaſon; for the practice has been found ſucceſsful. *Maxwell's Collection, page* 26.

In another place, they obſerve that ſuch a ſtercorary may be turned in the ſame manner as ground is trenched. The higher it is raiſed, the better. Each turning will make it heat like a garden hot-bed, and this fermentation will reduce it to a fine fat mould. If the firſt heat ſhould go off (which may eaſily be known by thruſting a pole into it) before it has produced this effect, it may be turned over again, and will take a new heat, which is of great advantage to it, beſides the better mixing of the ſeveral manures. About fifty or ſixty cart-loads of this compoſt are uſed upon an acre of ground. I have been the more particular in extracting this account, becauſe any farmer, by attending to the rules here given, may ſuit his compoſt to the nature of his ſoil. Where the ſoil varies, he will do well to have another ſtercorary, properly compoſed, in a convenient part of the field he intends to manure.

The ſame ſociety, in their directions for the management of ſheeps dung, where the ſheep are houſed, or fed under cover during the inclemency of the winter, adviſe laying under them ſubſtances ſuited to the nature of the ſoil intended to be improved. A layer of ſand, for inſtance, for ſtiff land, will be greatly benefited by being covered with a couch of litter in the ſheep-houſe. When their dung becomes troubleſome or offenſive to them, or begins to make them dirty, the whole ſhould be removed to the ſtercorary. But if the dung of the ſheep is to be laid on a ſandy ſoil, clay, or any ſuch ſubſtance, though covered with litter, it would ſoon become wet, and too cold for the ſheep to lie on. It would therefore be better, in this caſe, to ſpread a thick couch of litter under the ſheep, and mix this in the ſtercorary with the lime, &c. by which means the ſame advantage may be obtained, without injury to the cattle. If loam, or a rich mould, be laid under ſheep, the judicious farmer will be careful to collect a ſufficient quantity of it, when it may be got dry, in the ſummer. Whatever is uſed for this purpoſe, ſhould be renewed as often as it is ſufficiently impregnated by the urine and dung of the ſheep.

The well preparing of mixed dung, is, as Mr. Worlidge rightly inſiſts, a piece of huſbandry by no means to be neglected; for the more and better the dung is, the greater will be the crop; and an increaſe of the crop will augment the quantity of dung. On the contrary, a decay in the dung makes a decay in the crop, &c. The riſe, or fall, of the value of many farms in this kingdom muſt therefore neceſſarily depend upon the good or bad management of this eſſential part of huſbandry. *See the article* DUNG-HILL.

STERILE, barren, unfruitful.

STEW, a ſmall kind of fiſh-pond, the peculiar intention of which is to maintain fiſh, and keep them for the daily uſes of a family.

STONE-BREAK, or Engliſh ſaxifrage, a perennial plant common in paſture grounds. The root has a ſharpiſh and aromatic taſte. The ſtalks are round, ſtreaked, and reddiſh towards the bottom. The leaves are ſmooth, of a dark green, and divided twice into long, narrow, ſharp ſegments. The foot-ſtalks are membranaceous at the baſe. The flowers grow in looſe umbels; and of a pale yellow colour. The ſeeds are oval, ſtreaked, and red at the top.

"Every farmer, ſays a correſpondent of the editors of the Muſeum Ruſticum, knows which ſort of graſs he would wiſh to have predominant in his meadows: it would ſurely be very eaſy for him to ſave ſome of the ſeeds of ſuch graſs, and propagate it a-part till he had ſaved ſufficient to ſow, ſuppoſe an acre of land with it, pure and unmixed: when arrived at this point, he might propagate it as extenſively as he thinks proper.

"I muſt not however forget the chief intended ſubject

of

of my letter, which is, to recommend to your readers the ſaxifrage as a plant proper to be intermixed with the graſs of their meadows.

" I have now in my holding above thirty acres of meadow land, which fortunately for me bear a graſs that needs no improvement; though this I in part attribute to my having drained my land properly ſome years ago, ſince which the bite is much improved.

" Amongſt this graſs in my meadows there grows a conſiderable quantity of ſaxifrage; which, in the opinion of all the dairy-men in my neighbourhood, is the reaſon my cheeſe is ſo particularly good.

" Now I ſhould imagine that when a farmer has plowed up a foul meadow, and intends ſowing it with good graſs ſeed, it would be no difficult matter to procure a ſprinkling of ſaxifrage-ſeed to mix with it: this would certainly be of ſervice; and we ſhould not deſpiſe this excellent plant becauſe it is common, and not far-fetched: there is great plenty of it in the Netherlands, in their fineſt cow-paſtures; and that I have often heard aſſigned as a reaſon for their having ſuch quantities of cheeſe of a ſuperior quality; though I muſt at the ſame time own, I have in London taſted ſome Dutch cheeſe, ſtuffed full of cloves, which was not the beſt in the world; but this might have been an accident, for they ſay their cheeſe is in general excellent.

" But, to return to my immediate ſubject, I would by all means recommend the propagation of the ſaxifrage plant in meadows, not only on account of its great uſe in improving the quality of cheeſe, and butter alſo, which it does, but becauſe it is a native of our iſland, and there is no danger of its ſucceeding to the farmer's wiſh; which cannot be ſaid of every plant recommended for cultivation.

" But it muſt be remembered, that I do not recommend it to be cultivated alone; I never tried it in that manner: that it will thrive very well when mixed with good meadow graſs, daily experience convinces me; and this method it is I urge." *Muſeum Ruſticum, vol.* I. *page* 472.

The burnet, cultivated to ſo much advantage by Mr. Rocque and others is a ſpecies of the ſaxifrage. *See the article* BURNET.

STONE, a hard ſolid body, neither molliable, fuſible by fire, nor ſoluble in water; formed by ſucceſſion of time in the bowels of the earth.

It has been argued, and is not yet determined, whether ſtones are hurtful, or beneficial, to arable lands. Examples are not wanting on both ſides of the queſtion; though, in general, it ſeems rather to be carried for them. However, nothing can excuſe leaving a ſtone in any ground ſo large as to interrupt the plough. If they are very large, they ſhould be blown to pieces with gun-powder, and then be carried off. Some ſpots, very fertile in ſeveral kinds of grain, ſeem to conſiſt of nothing but ſtones; and inſtances are given of fields being rendered barren by taking away the ſtones which covered them. Theophraſtus accounts for this in a hot country, where it happened to the Corinthians, by ſaying, that the ſtones ſhelter the earth from the ſcorching heat of the ſun, and thereby preſerve its moiſture. The ſame holds true even in our colder latitude, where the heat of the ſun is leſs apt to hurt us; and Mr. Evelyn is clearly of opinion that huſbandmen rather impoveriſh, than improve, thoſe grounds which are almoſt covered with ſtones, eſpecially where corn is ſown, if they pick them off too minutely; becauſe they thereby expoſe the land too much to the effects of heat and cold. Certain it is, that a moderate mixture of ſmall gravel preſerves the earth both warm and looſe, and prevents too ſudden exhalations. But it ſeems highly probable that there muſt be ſome farther reaſon, beyond what has yet been aſſigned, for the benefit ariſing from ſtones. The example already given of the ſtone uſed in Oxfordſhire; and a remarkable incident which happened to M. Du Hamel, give great room to think that the ſtones which are thus beneficial, are of the lime-ſtone or calcarious kind.

" The ſtone which is uſed for building at Denainvilliers, ſays M. Du Hamel, is very hard. It bears poliſhing like marble; and is here and there intermixed with ſhells, ſome of which are filled with a kind of oaker, and others contain a cryſtaline ſubſtance. This ſtone is very fit to make lime of. Some workmen, who were building about our houſe, cut pieces of this ſtone upon a graſs-plat. When they had done their work, the rubbiſh was cleared away, and nothing was left upon the graſs but the duſt and very ſmall fragments, which had fallen from the ſtones in cutting them. The next year, the graſs grew ſurpriſingly thick in all the places where theſe ſtones had been cut, was much taller and greener than any where elſe, and preſerved its vigour for ſeveral years. One would ſcarcely have thought that ſo hard a ſtone, reduced to powder would have produced an effect like that of marle. The goodneſs of lime, as a manure, is, perhaps, chiefly owing to the fineneſs of the powder, to which the lime-ſtones are reduced by calcination.

" This fact may help to clear up another, which cannot have eſcaped the notice of thoſe who attended to the differences of ſoils. They muſt have obſerved ſome grounds ſo thickly covered with ſtones, that ſcarce any thing elſe is ſeen after a heavy ſhower of rain. Yet ſome of theſe lands are very fertile, and produce fine wheat. I know not whether I am miſtaken; but I think I have obſerved that this fertility is found only in fields where thoſe ſtones are calcarious. It is very probable that the duſt which is formed by the mutual rubbing of theſe ſtones contribute to that fertility." *Culture des Terres, tom.* V. *page* 220.

The farmer may eaſily inform himſelf whether this be the caſe; and if it is, he has a certain rule to go by in the management of ſtones; viz. by trying with aqua fortis, or ſpirit of ſea-ſalt, as mentioned before, whether they are calcarious or not: for every ſtone on which the ſpirit does not effervеſce, is of no uſe, and therefore ſhould be removed, as an impediment to the neceſſary labour. However, the prudent huſbandman will make the experiment of clearing his land, firſt on a ſmall ſpot; that he may be ſure of the ſucceſs, before he embarks in a greater expence. *See the article* LIME.

STONE, alſo denotes a certain quantity or weight of ſome commodities.

A ſtone of beef at London is the quantity of eight pounds; in Hereſordſhire, twelve pounds; in the north ſixteen pounds.

A ſtone of wool, according to a ſtatute made in the eleventh year of the reign of Henry VII. is to weigh fourteen pounds, but in ſome places it is more, in others leſs; as in Glouceſterſhire fifteen pounds, in Hereſordſhire twelve pounds.

A ſtone, among horſemen, is the weight of fourteen pounds.

STONY-LANDS, ſuch as are full of flints, pebbles, or ſmall fragments of free ſtone.

These lands, in many places, yield good crops, and the general rule is, that in ſtiff and cold lands the ſtones ſhould be as carefully picked out as poſſible, but in light and dry grounds they ſhould be left. In Oxfordſhire they have great quantities of a lean earth, and a ſmall rubble ſtone, or a ſour ſort of land mixed with it; this is ſometimes very full of weeds, and ſometimes very clear of them. If they are weedy they fallow them late; but if they are ſcary, as they call it, that is, if they have a ſward upon them, they either fold them in winter, and add ſome hay-ſeed to the ſheep's dung, to bring up the graſs; or elſe they lay old thatch or ſtraw, and dung upon it: for they reckon that if thoſe lands have no ſward upon them before they are fallowed, they will by no means be brought to bear a good crop, but a great deal of May-weed, and other uſeleſs weeds. In September, November, and December, they fallow as the ſward directs them: if this be done in either of the two laſt months, they call it a winter fallowing; and never ſtir it again, till they plow it, and ſow it with barley; and thoſe lands are reckoned to do better than if finely tilled. They will bear wheat and meſlin in a kindly year, and large crops of barley, if they are well managed, and kept in good heart.

They always fallow theſe lands every other year, unleſs they ſow peas upon them; ſometimes they ſow them with lentils; and, when they are quite worn out, they lay them down for clover or rey-graſs.

STOOKING, SHOCKING, *or* STACKING, the ſetting the ſheaves into ſhocks, the better to guard it from the rain.

A correſpondent of the editors of the Muſeum Ruſticum, has given us the following method of ſtacking, or ſtooking corn to preſerve it from the wet, and in which ſituation it may remain in the field ſix weeks or two months, without any danger from the inclemency of the weather.

"They ſet one ſheaf upright with the ears uppermoſt; and round that they place a circle of many other ſheaves, with their ears uppermoſt, inclining on the firſt ſheaf; and when ſo placed they look like the figure of an extinguiſher.

"Then they lay an horizontal circle of ſheaves, with all the ears in the center, and cover thoſe ears with a looſe ſheaf or two.

"Thus placed they are protected from all wet, and may remain in the field ſix weeks, or two months, as ſafe as in a barn; and this method of ſtacking has been adopted in Suſſex, Surry, Kent, and many other ſouthern counties, to the great benefit of the farmers and the public." *Muſeum Ruſticum, vol.* II. *page* 35.

In a ſubſequent number of the ſame work, the Rev. Mr. Comber, of Eaſt-Newton, in Yorkſhire, has made ſome remarks upon the above method of ſtooking, and alſo deſcribed the method followed in Yorkſhire.

"It is to be wiſhed, ſays he, that this gentleman had been more particular in his account. He does not tell us whether this ſtack, as he calls it, is made immediately after the wheat is gathered, or after it has had field-room in ſome other manner, though this circumſtance is very material towards a right judgment of its uſefulneſs, and even of the expedition. He does not tell us, whether by a circle of many other ſheaves he means a circle of one row of ſheaves, or of more, though this circumſtance too is very material.

"I will now give a ſhort, but, I hope, ſufficient deſcription of the method of ſtooking uſed in Yorkſhire, &c.

"Ten ſheaves are diſpoſed in two rows, each row leaning againſt the other: then two ſheaves are laid on the top, ſo as to meet at the centre with their tails, and to ſlope downwards.

Now to compare the methods, I muſt obſerve, firſt, that in your correſpondent's the ſheaves appear to be ſet ſo cloſe as to exclude a free courſe of air, moſt eſſential to give, preſerve, or reſtore, dryneſs to corn; whereas in ours, the air has a free courſe, whether it bears againſt one or other end of the ſtook, or even againſt either ſide of it.

"Secondly, in your correſpodent's method, only ſome looſe ears are laid as a cover to the whole ſtook; and thoſe cannot reaſonably be ſuppoſed long to reſiſt the beating of the rain, but to tranſmit it to all, or many of the ears below them, which they are ſuppoſed to cover: and if we conſider what violent winds often viſit us in, and ſoon after, the harveſt, we ſhall readily allow, that theſe looſe ears may reaſonably be expected to be blown off, and become no cover; nay, to be blown about and away, and often totally loſt; whereas, in our method, the cloſeneſs and weight of two of the beſt ſheaves in the twelve may reaſonably be ſuppoſed to be a good cover, and to continue ſo, and hardly to be blown off by any wind, if carefully laid on; at leaſt, not to be blown away, but ſo as ſoon to be replaced.

"Thirdly, the flat poſition of your correſpondent's cover, muſt make it extremely liable to receive all the rain that deſcends, and tranſmit it to what lies beneath; whereas the ſloping poſition of our cap ſheaves, neither expoſes them to receive directly, nor to retain, nor tranſmit the rain to the corn below, but to throw it off, eſpecially as the tails of the ſheaves, in which the ſtraw is thickeſt and ſtrongeſt, receive the moſt of the rain, which can do them little or no harm, and eſpecially if the tails of theſe ſheaves be thruſt cloſely together. In ſhort, gentlemen, your correſpondent's method ſeems to threaten that dreadful malady, mow-burn, whilſt ours gives the corn all poſſible guard againſt it, viz. acceſs of ſun and wind.

"It is of great conſequence to the public, as well as individuals, to guard againſt every ſpecies of deſtruction to ſo valuable a crop as wheat is, in every ſtage, but more eſpecially in its laſt, in which almoſt all the expence is over: therefore, the above gentleman's aſſertion, that his method of ſtacking is adopted in Suſſex, Surry, Kent, and many other ſouthern counties, made me more ſollicitous to examine it; and ſince, on a fair compariſon with our Yorkſhire method, it appears to have every diſadvantage, I perſuade myſelf I am doing my duty to my country by ſhewing to many counties a much better method than that which they have adopted. *Muſeum Ruſticum, vol.* II. *page* 250.

STOOMING *of wine*, is the putting bags of herbs, or other ingredients into it. *See the article* WINE.

STOOP, a poſt fixed in the earth.

STOT, a young bullock; a ſteer.

STOVER, fodder for cattle.

STOUND, a wooden veſſel to put ſmall beer in.

STOWK, the handle of a pail; alſo a ſhock of twelve ſheaves.

STOWRE, a round of a ladder; a hedge-ſtake: alſo the ſtaves in the ſides of a waggon, in which the eve-rings are faſtened.

STRAIN, or SPRAIN, a violent extenſion of the ſinews or tendons of ſome muſcle, where by the tendinous fibres are overſtretched, and ſometimes ruptured, or broken.

To

To form therefore a true idea of theſe diſorders, let us firſt conſider every muſcle, and tendon, as compoſed of ſpringy elaſtic fibres, which have a proper power of their own, to contract and extend themſelves: or, to make their action more familiar, let us compare them to a piece of catgut, that we may the better judge with what propriety oily medicines are directed for their cure. Thus then, if by a violent extenſion of this catgut, you had ſo overſtretched it, as to deſtroy its ſpringineſs or elaſticity, and was inclined to recover its loſt tone; would you for that purpoſe think of ſoaking it in oil? And is not the method of treating ſtrains, or overſtretched muſcles and tendons, full as prepoſterous, when you bathe or ſoak them in oily medicines, at a time when they want reſtringents to brace them up? Yet cuſtom has ſo eſtabliſhed this practice, and fallacious experience ſeemingly ſo confirmed it, that it would be a difficult taſk to convince the illiterate, and prejudiced, of the abſurdity; who, by attributing effects to wrong cauſes, are led into this error, and the oils uſurp the reputation that is due only to reſt and quiet: they ſeem however to be aware of the ill conſequences, by their adding the hot oils, as ſpike, turpentine, and origanum; which, though they in ſome meaſure guard againſt the too ſuppleing quality of the other oils; yet the treatment is ſtill too relaxing to be of real ſervce.

And indeed in all violent ſtrains of either tendon or muſcles, whatever opinion we may entertain of bathing and anointing with favourite noſtrums, which often ſucceed in ſlight caſes, where perhaps bandage alone would have done; yet it is the latter, with proper reſting the relaxed fibres, till they have thoroughly recovered their tone, that are the chief things to be depended on; and frequently ſome months are neceſſary for effecting the cure.

All violent ſtrains of the ligaments, which connect the bones together, eſpecially thoſe of the thigh, require time, and turning out to graſs, to perfect a recovery. External applications can avail but little here, the parts affected laying too deep, and ſo ſurrounded with muſcles, that medicine cannot penetrate to them. The ſooner in theſe caſes, a horſe is turned out to graſs, the better, as the gentle motion in the field will prevent the ligaments and joint oil, from thickening, and of courſe the joint itſelf from growing ſtiff; nor do I believe that firing, ſo commonly practiſed in this caſe, is of half the conſequence as reſt, and turning out for a conſiderable time; which by the bye, is always adviſed at the ſame time the horſe is fired. I could not avoid ſaying thus much, in order to ſhew the great advantages of reſt in all ſtrains, and that no horſe ſhould be worked till he is thoroughly recovered.

When a horſe's ſhoulder is overſtrained, he does not put out that leg as the other, but to prevent pain, ſets the ſound foot hardly on the ground, to ſave the other; even though he be turned ſhort on the lame ſide, which motion tries him the moſt of any. When trotted in hand, inſtead of putting his leg forward in a right line, he forms a circle with the lame leg; and when he ſtands in the ſtable, that leg is advanced before the other.

In order to cure this lameneſs, firſt bleed him, and let the whole ſhoulder be well bathed three times a day with hot verjuice or vinegar, in which may be diſſolved a piece of ſoap; but if the lameneſs continues without ſwelling, or inflammation, after reſting two or three days, let the muſcles be well rubbed for a conſiderable time, to make them penetrate, with good opodeldoch, or either of the following mixtures:

Take camphorated ſpirits of wine two ounces; oil of turpentine one ounce; this proportion will prevent the hair coming off.

Or,

Take the beſt vinegar half a pint; ſpirit of vitriol, and camphorated ſpirit of wine, of each two ounces,

When the ſhoulder is very much ſwelled, it ſhould be fomented with woollen cloths (large enough to cover the whole) wrung out of hot verjuice and ſpirit of wine; or a fomentation prepared with a ſtrong decoction of wormwood, bay-leaves, and roſemary, to a quart of which may be added half a pint of ſpirit of wine.

A rowel in the point of the ſhoulder in this caſe often does great ſervice; eſpecially if the ſtrain has been very violent, and the ſwelling very large; but as to boring up the ſhoulder with a hot iron, and afterwards inflating it, is both a cruel and abſurd treatment; and the pegging up the ſound foot, or ſetting on a patten ſhoe, to bring the lame ſhoulder on a ſtretch, is a moſt prepoſterous practice, and directly calculated, to render a horſe incurably lame; for it can only be neceſſary in caſes the very oppoſite to this, where the muſcles have been long contracted, and we want to ſtretch them out.

Where poultices can be applied they are at firſt undoubtedly very effectual, after bathing with hot vinegar or verjuice, and are to be preferred greatly to cold charges, which by drying ſo ſoon on the part, keep it ſtiff and uneaſy; let them be prepared with oatmeal, rye-flour, or bran boiled up in vinegar, ſtrong beer, or red wine lees, with lard enough to prevent their growing ſtiff; and when by theſe means the inflammation and ſwelling is brought down, bathe the part twice a day with either of the above mixtures, opodeldoch, or camphorated ſpirits of wine; and rowl the part three or four inches, both above and below, with a ſtrong linen rowler, of about two fingers width; which will contribute not a little to the recovery, by bracing up the relaxed tendon; and perhaps is more to be depended on than the applications themſelves.

As opodeldoch is variouſly made, and thoſe uſually ſold in the ſhops, do not ſeem ſo well calculated for horſes, we ſhall inſert the following; as better adapted to this purpoſe, and recommend it to be kept ready prepared for the uſe of the ſtable; it being not only very proper for the above uſe, but for bruiſes, cold ſwellings, benumbed parts, and for diſperſing many other ſuch ſort of tumours: it may occaſionally alſo be given internally for the gripes from wind, or taking cold; for the ſtrangury alſo, and as a cordial; one ounce, or more, may be taken for a doſe, in a pint of ale.

Take Jamaica pepper four ounces, winters bark, carraway ſeeds, laurel, and juniper berries bruiſed, of each two ounces; roſemary, marjoram, and lavender flowers, of each one ounce; rectified ſpirit of wine, three pints; let them digeſt in a warm place ten days, then ſtrain off the tincture, and diſſove in it Venice ſoap a pound and a half; camphor three ounces; Barbadoes tar four ounces; oil of turpentine ſix ounces; oil of amber two ounces; mix and make a liniment.

In ſtrains of the coffin joint that have not been diſcovered in time, there will grow ſuch a ſtiffneſs in the joint

that the horſe will only touch the ground with his toe; and the joint cannot be played with the hand; the only method here is repeated bliſtering, and then firing ſuperficially.

Strains of the back ſinews are very common, and are eaſily diſcovered by the ſwelling, which extends ſometimes from the back ſide of the knee down to the heel, but for the moſt part the horſe ſets that leg before the other. The tendon ſhould be well bathed three or four times a day with hot vinegar; and if much ſwelled, apply the poultices above recommended, and when the ſwelling is down, bathe with the mixtures above, or with camphorated ſpirit of wine and oil of amber, in which is diſſolved as much camphor as the ſpirits will take up, and rowl up the tendon with a proper bandage, or laced ſtocking; which laſt properly fitted to the limb, might be wore to great advantage; not only in theſe kind of injuries, but in moſt others, where there is a diſpoſition to the greaſe, or other ſwellings of the limbs, from weak and relaxed fibres. Curriers ſhavings wetted with vinegar have been found uſeful for this purpoſe; as has alſo tar and ſpirit of wine: but where the tendon has ſuffered by repeated injuries of this kind, the caſe will demand bliſtering, firing, and proper reſt.

Strains of the knees and paſterns ariſe frequently from kicks, or blows; if they are much ſwelled, apply firſt the poultices; and when the ſwelling is abated, bathe with the above, or the following.

Take vinegar one pint; camphorated ſpirits of wine, four ounces; white vitriol, diſſolved in a little water, two drams.

Or,

Take the whites of three or four eggs, beat them into a froth with a ſpoon; to which add an ounce of roach allum finely powdered; ſpirit of turpentine, and wine, of each half an ounce; mix them well together.

The following is alſo much recommended by the French writers, and has been found very ſucceſsful in ſome old ſtrains, when other remedies have failed.

Take one pound of tar, and two of rectified ſpirit of wine, ſtir them together over a fire till they incorporate (but take care the flame does not catch the ſpirits) then add two ounces of bole finely powdered; and a ſufficient quantity of oatmeal to bring it to the conſiſtence of a poultice; to which add lard enough to prevent its growing dry; apply it ſpread on cloth twice a day.

As great weakneſs remains in the paſterns after violent ſtrains, the beſt method is to turn the horſe out to graſs till he is perfectly recovered; when this cannot be complied with, the general way is to bliſter and fire.

When a horſe is lame in the ſtifle, he generally treaps on his toe, and cannot ſet the heel to the ground. Treat him at firſt with the vinegar and cooling reſtringents; but if a large ſwelling with puffyneſs enſues, foment it well with the diſcutient fomentation till it diſperſes; and then bathe the part with any of the above medicines.

A lameneſs in the whirle bone and hip, is diſcovered by the horſe's dragging his leg after him, and dropping backward on his heel when he trots. If the muſcles of the hip are only injured, this kind of lameneſs is cured eaſily; but when the ligaments of the joint are affected, the cure is often very difficult, tedious, and uncertain. In either caſe, at firſt bathe the parts well with the cooling medicines, four or five times a day; in the muſcular ſtrain, this method alone may ſucceed, but in the ligamentous, it is reſt and time only can reſtore the injured parts to their proper tone.

Strains in the hock are to be treated by ſoaking the parts with coolers and repellers; but when the ligaments are hurt, and they are attended with great weakneſs and pain uſe the fomentation. If a hardneſs ſhould remain on the outſide, it may be removed by repeated bliſtering; if within, it may be out of the power of any external applications to remove; however the joint ſhould be fired gently with ſmall razes or lines pretty cloſe together, and then covered with a mercurial plaſter. To the diſcutient fomentation above mentioned may be added crude ſal armoniac, with a handfull of wood-aſhes boiled in it.

The bliſtering ointment for the above purpoſes may be found under the article SPAVIN; but the ſublimate ſhould be omitted.

The firing uſed for the ſtrengthening relaxed ſinews or tendons, ſhould act only on the ſkin, which by contracting and hardening it all round the ſinews, compreſſes them more firmly like a bandage. *See the article* FIRING *Bartlet's Farriery, pag.* 224.

STRANGLES, a diſtemper to which colts and young horſes are very ſubject; and begins with a ſwelling between the jaw-bones, which ſometimes extends to the muſcles of the tongue; and is attended with ſo great heat, pain and inflammation, that ſometimes till matter is formed the horſe ſwallows with the utmoſt difficulty.

The ſymptoms are extraordinary heat and feveriſhneſs, with a painful cough, and a great inclination to drink without being able; ſome horſes loſing their appetites intirely, others eating but little, by reaſon of the pain which chewing and ſwallowing occaſions: when the ſwelling begins on the inſide of the jaw-bones, it is much longer in coming to matter than when more to the middle; when it ariſes among the glands, and divides into ſeveral tumours, the cure is generally tedious, as it breaks in different places, and when it forms upwards on the wind pipe and gullet, there is ſometimes danger of ſuffocation, unleſs the ſwelling ſoon breaks. But the moſt dangerous kind is, when, beſides the above ſymptoms, the horſe runs at the noſe; this by ſome is called the baſtard ſtrangles.

As this diſorder ſeems to be critical, the moſt approved method is to aſſiſt nature in bringing the ſwellings to maturity, by keeping them conſtantly moiſt with ointment of marſhmallows, and covering the head and neck with a warm hood. But as all ſwellings in glandular parts ſuppurate ſlowly, the following poultice may be applied hot twice a day; it is alſo a very proper one to ripen, or bring any other ſwelling to matter.

Take leaves of marſhmallows ten handfuls; white lilly-root half a pound; linſeed and fenugreek ſeed bruiſed, of each four ounces: boil them in two quarts of water till the whole is pulpy, and add four ounces of ointment of marſhmallows, and a ſufficient quantity of hogs lard, to prevent its growing ſtiff and dry.

In

In five or six days, by theſe means, the matter is generally formed, and makes its way through the ſkin; and if the diſcharge is made freely and with eaſe, the opening need not be inlarged; but ſhould be dreſſed with the following ointment ſpread on tow, ſtill continuing the poultice over it to promote the digeſtion, and prevent any remaining hardneſs.

Take roſin and Burgundy pitch, of each a pound and a half; honey and common turpentine, each eight ounces; yellow wax four ounces: hogslard one pound; verdigreaſe finely powdered one ounce: melt the ingredients together, but do not put in the verdigreaſe, till removed from the fire; and it ſhould be ſtirred in by degrees, till the whole is grown ſtiff and cool.

If the fever and inflammation run high, and the ſwelling be ſo ſituated as to endanger ſuffocation, a moderate quantity of blood muſt be taken away, and the remainder diluted with plenty of water gruel, or warm water, maſhes, &c.

The running at the noſe, which often attends the ſtrangles, is dangerous; eſpecially if it continues after they have ripened and broke, as the horſe will be greatly weakened thereby. To prevent this waſte and decay, give him every day for ſome time an ounce of Jeſuits bark; or a ſtrong decoction of guaiacum ſhavings, which had been found extremely beneficial in reſtraining theſe glandular diſcharges when too liberal, and in drying up ulcers of all kinds in horſes. *See the article* GLANDERS.

If a hardneſs remains after the ſores are healed up, they may be anointed with the mercurial ointment; and when the horſe has recovered his ſtrength, purging will be neceſſary.

STRANGURY, a diſeaſe incident to cattle, conſiſting in a difficulty of making urine, attended with great pain. *See the article* KIDNEY.

STRAW, the ſtalk on which corn grows, and from which it is thraſhed. *See the articles* DUNG *and* RICK.

STRAWBERRY-TREFOIL. *See the article* TREFOIL.

STRICKLE, the whet-ſtone placed upon the extretremity of the ſhaft of a ſcythe.

STRIKE, a buſhel, or four pecks of corn.

STRINGHALT, a diſeaſe in horſes, conſiſting in a twitching and ſnatching up of the hinder leg much higher than the other.

STUBBLE, the ſtalks of corn left in the field by the reaper.

It has been a diſpute among farmers, whether wheat-ſtubble ſhould or ſhould not be ploughed in. We ſhall therefore give the following remarks of a ſenſible vale-farmer on this ſubject.

"We are far from being advocates, ſays he, for plowing in ſtubble; yet our land is not light, but the contrary, and bears as good crops of wheat as any in the kingdom.

"As our ſoil is not light, it agrees very well with horſe-beans, which we frequently ſow after wheat; but if ever we let the ſtubble remain uncut till bean-ſeaſon, and plow it in, the conſequences are ſurely fatal; it cauſes the earth to lie hollow; the bean plants to fall down; the ſun and air get at the roots, and prevent the plant thriving; and the crop is always very greatly leſſened: beſides, the ſtubble, which with us is very ſtrong, clogs the plow-

ſhare, and gathers up in clods, which are a ſure and a fatal ſhelter for many noxious inſects.

"Theſe facts, which every vale-farmer is well acquainted with, induce us always to mow our ſtubbles, which we apply to many and various uſes: if it is long, it ſerves very well for thatching: we litter our yards, ſtables, and cow-houſes with it for making dung; we uſe it for drying malt; and a great deal is burnt by the poor cottagers, for warming themſelves in winter, dreſſing their victuals, baking, brewing, *&c.*" *Muſeum Ruſticum*, *vol.* III. *p.* 225.

STUM, the unfermented juice of the grape, after it has been ſeveral times racked off, and ſeparated from its ſediment.

STUMP, the part of any ſolid body, particularly of trees, &c. remaining after the reſt are taken away.

A bare view of Fig. 6. Plate XXIV. is ſufficient to explain a very ſimple engine which Mr. Evelyn gives, for pulling up large roots.

The handle *A* turns the ſpindle of the pinion *B*, which has four or five teeth. Theſe teeth turn the larger wheel *C*, which moves the cylinder *D*, on which the rope *E* is rolled as the root is drawn up; one end of the rope being previouſly faſtened to the cylinder. The whole frame is let into a block of wood *F*, about four feet high and one in breadth; and the other end of the roller or cylinder is ſuſtained by a leſſer block of wood *G*. *H* is an iron plate which holds the wheel and pinion in the larger block. The cylinder, wheel, pinion, and handle of this machine ſhould be made of good tough iron. The cylinder may be about four inches in diameter, and fourteen or ſixteen inches in length. The reſt is obvious: though I apprehend an improvement might be made, by adding a catch, to ſecure either the handle or the cylinder, while the labourer (for one man will eaſily manage this engine) may be obliged to ſuſpend his work, in order to clear away any obſtacle that may have occurred. It would likewiſe certainly be right to place the wheels, and conſequently the handle, ſomewhat higher than is here directed, to ſave the very great fatigue of ſtooping down continually while this laſt is turned.

Where the roots are very large, and obſtinately tenacious, M. de Turbilly's advice, to blow them up with gunpowder, will be found very beneficial; eſpecially if the above inſtrument cannot be had.

Where a place has been over-grown with wood, the earth is ſo thoroughly ſtirred by digging and pulling up the ſtumps and roots of the trees, that one plowing in autumn is generally ſufficient. The froſts in winter kill the weeds and break the clods; and after a ſecond plowing, in the ſpring, theſe lands may be ſown with expectation of an abundant crop: for the trees not having exhauſted the earth towards the ſurface, but having on the contrary manured it with their leaves, a conſiderable produce may be expected for many years.

M. Du Hamel mentions a ſmall field, which had formerly been underwood, and being converted into arable ground, produced plentiful crops of wheat and oats for upwards of twenty years running, without being reſted. It is true the ſoil was peculiarly proper for wheat, and would have been exhauſted much ſooner if it had been a poorer earth.

STUMPY, full of ſtumps; hard, ſtiff.

STURK, a young bullock; a heifer.

STY, a cabbin, or ſmall building to keep hogs in.

SUCCULENT, juicy, moiſt.

SUCKER, a young twig, or ſhoot from the root.

SUFFOLK-GRASS, the ſame with meadow-graſs, or poa. *See* POA.

SUILLAGE, a drain of filth.

SULL, a plough. *See the article* PLOUGH.

SULL-PADDLE, a plough paddle.

SUMMER, the ſeaſon in which the ſun arrives at the northern ſolſtice, and the days are at the greateſt length.

SUMMER, alſo implies the large piece of timber, or principal beam of a floor.

To SUMMER-LAND, or *To* SUMMER-STIR, to fallow land in the ſummer.

SUN-SCORCHED, a term uſed in ſome parts of England to expreſs a diſtemperature of fruit-trees, owing to the ſun's affecting them too forcibly on a ſudden; the conſequence of which is the loſs and withering of the fruit. Such trees only are ſubject to this, as are planted in places ſheltered from the ſpring ſun, and open to that of the ſummer; and may be always cured by proper waterings.

SURBATING, a term uſed by farriers to ſignify the ſole of a horſe's foot being worn, bruiſed, or ſpoiled by beating the hoof againſt the ground in travelling without ſhoes, or going in hot ſandy lands, or with a ſhoe that hurts the ſole, or the like. It alſo ſometimes happens by over-riding a horſe while young, before his feet are ſufficiently hardened, or even by the hardneſs of the ground, and high lifting of his feet. The ſigns of this defect are his halting on both fore-legs, going ſtiffly, and creeping as if foundered.

There is nothing better for ſurbated feet than tar melted into the foot, or vinegar, boiled with ſoot to a proper conſiſtence and poured into the foot boiling hot, with hurds over it, and ſplints to keep it in.

SURFEIT, a diſeaſe incident to horſes and other cattle.

Surfeits ariſe from various cauſes; but are commonly the effects of ſome diſeaſes not attended to, or that have been ill cured.

A horſe is ſaid to be ſurfeited, when his coat ſtares, and looks ruſty and dirty, though proper means has not been wanting to keep him clean. The ſkin is full of ſcales and dander, that lays thick and mealy among the hair, and is conſtantly ſupplied with a freſh ſucceſſion of the ſame, for want of due tranſpiration. Some horſes have hurdles of various ſizes like peas or tares: ſome have dry fixed ſcabs all over their limbs and bodies; others a moiſture attended with heat and inflammation; the humours being ſo ſharp, and violently itching, that the horſes rub ſo inceſſantly, as to make themſelves raw. Some have no eruptions at all, but an unwholeſome look, and are dull, ſluggiſh, and lazy: ſome appear only lean and hide-bound: others have flying pains and lameneſs, reſembling a rheumatiſm: ſo that in the ſurfeits of horſes, we have almoſt all the different ſpecies of the ſcurvy, and other chronical diſtempers.

The following method is uſually attended with ſucceſs in the dry ſpecies. Firſt take away about three or four pounds of blood; and then give the following mild purge, which will work as an alterative, and ſhould be repeated once a week, or ten days for ſome time.

> Take Succotrine aloes ſix drams, or one ounce; gum guaiacum half an ounce; diaphoretic antimony, and powder of myrrh, of each two drams; make into a ball with ſyrup of buckthorn.

In the intermediate days, an ounce of the following powder, ſhould be given morning and evening in his feeds.

> Take native cinnabar, or cinnabar of antimony, finely powdered, half a pound; crude antimony, in fine powder, four ounces; gum guaiacum, alſo in powder, four ounces: make into ſixteen doſes for eight days.

This medicine muſt be repeated till the horſe coats well, and all the ſymptoms of ſurfeit diſappear. If the horſe is of ſmall value, two or three common purges ſhould be given, and half an ounce of antimony, with the ſame quantity of ſulphur, twice a day, or the alterative balls with camphor and nitre, as directed in the preceding chapter.

If the little ſcabs on the ſkin do not peel off, anoint them with the mercurial ointment; during the time of uſing which, it will be proper to keep the horſe dry, and to give him warm water. This ointment properly rubbed into the blood, with the aſſiſtance of purging phyſic, has frequently cured theſe kind of ſurfeits, without any other aſſiſtance.

The wet ſurfeit, which is no more than a moiſt running ſcurvy, appears on different parts of the body of a horſe, attended ſometimes with great heat and inflammation; the neck oftentimes ſwells ſo in one night's time, that great quantities of a hot briny humour iſſues forth, which, if not allayed, will be apt to collect on the poll or withers, and produce the poll-evil or fiſtula. This diſeaſe alſo frequently attacks the limbs, where it proves obſtinate, and hard to cure: and in ſome horſes ſhews itſelf ſpring and fall.

In this caſe bleed plentifully, avoid externally all repellers, and give cooling phyſic twice a week; as, four ounces of lenitive electuary, with the ſame quantity of cream of tartar; or the latter, with four ounces of Glauber ſalts, quickened, if thought proper, with two or three drams of powder of jallap, diſſolved in water-gruel, and given in a morning faſting.

After three or four of theſe purges, two ounces of nitre made into a ball with honey, may be given every morning for a fortnight; and, if attended with ſucceſs, repeated for a fortnight longer.

The powders above-mentioned may alſo be given with the horſe's corn; or a ſtrong decoction of guaiacum ſhavings, or logwood may be given alone to the quantity of two quarts a day. Theſe, and indeed all alterative medicines, muſt be continued for a long time, where the diſorder proves obſtinate.

The diet ſhould be cool and opening, as ſcalded bran or barley; and if the horſe is hide-bound, an ounce of fenugreek ſeeds ſhould be given in his feeds for a month or longer; and, as this diſorder often proceeds from worms, give the mercurial phyſic too, and afterwards the cinnabar powders, as above directed; but as in general it is not an original diſeaſe, but a ſymptom only of many, in the cure, regard muſt be had to the firſt cauſe: thus as it is an attendant on ſurfeits, fevers, worms, &c. the removal of this complaint muſt be variouſly effected.

In a mangy horſe the ſkin is generally tawny, thick, and full of wrinkles, eſpecially about the mane; the loins and tail, and the little hair that remains in thoſe parts ſtands almoſt always ſtraſt out or briſtly: the ears are commonly naked and without hair, the eye and eye-

brows

brows the ſame; and when it affects the limbs, it gives them the ſame aſpect; yet the ſkin is not raw, nor peels off, as in the hot inflamed ſurfeit.

Where this diſtemper is caught by infection, if taken in time it is very eaſily cured: and I would recommend a ſulphur ointment as moſt effectual for that purpoſe, rubbed in every day. To purify and cleanſe the blood, give antimony and ſulphur for ſome weeks after. There are a great variety of external remedies for this purpoſe, ſuch as train oil and gun-powder, tobacco ſteeped in chamber-lye, &c. Solleyſell recommends the following.

Take burnt allum and borax in fine power, of each two ounces; white vitriol and verdigreaſe powdered, of each four ounces; put them into a clean pot, with two pounds of honey, ſtirring till they are incorporated; when cold, add two ounces of ſtrong aqua fortis.

But when this diſorder is cantracted by low feeding, and poverty of blood, the diet muſt be mended, and the horſe properly indulged with hay and corn. The following ointments are effectually uſed for this diſorder, rubbed into the parts affected every day.

Take powdered brimſtone, train oil, and tar, of each equal quantities; to which may be added ginger, or white hellebore.

Or,

Take ſulphur vivum, half a pound, crude ſal armoniac one ounce, hogs lard, or oil, a ſufficient quantity to form into an ointment.

Or,

Take quickſilver, and oil of vitriol, of each one ounce; hogs lard, one pound, ſulphur vivum four ounces, oil of turpentine one ounce and a half.

Theſe are both very powerful remedies for this diſorder, and can ſcarce fail of ſucceſs.

To the two firſt, occaſionally, may be added a third part of mercurial ointment; but as ſulphur is in general allowed, to be the ſpecific in the itch; and being found both more ſafe, and efficacious than mercury; ſo we apprehend it will ſufficiently anſwer the purpoſe here; for as this diſorder ſeems beſt accounted for by Leuwenhoek, from certain ſmall inſects he diſcovered in the puſtules, by the microſcope; ſo it ſeems as if they were deſtroyed, by the ſteams of brimſtone, though only raiſed by the heat of the body; for in the human body, the itch may be cured by partial ſulphureous unctions, on the legs only; but where the mange proves obſtinate in horſes, let the parts be waſhed with ſublimate water before the application of the ointment, and ſubjoin the internal uſe of ſulphur, in order to diffuſe the ſteams more certainly through the ſkin; there being reaſon to believe, as in the itch, that the animalcula may ſometimes lie too deep, to be thoroughly deſtroyed by external applications only.

SURVEYING, the art or act of meaſuring lands; that is, of taking the dimenſions of any field, parcel, or tract of land, laying down the ſame in a map or draught, and finding the content or area thereof.

As this art is of the utmoſt importance to all owners and occupiers of land, we ſhall endeavour to explain it in the eaſieſt and moſt intelligent manner. And in order to this we ſhall begin with the principles of the art, and proceed gradually to ſhew how all the ordinary figures may be meaſured, protracted, and caſt up, with no other inſtruments than chains, compaſſes and ſcales. We ſhall afterwards endeavour to explain, in a very eaſy and conciſe manner, the uſe of the plain table, and other inſtruments uſed in ſurveying; ſo that any perſon, of a common capacity, and that underſtands the four firſt rules of arithmetic, may be able to ſurvey and parcel out land, plot it, and give up its content with eaſe and expedition.

Of geometrical definitions, diviſions, and remarks.

I. A point is that which hath no parts, either of longitude or latitude, but is indiviſible, ordinarily expreſſed with a ſmall prick, like a period at the end of a ſentence.

II. A line hath length, but no breadth nor nepth, whoſe limits or extremities are points. This is either right or crooked.

III. A right line lies ſtreight, and equal between its extream points, being the ſhorteſt extenſion between them; the crooked or circular not ſo.

IV. A ſuperficies hath length and breadth, but no depth; of this, lines are the limits.

V. A plain ſuperficies in that which lieth equally (or evenly) between its lines.

VI. An angle is the meeting of two lines in one point, ſo as not to make one ſtreight line; and if drawn beyond that point, they will interſect or croſs one another. This in vulgar Engliſh may be called a corner; of which there be two ſorts, one right, the other oblique.

VII. A right angle is that which is made by two right lines, croſſing or touching one another perpendicularly, (or ſquarely) like an ordinary croſs, or carpenter's ſquare.

VIII. An oblique angle is that which is either greater or leſs than a right angle; and this is of two ſorts, obtuſe and acute.

IX. An obtuſe angle is greater than a right angle, like the left and right corners of a Roman X.

X. An acute angle is leſs than a right angle, like the higheſt and loweſt corners of the ſame letter.

XI. A figure is that which is comprehended under one line or many; of this there are two kinds, a circle, and a right-lined figure.

XII. A circle is a perfect round figure, ſuch as is drawn with a pair of compaſſes, the one foot being turned round in a point, and the other wheeled about it. The point in the preciſe middle is called the center; the round line, the circumference or periphert; a line going thro' the center, and divides the circle into two equal parts, is called the diameter; half of that line is a ſemi-diameter, or radius; half the circle is ſtiled a ſemi-circle; the quarter, a quadrant; any portion of it, cut off by a right line not touching the center, is called a ſegment

XIII. Right-lined figures are ſuch as are limited by three right lines, or more, and are either triangles or triangulate, that is, ſuch as are compounded of, and reſolvable into triangles.

XIV. Triangles are figures comprehended under three right lines, and (as Ramus thinks that for a reaſon he gives,

lib.

lib. 6. pr. 6.) might be better called trilaterals; but the name triangle from the number of the angles hath obtained.

Alſo from the nature and quantity of their angles, theſe triangles are diſtinguiſhed into three ſorts, 1. Rect-angled, having one right angle. 2. Obtuſe-angled, having one obtuſe angle. And 3. Acute-angled, having all acute angles; for no triangle can have more right or obtuſe angles than one, becauſe by a well known old rule, no triangle upon a plain ſuperficies can conſiſt of three greater angles than ſuch, as being jointly taken, are equal to two right.

Theſe three ſorts of triangles may, according to the length and proportion of their ſides, be ſub-diſtinguiſhed into ſeven; for each of them may have either two equal ſides or none; and the acute-angled may have all three ſides or lines equal: but be triangles of what name or kind ſoever, they are all capable of being exactly meaſured by one plain rule, as hereafter ſhall fully appear.

XV. Triangular figures are ſuch as have more angles, and conſequently more ſides or lines, than three; and theſe are either quadrangular or multangular.

XVI. Quadrangular figures are ſuch as have four angles, and as many ſides, and theſe are either parallellograms or trapeſias.

XVII. Parallellograms are figures that are bounded with parallel lines, that is, ſuch lines as are every where of the ſame diſtance one from another, ſo as if they were infinitely extended, they would never meet, like the upright lines of the Roman H. Theſe parallellograms are either rect-angular or obliquangular.

XVIII. Rect-angular parallellograms are ſuch as have four right angles, viz. the ſquare or quadrat, and the long ſquare, otherwiſe called the oblong.

XIX. The ſquare is that figure that hath four right angles, and four equal ſides, like any of the ſix faces of a die.

XX. The long ſquare hath alſo four right angle, and the oppoſite ſides are equal, but the adjoining ſides meeting at each angle, differ in length. Of this figure is a well printed page in a book, and the ſuperficies of a well cut ſheet of paper, or an ordinary pane of glaſs.

XXI. Obliquangled parallellograms are ſuch as have oblique angels, viz. two acute, and two obtuſe, of theſe there are two kinds, the rhombus, and the rhomboides.

XXII. The rhombus is a figure that hath equal ſides, but no right angles, like the form of a diamond on the cards, or the moſt ordinary cut of glaſs in windows, whoſe oppoſite angles are equal,

XXIII. The rhomboides is a defective rhombus; for if from any ſide of a rhombus we cut off a part with a parallel line, the remainder will be a rhomboides, which hath neither equal ſides nor angles, but yet the oppoſite ſides and angles are equal.

XXIV. The trapezium is a figure that is neither parallellogram, nor conſequently, hath equal ſides or angles, but is irregularly quadrangular, as if drawn at adventure. Of this ſhape moſt fields prove, that ſeem to the eye to be ſquares or oblongs.

XXV. Multangular figures are ſuch as contain more ſides and angles than four, and they are either regular or irregular.

XXVI. Regular multangulars take their names from their number of angles, ſo a pentagon, hexagon, heptagon, octagon, eucagon, decagon, ſignify multangular figures of five, ſix, ſeven, eight, nine, ten angles, and conſequently ſides.

XXVII. An irregular polygon, or multangular figure, is that which hath more angles, and ſides than four, the ſides, and angles, being unequal to one another.

Of geometrical problems.

I. *To draw a line parallel to another, at any diſtance aſſigned.*

Plate XXV. Fig. 1. Open your compaſſes to the diſtance given, and chuſing two points conveniently diſtant in the line given, as here at A and B, deſcribe the arches C and D, to whoſe convexity, if you apply a rule, the parallel line is eaſily drawn.

II. *To raiſe a perpendicular upon a line given, or to croſs that line at right angles in a point aſſigned.*

Fig. 2. Suppoſe the point C in the line A B were aſſigned for the perpendicular, open the compaſſes to a convenient diſtance, and mark out the two points E and F in the line A B, then opening them ſomewhat wider, you may, by ſetting one foot in E and F ſeverally, deſcribe the two arches cutting one another at the point D, from which, if you draw a line to the point C, the work is done for the raiſing of a perpendicular; but if you be to croſs the lines at right angles, you may continue the line from D thro' C at pleaſure.

But if the ſaid line A B had been given to be divided in the preciſe middle, by another line croſſing it at right angles, the way is to ſet one point of the compaſſes in A and B ſeverally, and having deſcribed two arches above the line interſecting one another at D, do the like below the line A B from the ſame points, and with the ſame extent of your compaſſes, then through the ſeveral interſections, a rule being laid upon them, a line may be drawn, cutting the given line exactly in the middle at right angles.

Note, That when one point of your compaſſes ſtand in A, you may make both the arches belonging to that center above and below the line; and then removing the compaſſes to B, you may croſs them both.

III. *To raiſe a perpendicular at the end of a line.*

Fig. 3. Let O R to be the line given, then to raiſe a perpendicular at R, make five little equal diviſions, and taking four of them with your compaſſes, ſet one foot of your compaſſes in R, and with the other deſcribe the arch P P; then take the diſtance from R to 5, and placing one foot in 3, with the other deſcribe the arch B B, interſecting the former in the point S; then ſhall the line S R (being drawn by a ſtrait rule) be a perpendicular to the line O R.

IV. *To let fall a perpendicular upon a given line from any point aſſigned.*

Open your compaſſes ſo as one foot being ſet in the aſſigned point, the other may go clear over the line given, and thereby deſcribe an arch cutting the line at two points; then ſhall the half diſtance between thoſe two points be the point to which the perpendicular may be drawn from the point aſſigned. But if you think it too much pains to find the point of half diſtance by trial, you may help yourſelf by the ſecond problem: for if you deſcribe two arches interſecting one another on the farther ſide of the line from the aſſigned point, placing (to that purpoſe) the foot of your

your compaſſes firſt in one of the interſections of the given line, and then in the other; you may by laying a rule upon the aſſigned point, and the interſection of the two arches, draw a perpendicular from the ſaid aſſigned point, cutting the given lines at right angles.

N. B. All theſe problems with regard to perpendiculars, aim at no greater matter, than what may be performed in a mechanical way with exactneſs enough by the help of a ſmall ſquare exactly made, for if you apply one leg of ſuch a ſquare to any line, ſo as the angle of the ſquare may touch the end of the ſaid line, or any other point where the perpendicular is to be raiſed, you may by the other leg draw the perpendicular. In the like manner to let fall a perpendicular from a point aſſigned, you need only to apply one leg of the ſquare to the line, ſo as the other may touch, at the ſame time, the aſſigned point, whence you may draw the perpendicular by that leg that toucheth the point.

If the handle of your ſquare be a little blunt, either thro' ill making or long uſing, you muſt allow for it when you apply it to a point in a line. And when you are drawing a perpendicular, you muſt ſtop before you reach the given line, and then by applying the leg of your ſquare to that part of the perpendicular already drawn, ſo as part of that leg may paſs clearly over the given line, you may draw the reſt of your perpendicular as exactly as if the angle had been true. This ſame method is to be taken when a line is to be croſſed by another drawn quite through it at right angles.

V. *An angle being given, to make another equal to it.*

Fig. 4. The angle X A D being given, and a line drawn at pleaſure, as is the loweſt from the point E, open your compaſſes to any convenient diſtance, and ſetting one foot in A, deſcribe the arch B C. Then with the ſame extent ſetting one foot in E, with the other deſcribe the arch C H, long enough to equal or exceed the other. Then taking the diſtance B C between the points of your compaſſes, ſet one in C, and with the other mark the point H in the arch C H, through which point H a line being drawn from the point E, will make an angle with the line E C, equal to the angle given.

Note, when we ſpeak of the quantity of angles, their equality or inequality, we never regard the length of the lines; for if you extend or contract them at pleaſure, the angle is ſtill the ſame. But that is the greateſt angle whoſe lines are fartheſt diſtant from one another at the ſame diſtance from the angular point, or the place where its lines meet.

VI. *Any three lines being given, (equal or unequal) ſo as no one of them be longer than the other two joined together, to make a triangle of them.*

Fig. 5. The lines A B C being given, ſet the line A from D to E; then with your compaſſes take the length of the line B, and ſetting one foot in D, deſcribe the arch P O. This being done, take with your compaſſes the length of the line C, and ſetting one foot in E, with the other croſs the former arch at F, from which interſection drawing lines by a rule to D E, the triangle is finiſhed.

Note, that if all the ſides, or two of them, be equal, the method is the ſame; but the labour leſs, becauſe we need not take the ſame length twice over with the compaſſes.

VII. *To find the perpendicular of the triangle, in order to the meaſuring of it.*

Fig. 6. Let the line A B be accounted the baſe, and from the angle C, let fall a perpendicular, as was taught Probl. 4. upon that line at D, which is ready for taking off with compaſſes, and meaſuring on a ſcale, of which hereafter in meaſuring the content of figures.

But if we have no occaſion to draw the perpendicular, but only to know the length of it, (as it moſt frequently falls out in meaſuring) no more is needful, but to ſet one foot of the compaſſes in the angular point C, and extend the other to the baſe A B, ſo as it may touch it, but not go beyond it; then have we the perpendicular between the points of the compaſſes.

VIII. *One ſide being given, to make a ſquare.*

Fig. 7. The line C D being given, raiſe a perpendicular at C of the length, at the leaſt, of the given line; then taking the line C D between the feet of you compaſſes, ſet it upon the perpendicular from the angular point C to A: with the ſame diſtance ſetting one foot in D, deſcribe the arch O P. Laſtly with the ſame diſtance, or extent, ſet one foot in A, and with the other deſcribe the arch croſſing the arch O P in N, from which interſection a line drawn by a rule to A, and another to D, finiſh the geometrical ſquare or quadrant A C D N.

IX. *To make a long ſquare, the length and breadth being given.*

This is ſo nearly like the former, that a particular figure is not neceſſary to explain it. Suppoſe each ſide of the ſquare in the laſt problem to conſiſt of 8 ſmall equal parts, and you were to make a long ſquare, whoſe length muſt be equal to a ſide thereof, viz. 8. and the breadth half ſo much: when you had drawn the line C D, for the length, and raiſed the perpendicular at C, you muſt take the ſhorter line given for the breadth, and ſet upon the perpendicular from C, upwards to a point, which for diſtinction we ſhall call the point E, imagining it ſo marked: with the ſame extent of the compaſſes deſcribe the arch, placing one foot in D. Laſtly, extending your compaſſes to the length of the line C D, ſet one foot in E, and with the other croſs the arch aforeſaid. Then a right line drawn from that interſection to E, and another from the ſame to D, complete the long ſquare.

X. *To make a rhombus, the ſides being given.*

Fig. 8. If the angles be not limited, draw any oblique angle at pleaſure, either acute or obtuſe, as here the angle B A C, which is acute. Then let the line O P be the length of a ſide, which being taken with your compaſſes, ſet it from the angular point A, in both lines to D and E, in which two points, place a foot of your compaſſes ſucceſſively without altering them, viz. in D, to deſcribe the arch F G, and in E, to deſcribe the arch H I, croſſing one another in the point K, from which, right lines drawn to D and E, finiſh the rhombus D A E K.

Note, If any angle be given together with the ſide, to limit the ſhape and content, begin with that, and proceed as before; for you muſt know, that to make a rhombus (or rhomboides) like to another for figure, or equal to it

in content, it is not ſufficient to have the ſame ſides; for the more oblique the angles are, the farther will the rhombus differ from a ſquare, and the leſs will be the content. But you muſt have an angle given, or elſe a diagonal line, which is a right line paſſing through the rhombus from one oppoſite angle to another, and dividing the figure into two equal triangles. If the former, viz. an angle, be given, we have ſhewed what uſe is to be made of it. If the latter, *i. e.* a diagonal, together with the length of the ſides, you may, by taking the length of your ſides with your compaſſes, and ſetting a foot in the ends of the diagonal line, make a triangle on the one ſide of the diagonal, by Probl. 6. and then another on the other ſide by the ſame problem, the diagonal being a common baſe to them both; and this will give the figure exactly.

XI. *To make a rhomboides, the ſides being given.*

Fig. 9. If neither angle nor diagonal be given, make any angle at adventure, as here A B C. Then ſuppoſing the lines given to be O P and Q R, ſet the length of the longer upon the line B C, from B to D, and the ſhorter on the line B A to E. Then with the compaſſes extended from B to E, ſet one foot in D, and deſcribe the arch F G. Likewiſe, with the compaſſes extended to the length of the line O P, ſetting one foot in E, with the other deſcribe the arch H I, interſecting the former arch at K; from which interſection lines drawn to D and E, finiſh the rhomboides.

XII. *To make a trapezium, the diagonal and lines in order being given.*

Fig. 10. Let the line HL be the diagonal of a trapezium whoſe ſides are the lines A B C D; the ſide A being counted the firſt, as that which takes it, being from the point H, and the reſt in the order as they are marked alphabetically.

Then with your compaſſes ſet to the length of the line A, place one foot in H, and with the other deſcribe the arch EF. Next taking the length of the line B, with the one foot of your compaſſes placed in L, with the other make the arch G I, interſecting the former at K; from which point of interſection, lines drawn to H and L, make the triangle H K L.

Then with the extent of the line C, ſet one of the feet of your compaſſes at L, and deſcribe the arch O P. Laſtly ſetting them to the length of the line D, and placing one foot of your compaſſes in H, with the other make the arch S R, interſecting the former at Q; ſo ſhall lines drawn from Q, to L and H, make up the triangle L Q H, and finiſh the trapezium H K L Q.

We could have been much briefer in this problem, by referring to the 6th; but this being of very great and frequent uſe, we deſired to be very plain.

XIII. *To make a regular polygon, otherwiſe called a regular multangular, or multilateral figure, conſiſting of many equal ſides and angles, viz. above four apiece.*

Being ſatisfied what ſhall be the diſtance between the center and every angle, with that diſtance deſcribe a circle, which being equally divided into as many parts as the figure muſt have angles (or ſides, for they are equal in number) and lines drawn from the points of diviſion within the circle from point to point, (ordinarily called chords) the polygon is finiſhed, as in this diagram.

Fig. 11. Suppoſe an heptagon, or multangular figure of ſeven ſides, and as many angles, be to be deſcribed, every angle being deſigned to be diſtant from the center A, ſeven eights, or three quarters and a half of an inch; with that diſtance deſcribe the circle B C D E F G H, which being divided into ſeven equal parts, and lines drawn from point to point, the heptagon B C D E F G H will be therein included.

We ſhall rather leave our reader to find out the points of diviſion by many trials, than to puzzle him with the geometrical way for finding out chords to that purpoſe.

XIV. *Having the ſides of the triangles whereof it conſiſteth, orderly given, to make an irregular multangular, or multilateral figure.*

This will be more fully handled hereafter, when I come to ſhew the method of drawing plats of ground. In the interim I will give you a ſpecimen of an irregular pentagon.

Fig. 12. Having the lines of three triangles given, lay down the greateſt of the firſt, viz. 20, from A to B for a baſe, and by Probl. 6, make a triangle of it, and the other lines 16 and 10, viz. the triangle A B O.

Secondly, You find by the number 20 over the firſt line of the ſecond triangle, that it is the common baſe to them both; and therefore, by the ſame Probl. 6, make the triangle A B P of the lines, 20, 14, 18.

Laſtly, finding the baſe of the third triangle to be the ſame with 18, one of the ſides of the ſecond make the triangle P B Q of the lines 18, 11, 12: ſo is the quinquangular figure finiſhed.

How every line is to be found in its due order in this, or any other ſort of multangular figures, ſo as to give a true and exact account, not only of the ſuperficial content, but alſo of the figure and ſituation, is to be taught hereafter in the doctrine and practice of Protraction.

How to find the ſuperficial content of any right-lined figure, the lines being given.

As a foundation to what we ſhall ſay upon this ſubject, there are ſome few geometrical principles or theorems out of Euclid and Ramus, which we deſire may be remembered; and becauſe underſtanding is a great help to memory, we ſhall make uſe of a kind of ocular demonſtration; which though not ſo ſtrict and artificial as that which is to be found in the commentators upon Euclid in the quoted places, will be more ſerviceable becauſe more eaſily underſtood.

Theor. 1. *Every parallellogram being of the ſame length with the baſe of a triangle, and of the ſame height with the perpendicular of that triangle, is double to it.* Euclid 41. 1.

Fig. 13. Here are two equal oblongs, or long ſquares, A B C D and B E F C, and within them two triangles inſcribed, whoſe baſes are of the ſame length, and their perpendiculars, O P and Q R, of the ſame height with the oblongs. Now each of theſe triangles being parted into two right-angled triangles by their perpendiculars, then it is plain to the eye, and from the nature of diagonals, which ever divide a parallellogram into equal parts, that the two

new

new triangles OPD and OPC, which make up the firſt of the given triangles, are equal to the triangles D A O and OBC, which make up the remainder of the parallellogram A B C D. Therefore that parallellogram is double to that triangle, which was to be demonſtrated.

In like manner it is evident, that the parallellogram BEFC is double to the triangle C O F, becauſe C R Q is equal to B Q C, and Q R F is equal to Q E F.

Theor. 2. *All triangles having the ſame baſe, and lying between the ſame parallels, are equal.* Euclid 37. 1.

So in our laſt diagram, the two given triangles having baſes of the ſame length, and lying between the ſame parallels, are evidently equal, becauſe they are demonſtrated to contain each of them the exact half of the parallellograms, wherein they are inſcribed; and the parallellograms being equal, their halves muſt be equal alſo.

Theor. 3. *The ſides of the triangulate (that is, one that hath four or more ſides) are ever two more than the triangles of which it is made.* Ram. lib. 10. prop. 2.

Fig. 10, 12. This is plain by inſpection, if you view again the figures of the trapezium and irregular pentagon, in the 12th and 14th problems.

Theſe theorems being allowed to be true, the doctrine concerning the ſuperficial content of right-lined figures, might be reduced to a narrow compaſs; for he that knoweth how to huſband theſe three theorems, may eaſily take up theſe corollaries, *or dine inverſo.*

1. Any quadrangular figure, regular or irregular, may by a diagonal be parted into two triangles; any five-ſided figure by two diagonals into three triangles; and ſix-ſided figures into four by three diagonals, &c. by Theor. 3.

2. It is no matter of what ſhape the triangle is, as to the rule for meaſuring, for whether it be right-angled, acute-angled, or obtuſe-angled, and whether it have three, two, or no lines equal, it is only the length of the baſe, and height of the perpendicular, and is conſiderable by Theor. 2.

3. The true meaſure or content of any triangle, whether alone, or as part of any triangulate figure of 4, 5, 6, or more ſides, (and conſequently of the whole figure, by ſumming up the content of all the ſeveral triangles) is found by multiplying the whole baſe of the triangle by half the perpendicular, or the whole perpendicular by half the baſe; which being a rule of ſuch infinite uſe in ſurveying, we deſire it may be remembered; and that it may be underſtood, we ſhall give a plain example.

44 20
10 22
—— —
440 40
40
——
440

Fig. 6. Suppoſe A B the baſe of the triangle belonging to the 7th problem, to be 44, and the perpendicular C D to be 20: whether you multiply 44, the whole baſe by 10, the half of the perpendicular, or 20, the whole perpendicular by 22, the half baſe, the product gives the content 440, as is here apparent.

Having thus given a general method how all right-lined figures may be reduced to triangles, and ſo their contents found, we might paſs to the next head concerning inſtruments, and their uſe; but becauſe there are nearer ways in meaſuring particular kinds of triangulate figures proper to thoſe kinds, we ſhall briefly mention them.

I. *To find the contents of a ſquare, or long ſquare.*

Multiply the length by the breadth, the product gives the area or content.

Example of a ſquare.
17 inches length.
17 inches breadth.
——
119
17
——
289 ſquare inches.
——

Example of an oblong.
25 feet long.
13 feet broad.
——
75
25
——
325 ſquare feet.
——

II. *To find the area or content in meaſure of a rhombus.*

Let fall a perpendicular from one of the obtuſe angles upon the oppoſite ſide; that ſide multiplied by the perpendicular, gives the area.

20 yards the ſide.
14 yards the parpendicular.
——
80
20
——
280 ſquare yards.

III. *To find the area of a rhomboides.*

Divide it into two triangles by a diagonal drawn between either pair of the oppoſite angles, then from either of the other angles let fall a perpendicular upon that diagonal; then ſhall that diogonal, being multiplied by that perpendicular, give the area.

Example.

19 rods the diagonal.
5 rods the perpendicular.
——
95 ſquare rods the content.
——

IV. *To find the content of a trapezium.*

Fig. 10. Divide it by a diagonal into two parts from angle to angle, as the trapezium, Probl. 12. is divided by the diagonal H L, then from the other two angles, which in that figure are marked with K and Q, let fall perpendiculars upon the diagonal, half the ſum of thoſe perpendiculars being multiplied by the diagonal, or common baſe, gives the ſuperficial content.

Example.

Suppoſe in the trapezium before-mentioned the diagonal is 33, the perpendicular from K 13, and that from Q 15, the area or ſuperficial content is thus computed.

13 chains the firſt perpendicular.
15 the ſecond perpendicular.

28 the ſum of both perpendiculars.

14 their half ſum.
33 the diagonal.

42
42

462 ſquare chains the area.

V. *To find the content of a regular polygonial, or multangular figure, otherwiſe called multilateral.*

Draw a line from the center to the middle of any ſide; half of the perimeter, or of all the ſides, being multiplied by that line before-mentioned, gives the content.

VI. *To find the content of an irregular polygon, or many-ſided figure.*

Divide it into trapezias and triangles by diagonals, then find their content ſeverally, and ſum up all together.

Fig. 12. Suppoſe the polygon belonging to the laſt problem were given without the diagonals AB and BP; then by drawing thoſe diagonals, the figure is divided into three triangles, whereof two being upon the ſame baſe AB, make up a trapezium, whoſe content may be found juſt in the ſame manner as was taught even now in the fourth rule, having found the perpendiculars from O and P falling upon the line AB. Then there remains the triangle BQP, whoſe content may be found by the general rule concerning triangles, having found the perpendicular falling from Q on the line BP; and then having added the content of that triangle to the content of the trapezium, you have the area of the whole polygonial figure.

Concerning chains, compaſſes, and ſcales.

I. Amongſt the many ſorts of chains uſed for meaſuring land, three are moſt famous, bearing the names of their inventors, Mr. Rathborne, Mr. Gunter, and Mr. Wing, all of them ingeniouſly divided, and uſeful in their kind; but brevity will give us leave only to deſcribe one, and that ſhall be Mr. Gunter's, being moſt in uſe, and eaſy to be procured.

This chain contains in length, four ſtatute-poles or perches, each perch containing 16 feet and a half, or 5 yards and a half; ſo that the whole chain is 66 feet, or 22 yards long.

This whole chain is divided into 100 equal parts or links, whereof 25 are a juſt pole or perch; and for ready counting, there is uſually a remarkable diſtinction by ſome plate or large ring at the end of every 25 links, but eſpecially at the preciſe middle of the chain, which ſhould differ from the reſt in greatneſs and conſpicuouſneſs. Alſo at the end of every tenth link, it is uſual to hang a ſmall curtain-ring; and if there be at every five links end a piece of wire made like the bow of a link, with a little ſhank an inch or leſs long, or ſome ſuch diſtinction, it is ſtill better.

When you are to meaſure any line by this chain, you need to regard no other denomination but only chains and links, ſet down with a prick of your pen between them. *e. g.* If you found the ſide of a cloſe to be 6 chains and 35 links long, it is thus to be put down, 6.35.

But if the links be under 10, a cypher muſt be prefixed; ſo 7 chains 9 links muſt be thus ſet, 7.09.

In the uſing of this, or indeed of any, chain, care muſt be taken both to go ſtrait, and to keep a true account; for which purpoſe, it is good that he which goeth before, carry in his hand a bundle of rods, to ſtick down one at the end of the chain which leads, having firſt ſtretched it well, and that he which follows do not only gather up the rods to keep the account, but alſo at every remove, mark whether he ſee the leader directly between his eye and the angle, or other mark he aims to meaſure to; and if need be, call to the leader to move towards the right or left hand, till he ſee him in a direct line to it.

II. Compaſſes are ſo well known, that we need not deſcribe them; only they ſhould be of braſs, with ſteel points, ſmall and neatly wrought, nine or ten inches long from the joint to the points, turning ſo truly upon the rivet, that they may be eaſily opened, and yet ſtand ſo firmly, that an arch or circle may be, without their ſhrinking, deſcribed upon a large radius.

III. Scales are certain lines divided into equal parts, upon plates or broad rules of braſs or box, and they are of two ſorts, 1. Plain. 2. Diagonal.

1. Plain ſcales are made up of two ſmall lines parallel to one another at a little diſtance, and theſe are divided into great equal parts, which ſignify tens, and are noted 10, 20, 30, 40, 50, &c. according to the length of the lines.

They may be of any convenient length, but theſe great diviſions are ſeldom more than inches, or leſs than third parts apiece.

Again, one of the great diviſions is ſubdivided into ten equal parts by ſhort lines, whereof that in the middle ſtanding for 5, is longer than the reſt.

Fig. 13. According to the numbers of theſe little parts contained in an inch, the ſcale is named, A ſcale of 10, 11, 12, 16, 20, 24, 30, &c. in an inch. That ſhort one which we give you the figure of A, is of 10 in an inch, ſo noted at the top, according as is uſual upon the rules, and indices of plain tables. The line marked OQ, ſeparates units and tens; units being taken upward from that line, and tens downward; mixt numbers both ways.

As for example.

7 Is the extent of the compaſſes upon the ſcale A, from the line OQ to K; 30 is their extent from the line ſo marked to OQ; and 27 is their extent from the line 20, to the ſhort line K aforeſaid.

Here note, that you muſt not expect to find the letters OQ or K upon the ſcales which you buy, being only marks uſed at pleaſure, to make our meaning plain; and likewiſe that this ſcale of 10 in an inch, and others that are ſmaller are uſually made, for more convenient uſe, ſo long as to contain nine or ten of the great diviſions, ſignifying tens; though the figure at A being deſigned for no other uſe than to help our conceptions, extends but a little beyond 30, that length being ſufficient for my purpoſe in this place.

Fig. 14. Theſe plain ſcales, eſpecially the ſmaller ſorts of them, ſuch as 24 or 30 in an inch, are very proper for drawing figures upon paper, where the numbers repreſented

ſented by the lines are not above 100, for then every diviſion may be counted as it is upon the ſcale, or above upon a long ſcale.

Alſo in the ſurveying of foreſts, chaſes, and great commons, where the lines are vaſtly long, and the miſtake of a few lines is not conſiderable, they may be conveniently uſed, accounting the tens and units to ſignify ſo many whole chains, and ſo eſtimating the parts of a chain with the compaſſes upon the ſmall diviſions, which a ſagacious man may do very near upon one of the larger ſcales. But it would be much better for ordinary meaſuring, if the grand diviſions of the ſcale were two inches apiece, for then the ſmaller diviſions being of five in an inch, would be ſo large as to be ſub-divided into five apiece, which repreſents 20 links; and then the half one of thoſe ſmaller diviſions ſignifying 10 links, and the quarter 5, a very ordinary judgment may come very near to the truth by eſtimation.

2. But the diagonal ſcale is ſo well known to every mathematical-inſtrument-maker, ſo eaſy to be procured, and every way ſo fitted to Gunter's chain, that we cannot but highly commend it.

It is made, as appears by the figure B, upon eleven parallel lines equidiſtant, ſo as to include ten equal ſpaces, which are all cut at right angles by tranſverſe lines dividing them all into four equal parts.

One of theſe tranſverſe lines, *viz.* PR, where it toucheth the firſt and laſt lines, ſeparates between the hundreds, or whole chains, and the tens, repreſenting 10 links apiece, the chains being numbered downwards on the left hand from P only to 3, but on the inſtrument itſelf they may go on to 9 or 10, but the tens upward from P to 10.

From the points of diviſion into tens upon the firſt line, beginning at P, to the like points beginning at R in the laſt line are nine diagonal lines drawn, the firſt beginning at P, and ending at the firſt diviſion above R. The ſecond beginning at the firſt diviſion above P, and ending at the ſecond above R. In a word, they are all drawn from one diviſion leſs from P, to one more from R; by which it comes to paſs that every diagonal, by that time it hath paſſed from the firſt line to the eleventh, is a whole tenth part of an inch, which anſwers to ten links of the chain, farther diſtant from the line PR than at the points upon the firſt line whence it was drawn.

Every one of thoſe diagonals is divided into ten equal parts by the long parallel lines running through the whole ſcale, and numbered on the top from 1 to 9. Whereby it is evident that the interſection of any of the nine parallel lines that are numbered at the head with any diagonal, muſt be farther diſtant from the line PR, than the interſection of the line next before it with the ſame diagonal by $\frac{1}{10}$ of $\frac{1}{10}$, that is, by $\frac{1}{100}$, which anſwereth to a ſingle link of your chain.

From what hath been ſaid, and inſpection of the figure B, theſe things plainly follow; which, as ſo many clear inſtances, will help you to underſtand it fully.

The diſtance from PR, to the ſecond diviſion below it, anſwereth to two chains.

The diſtance from PR to the eighth diviſion upward, being taken (with compaſſes) upon the firſt line of the eleven from P to 8, anſwereth to 80 links.

Conſequently the extent of the compaſſes from the ſecond grand diviſion below P, to the eighth of the leſs diviſions upward, is proportionable to 2 chains 80 links.

The diſtance from PR to the firſt diagonal being taken upon the parallel line, noted with 9 above, anſwereth to 9 links: where note, that the firſt diagonal is not that which is noted with 1, but that which is drawn from the point P.

The diſtance upon the ſame line from PR to the diagonal that is marked with 7, is anſwerable to 79 links.

The extent of the compaſſes from the bottom of the figure upon the ſame line to the ſame diagonal, anſwereth to 3 chains 79 links.

In ſhort, whole chains may be meaſured upon any line from PR, to the grand diviſion noted with the given number, decads alone, or chains and decads upon the firſt line of the eleven where the diagonals begin. Links alone, decads with links, and chains and decads with links, always upon that line upon which the number of the odd links ſtand at the head of the ſcale.

N. B. Theſe directions will as well fit, if half an inch be only allowed for a chain, and conſequently all the diagonals drawn within that extent, as is uſual upon the other end of the ſame rule, the grand diviſion for chains going the contrary way, and noted with numeral figures in order. It is therefore proper when you furniſh yourſelf with ſcales, to have diagonal ſcales of both dimenſions on the fore-ſide of your rule, and upon the back-ſide many plain ſcales of equal parts, with a line of chords.

How to caſt up the content of a figure, the lines being given in chains and links.

Having deſcribed theſe plain inſtruments, and in ſome meaſure ſhewed the uſe of them in ſeveral inſtances, it were very proper in the next place to teach their joint uſe in meaſuring and protracting; but becauſe we would have our young ſurveyor, before we take him into the field, able to perform his whole work together, we intend to ſhew him,

1. How he ought to make his computations; 2. The grounds or principles that will juſtify him in ſo doing.

For the firſt, take theſe rules:

1. Put down your length and breadth of ſquares and oblongs, and your baſe and half perpendicular of triangles directly under one another, expreſſed by chains and links with a prick betwixt them, as was taught before.

2. If the odd links were under ten, put a cypher before the numeral figure expreſſing them, (as there alſo was ſhewed) and if there be no odd links, but all even chains, put two cyphers after the prick.

3. Multiply length by breadth, and baſe by the half perpendicular, according to the rules for finding the content of figures.

4. From their product cut off five figures, accounting cyphers alſo for ſuch, reckoned from the right-hand backward, with a daſh of your pen, ſo ſhall thoſe to the left hand ſignify acres.

5. If thoſe five cut off were not all cyphers, multiply them by four, and cutting off five towards the right hand again, the reſt will be roods or quarters.

6. If amongſt theſe five figures towards the right-hand that were cut off at the ſecond multiplication, there be any figures beſides cyphers, multiply all the five by forty, and cutting off five again by a daſh of your pen,

pen, thoſe on the left hand ſignify ſquare perches, poles, or roods.

A few examples will make all plain.

Queſt. 1. *What is the content of a ſquare, whoſe ſides are every one of them 7 chains, 25 links?*

Length 7. 25.
Breadth 7. 25.

3625
1450
5075

5|25625
4

1|02500
40

1|00000

Anſ. 5 acres, 1 rood, and 1 perch, as here appears.

Queſt. 2. *In a long ſquare whoſe length is 14 chains, and the breadth 6 chains 5 links, what is contained?*

Length 14.00
Breadth 6.05

7000
84000

8|47000
4

1|88000
40

35|20008

Anſw. 8 acres, 1 rood, and 35 perches, as the work makes it evident.

Queſt. 3. *In a triangle, whoſe baſe is 3 chains, and half the perpendicular 98 links, what is the content?*

The baſe 3.00
Half perpend. 0.98

2400
2700

|29400
4

1|17600
40

7|04000

Anſw. 0 acres, 1 rood, 7 perches.

There are other ways of computation by ſcales, tables, &c. But that this is demonſtrative, will appear by the following ſteps.

1. It is evident, that in this way of multiplication, the product is ſquare links; for every chain being 100 links, it is all one to multiply 7.25 by 7.25, or 725 by 725 without pricks; for the pricks ſignify ſomething as to conceptions, but nothing at all in operation. The product therefore of the firſt example was really 525625 links.

2. Every chain being 4 perches long, it follows, that 5 chains, or 20 perches, in length, and 2 chains, or 8 perches, in breadth, make an acre, or 160 ſquare perches; for 20 being multiplied by 8, gives 160.

3. From hence it plainly follows that there are exactly 100000 ſquare links in an acre; for 5 chains multiplied by 2, is the ſame with 500 links by 200, which makes 100000. And he does not deſerve the name of an arithmetician, that is ignorant of this old plain rule, when the diviſor conſiſts of 1 and cyphers, as 10, 100, 1000, 10000, 100000, &c. cut off from the right hand ſo many figures of the dividend as the diviſor hath cyphers, accounting them the remainder; ſo ſhall the reſt on the left ſide be the quotient. It is plain then that 525625 ſquare links, make 5 acres, and 25625 ſquare links over.

Thus we have made it clear to a very ordinary capacity, that as far as concern acres, the rules for computation are good. Now for roods and perches, though it might be ſufficient to mention that known rule in decimal arithmetick, multiplying decimal fractions by known parts, gives thoſe known parts in integers, due regard being had to the ſeparation, we ſhall proceed thus: if 25625 ſquare links, which remain above an acre, contain any quarter or quarters of an acre, then, if they be multiplied by 4, and divided by 100000, that is, five cut off from the product, they will contain ſo many acres as now they do quarters, or roods, for any number of quarters multiplied by 4, muſt needs produce the like number of units or integers, and the diviſion only reduce them into the right denomination. Now, 25625 being multiplied by 4, and five figures being cut off from the product, the reſult is, 1|02500, that is, an acre and above; which ſhews it was above a quarter before it was multiplied by 4.

And to find how much, that is, how many ſquare perches are contained in this laſt remainder, you muſt conſider this 2500, not as ſquare links remaining above the rood or quarter, but as four parts or quarters of ſquare links, or, which is all one, as the true number of ſquare links multiplied by 4, and conſequently being multiplied by 40, the fourth part of ſquare perches in an acre, it muſt as often contain 100000 ſquare links, or an acre, as the quarter of this number 2500, viz. 625, ſignifying ſquare links, containing ſquare perches; and ſo, for 100000 divided by 160, the number of perches in an acre, gives 625, anſwering to one perch; and 2500 multiplied by 40, gives 100000, or one acre, the five cyphers being cut off.

How

How to meaſure a cloſe, or parcel of land, and to protract it, and give up the content.

Hitherto we have been like children learning to ſpell, now let us ſet our ſyllables together: that is, let us make uſe of the inſtructions before given to meaſure a piece of land, to plot it, and to caſt up the content.

All cloſes, or parcels of land, are either ſuch as need not be plotted for finding their true meaſure, but the chain alone doth the work; or ſuch as cannot be conveniently meaſured without plotting or protraction.

Of the firſt ſort are the ſquare and long ſquare, known before-hand to be ſuch, or found ſo to be by ſuch inſtruments as are not yet deſcribed, or by meaſuring all the ſides and diagonals. Theſe ſquares and long ſquares, need no protracting; for you need only to multiply the chains and links of the length, by the chains and links of the breadth, and ſo proceed as in the firſt and ſecond examples: but all others, whether triangles or triangulate, are to be protracted. We ſhall give examples therefore in the three ſorts of figures, triangular, quadrangular, and multangular.

But before we proceed to particular inſtances, let the young practitioner remember,

1. To begin at ſome notable angle of the field where there is ſome houſe, gate, ſtile, well, or the like; or if there be none, then to dig up a clod, drive down a ſtake, or at leaſt, to obſerve what quarter of the heavens it pointeth towards, whether eaſt, weſt, north, or ſouth, and on your paper mark it with the letter A, or any other.

2. To go parallel to the ſide of the field, if pits, buſhes, or the like, hinder not, and if they do, to allow for it, accuſtoming yourſelf to go either with your left hand towards the hedges, walls, or pales; or with your right hand towards them: and when you go contrary to your uſual cuſtom, note it on your paper by ſome mark known to yourſelf.

3. To ſet down the chains and links of every ſide as you meaſure them, and not truſt your memory. A black lead pen will be very proper for this purpoſe.

4. To take care, if you have more ſcales than one upon your rule, leſt you confound yourſelf by taking lines off of ſeveral ſcales, or meaſuring perpendiculars upon wrong ones; for every line of the ſame figure muſt be made by the ſame ſcale, and the perpendiculars meaſured by it.

5. To make uſe of a ſcale of larger diviſions when you meaſure ſmall cloſes, and of ſmaller when you meaſure great ones.

6. To make your lines and points where angles meet, ſmall, pure, and neat.

7. To ſet on your chains and links at twice, when any line is too long for your ſcale.

Theſe things being premiſed, proceed thus:

I. Suppoſe a triangular field is to be meaſured with the chain, beginning at the eaſtern angle A, Fig. 15. and find the ſides in their order and meaſure to be ſeverally thus; 2.29, 3.45, 4.07.

Making uſe of the leſs diagonal ſcale, becauſe the other would make the figure too large, otherwiſe it were more proper for ſo ſmall a cloſe, with your compaſſes to take off the ſcale 4 chains and 7 links, and ſetting them from A to C, draw that line for the baſe, becauſe the longeſt of the three; then take 2 chains 29 links off the ſame ſcale, and ſet them in the eaſtern point A, and turning the looſe foot of the compaſſes above the line A C, deſcribe, at that diſtance 2.29, the arch E E.

Next taking with your compaſſes upon the ſame ſcale the extent of 3 chains 45 links, place one foot in the point C, and with the other make the arch F F, interſecting the former in the point B; and drawing the lines A B and B C, the triangle A B C is the plot of the triangular field meaſured.

But before you can give the content, you muſt find the length of the perpendicular, which is done by ſetting one foot of the compaſſes in B, and extending the other to the baſe A C, ſo as it touch it, and paſs not over it, for then the length of the perpendicular is between the points of the compaſſes, and being applied to the ſame ſcale by which the triangle A B C was made, it appears to be 1 chain 42 links. With the half whereof multiply 4.07, the length of the baſe, the content appears to be 0 acres, 1 rood, 6 perches.

The baſe	4.07
Half perpend.	0.71
	407
	2849
	28897
	4
	1|15588
	40
	6|23520

II. Suppoſe you were to meaſure a quadrangular or four-cornered field, begin as before at ſome remarkable angle; and going round the cloſe, find the ſides to be 9.04, 6.72. 8.46, 7.28, and the diagonal from that remarkable angle to the oppoſite angle to be 10.02; we begin to protract it thus:

Fig. 16. Having by the help of your ſcale and compaſſes drawn the diagonal 10.02, from the remarkable angle A to C, the oppoſite angle, make a triangle of it, and the firſt and ſecond ſides 9.04 and 672, and another after the ſame method of that diagonal, and the third and fourth ſides 8.46 and 7.28, ſo you have the trapezium A B C D.

Then by the help of your ſcale and compaſſes, you find the perpendicular of the triangle A B C to be 6.02, and of the other, viz. C D A 6.01, which added, are 12.03, whereof the half ſum is 6.01; by which, multiplying the baſe 10.02, the content of the field will be 6 acres, 0 roods, 3 perches.

The baſe	10.02
Half perpend.	6.01
	1002
	60120
	6|02202
	4
	1|08808
	40
	3|52320

Before

Before we paſs any farther, let it be remembered,

1. Any quadrangular cloſe, or parcel of ground whatſoever, having right lines, may be thus meaſured, protracted, and computed.

2. The odd meaſure above perches, is not valuable here, nor in the former computations, being always under a ſquare perch; but in multangulars, where there be many remainders, they muſt be ſummed up, and the perches contained in them added to the content before found.

3. This laſt, and the following figures, are made, that they might not be too large, by a ſcale of 400 in an inch, *i. e.* by the leſs diagonal ſcale, each chain and link being counted two.

III. Fig. 17. If this multangular figure be conceived to repreſent a cloſe of ſeven ſides, which is to be meaſured, begin at the remarkable angle A, and going round the cloſe, find the ſides will be 3.11, 2.49, 2.47, 1.77, 4.11, 2.29, 4.37.

Then meaſure the four diagonals, BD, DF, FB, and BG, in the order you will find them to be 3.45, 4.97, 4.13, and 4.36, which is as ſhort a way as can be taken, to prevent unneceſſary walks.

But when you come to protract by the help of your ſcale and compaſſes, firſt make the triangle BCD of the firſt diagonal, and the ſecond and third ſides. Then the triangle DEF upon the ſecond diagonal, and fourth and fifth ſides; and upon the ſame diagonal, as a common baſe, the triangle BDF of the firſt, ſecond, and third diagonals.

Next of the ſame third diagonal, together with the 4th and 6th ſides, make the triangle BFG, and upon the fourth diagonal, as upon a common baſe with the firſt and laſt ſides, the triangle ABG. So is the whole cloſe plotted.

And now it ſtands viſibly reduced into two trapezias ABFG and BDEF, together with the triangle BCD, which we ſhall not now caſt up, having ſo often ſhewn how ſuch work is to be done.

But it muſt be acknowledged that this method of plotting parcels of land that have many angles, requires not only more care and pains, but greater ſkill and memory, than to draw diagonals upon paper, when the plot is already taken by the plain table, or other ſtanding inſtrument. We ſhall therefore, to help our young practitioner in this caſe, advertiſe him of two eaſy ways to help himſelf, ſo as to be out of danger of miſtakes.

One way is, to divide the multangular field into two or more parts, as the laſt might have been by the diagonal BF; then might each part have been meaſured ſeverally, as if they had been ſeparated by a pale, or were ſundry men's lands parted by a boundary.

Another way that much helps both the underſtanding and memory is, to draw a rude draught of the figure of the land you intend to meaſure, not only as to the ſides, but alſo neceſſary diagonals. Then meaſuring the lines upon the ground correſpondent to thoſe on the paper, ſet the lines as you meaſure them upon the lines of the draught, as if it were the true ones, and when you have finiſhed your meaſuring, protract it truly. Such as you ſee here, but it is better larger, will do your buſineſs; for it is not a pin matter how rude or falſe the lines or angles be, reſemblance being all that is deſired.

Concerning the meaſuring of circles, and their parts.

We have hitherto purpoſely abſtained from meddling with the circle, and its parts, that we might lay thoſe things cloſe together without unneceſſary mixtures, that are of greateſt uſe.

It is very rare, if a land meter ever have occaſion to meaſure any field or parcel of land, that will prove either circle, ſemi-circle, quadrant, or ſector. Sometimes indeed there will be a little crook in an old hedge bowing like an arch; but we have never ſeen any offer to meaſure it as a ſegment, but always take it as an angle or angles.

Yet becauſe it may be expected we ſhould ſay ſomewhat of thoſe things, we ſhall briefly do it,

I. To meaſure a circle in the more exact way, is, to ſquare the diameter, and to multiply that ſquare by 7854; ſo ſhall the content be in integers and decimals.

But the more uſual and quick way, (and near enough for any uſe we ſhall make of it) is, to multiply the half of the periphery or circumference by the ſemi-diameter.

In like manner to find the content of a ſemicircle, quadrant, or ſector, made up of ſemi diameters, and arched lines, multiplying the half arch by the ſemi-diameter, gives the content.

Fig. 19. But that which falls out moſt frequently in menſuration, tho' ſeldom much regarded, except where a curious exactneſs is required, is that particular ſort of ſegment which we call a ſection, leſs than a ſemi-circle, ſuch as this figure ABC. And to find the content of it, the center of the circle, whereof this is a ſection, muſt be firſt found, as here at O, from which lines drawn to A and B, make up the ſector AOBC; which being meaſured according to the laſt rule, and from the content thereof, the content of the triangle AOB ſubſtracted, the difference or reſidue is the content of the ſection ABC.

But two queſtions may be here demanded:

1. How may the center be found? 2. How may ſuch a portion of land be truly protracted and computed?

To the firſt we anſwer, that the moſt exact and artificial way, is, by making a mark any where in the arch.

As for example.

At the point C, and then, by a problem known not only to every ſurveyor, but to ordinary carpenters and joiners, for finding the center of a circle, whoſe circumference will paſs through 3 given points that are not in a right line, as ACB, to find the center O. But if you know not how to do it ſo, croſs the line AB in the middle, as here it is done by the perpendicular OC; ſo you may by a few trials find both the due extent of your compaſſes, and the point in the perpendicular that will fit your purpoſe near enough; for if a little error be committed in making up the ſector, the moſt of it goes off again in the ſubſtraction of the triangle.

II. For the latter, you may take this ready courſe: meaſure the length of both your lines, the chord and the arch, and their diſtance at the middle of them both; then, when you come to protract, firſt take the length of your right line from the ſcale, and having laid it down, croſs it in the middle at right angles with a dry line, as in the laſt figure, ſo ſhall it interſect the line AB in the point E; then from the ſame ſcale take the meaſured diſtance between the two lines in the middle, and ſet it upon that dry line from the interſection at E, to the point C. Then, by trials, find a due place in the dry line OEC, and ſuch a diſtance with your compaſſes, that the one foot reſting in that line, the other may deſcribe the arch ACB, and the ſection is protracted.

Con-

Concerning cuſtomary-meaſure, and how it may be reduced to ſtatute-meaſure, & e contra, either by the rule of three, or a more compendious way by multiplication only.

Though the ſtatute-perch or pole is 16 feet and a half, and no more, yet there are poles of larger meaſure uſed in many places, as of 18, 20, 21, 24, and 28 feet, nay, in ſome 22 feet and a half. It were therefore very convenient that our young ſurveyor were furniſhed with a chain fitted to the cuſtomary meaſure of the country where he lives. But becauſe theſe are too large and cumberſome for ſmall cloſes, it is very convenient, inſtead of one chain of 100 links, to make two of 2 poles apiece, each pole divided into 25 links, as that of 100 is; which two half chains may, in meaſuring large fields, be tied together by the loops with pack-thread, or joined by a buttoning key-ring for more ſpeedy diſpatch; but in ſmaller we may uſe the half chain of 50 links, only taking care that we count not half chains for whole ones.

And in theſe caſes where the poles are large, and the cloſes ſmall, it were ſtill more convenient if you had a chain of 2 poles only, divided into 100 links. Only you muſt then take notice, that whereas working by whole chains and links, the firſt multiplication, after five cut off, gives the content in acres and parts. The like work by half chains and half links, will give the content in roods or quarters of acres, and parts of ſuch roods.

But though it is no hard matter, for one that can find out the length of a link by dividing the number of feet in a chain by 100, and provide himſelf of good iron-wire and curtain-rings to make it of, and a ſharp-edged file, and round-noſed plyers to make it with, to be furniſhed with ſuch a chain, yet becauſe every one cannot do this, we ſhall ſhew how you may eaſily, and yet very truly reduce ſtatute-meaſure into cuſtomary, that ſo the chain before deſcribed may do your buſineſs all England over.

Know therefore, for a ground to go upon, that acres bear proportion to one another as the ſquare of their poles; and therefore if you multiply 33, the number of half feet in the ſtatute-pole, by itſelf, which gives 1089, and alſo multiply the number of half feet contained in a pole of that meaſure you would reduce into; in the ſame manner you may, by the rule of three reverſe, obtain your deſire, making to that purpoſe 1089 the firſt number, the ſtatute-meaſure the ſecond, and the ſquared half feet of the pole given the third. As for example: ſuppoſe of a cloſe meaſured by the ſtatute-pole, the length and breadth, and their product be as here represented in the margin. And it is deſired that the content may be caſt up according to the large Cheſhire meaſure of eight yards, or 24 feet to the pole or rod. Then before you cut off any figures, conſider that in the ſtatute-pole are 33 half feet, and in the Cheſhire pole 48; multiply therefore 33 by 33, and 48 by 48, and you will have, 1089 and 2304, which, together with the ſaid product, may be thus placed: 1089, 672693:: 2304, and ſo multiplying 672693 by 1089, and dividing their product, being 732562677, by 2304, the quotient is 317952; from which, if 5 figures towards the right hand be cut off, the content, by this cuſtomary-meaſure of 24 feet to the pole, will be 3 acres, 0 roods, 28 perches, as here appears:

9·33L.
7·21B.
933
1866
6531
prod. 672693

3|17952
4
1|71808
40
28|72320

But if the lines on the land had been meaſured according to that cuſtom of 24 feet to the pole, and the content muſt have been found according to ſtatute-meaſure, then we muſt have multiplied the product by 2304, and have divided that latter product by 1089. And in the ſame method you may proceed in all or any of the reſt. But the truth is, that though this way be very exact, plain, and comprehenſive, ſuiting all the cuſtomary-meaſures before-mentioned without fractions, it is ſomething tedious, except the practitioner knows how to relieve himſelf by a large table of logarithms, which we cannot ſtand here to treat of. Therefore to contract the work a little, take notice, that all the cuſtomary poles being mentioned, ſaving only thoſe of 20 and 28 feet, which we ſuppoſe are ſomewhat rarely uſed, having never heard nor read of them, but in Mr. Holwell; all the reſt are capable of being divided into half yards: and therefore, if inſtead of ſquaring the half feet, you ſquare the half yards of both poles, and work with them, you will attain the ſame end without any regardable difference, the ſmall diverſity that there is, being generally in the uſeleſs remainders, not at all affecting the deſired quotient that gives the anſwer near enough for uſe.

As for example.

If we had ſquared 11 the number of half yards in the ſtatute-pole, which would make 121, and alſo 16 the number of half yards in the Cheſhire-pole, which would make 256, and then multiplied the firſt product 672693 by 121, the ſecond product would have been 81319853, which being divided by 256, the quotient would have been, as before, 317952. And this way is in a manner co-incident with Mr. Holwell's firſt method.

11
11
11
11
121
16
16
96
16
256

Take notice alſo once for all, that whether you uſe either of theſe or the following methods, you need not reduce the particular ſquares, triangles, or trapezia's ſeverally; but ſum up all their products together, and then reduce all at once.

But if you would reduce ſtatute-meaſure into cuſtomary by multiplication only, take notice of this preſent table following.

The content by the ſtatute-pole being multiplied by	.84027	Gives the content by the pole of	18
	.68062		20
	.61734		21½
	.53777		22
	.47265		24
	.34725		28

Feet.

The uſe of this table.

When you have multiplied lengths by breadths, or baſes by half perpendiculars, multiply theſe products by the decimal fractions anſwering to the cuſtomary-meaſure, into which you would reduce ſtatute-meaſure, and from that latter product, firſt cut off five places towards the right hand, as not to be regarded, being only parts of a ſquare

link, then cutting off five more, and proceeding to multiply by 4, and then by 40, as hath been often ſhewn, you will have the content by that cuſtomary-meaſure.

Example.

Suppoſe the length of a cloſe meaſured by Gunter's chain, and multiplied by the breadth meaſured alſo by the ſame, produced 672693 ſquare links; and it is deſired, that the content may be given in Cheſhire meaſure of 24 to the pole; you muſt multiply 672693 by 47265, the decimal fraction anſwering to 24 feet, and from that product, being 31794834645, cut off and caſt away 5 places, and the reſt being 317948, are in the uſual way eaſily reducible into 3 acres, 0 roods, and 28 perches, as here appears, agreeable to what it amounted to in the former method.

3|17948
4
|71792
40
28|71680

But if you meaſured by a chain of cuſtomary-poles, and deſire to know what the content is in ſtatute-meaſure, this following table is for your purpoſe.

Feet.

The content meaſured by the pole of	18	being multiplied by	1.19008	gives the content by the ſtatute-pole.
	20		1.46923	
	21		1.61983	
	22½		1.85950	
	24		2.11570	
	26		2.87970	

To underſtand which, take this example.

Suppoſe the length and breadth of a long ſquare being meaſured by a chain of 24 feet to the pole, and multiplied together, make their product 317952, let this be multiplied by 2.11570, which anſwereth to 24 feet, and the latter product will be 67269104640; from which, if you cut off and caſt away 5 places towards the right-hand, the remainder is 672691; which, in the uſual way, is eaſily reduced to 6 acres, 2 roods, and 36 perches.

6|72691
4
2|90764
40
36|30560

One thing more, and we have done with this buſineſs of reduction. If the content to be reduced, be caſt up into acres, roods, and perches, reduce all into perches, and then in other reſpects work as before, either by the Rule of Three, or by this laſt method of multiplication only. So ſhall you have the content in ſquare perches, according to the meaſure deſired, which you may reduce into acres by dividing them by 160; and if any thing remain, that remainder being divided by 40, will give you the roods in the quotient, and the latter remainder the number of ſquare perches.

For trial of which rules, remember the anſwer of theſe two following queſtions wrought all three ways.

Queſt. 1. *How many acres, roods, and perches according to the pole of* 18 *feet, contained in* 5 *acres,* 3 *roods, and* 11 *perches ſtatute-meaſure?*

Anſ. 4 acres, 3 roods, and 22 perches, as here appears.

How to meaſure a piece of land with any chain of what length ſoever and howſoever divided; even with a cord or cart-rope, being a good expedient when inſtruments are not at hand of a more artificial make.

If you can procure a chain, and find it is not divided as before hath been ſhewn, but into feet or quarters of yards, or any ſuch vulgar diviſions, make no reckoning of the diviſions at all, but meaſure it as exactly as you can find out the true length of the whole chain; and if it fit none of thoſe lengths mentioned before, nor any of their halfs, make it fit by taking off a link or two, or piecing it out with a ſtring; then dividing the length of that chain by 100, or the half of it by 50, find the true length of a link according to our artificial diviſions, and having got a long ſtick or rod, ſet as many of thoſe link-lengths upon it as it will hold; then may you meaſure all the whole chains by your regulated chain, and the odd links of every line by your divided ſtick or rod, as is manifeſt in this example following.

Being far from any inſtrument, and requeſted by a friend to meaſure him a cloſe, you muſt procure a pair of compaſſes, an ordinary carpenter's rule of two feet, divided into inches and quarters, and alſo with a piece of an old chain ſeemingly divided into feet, meaſure it by the rule, and finding it to be 45 feet long, and ſome odd meaſure, piece it out with a pretty ſtrong cord that will not ſtretch much, to 48 feet exactly; then it will ſerve for half a chain of 24 feet to the pole: this 48 multiply by 12, the number of inches in a foot, and that product being 576, divided by 50, the number of links in half a decimal chain, and the quotient is 11 $\frac{66}{100}$ inches, or 11 inches and an half, and a trifle over: dividing therefore a long ſtick throughout into ſuch parts, each containing 11 inches and a half, beſides the breadth of the nicks, you are provided of tools to meaſure lines to a link with exactneſs enough.

In like manner you proceed with a cord or rope, having fitted them to ſome known length or other; and then for protracting, it were eaſy with the compaſſes to make a plain ſcale of a large ſort, either upon paper, or an even piece of wood. This for once may ſerve a man's turn well enough.

Beſides, there is a way of meaſuring the perpendiculars of triangles and trapezias upon the ground itſelf, ſo as to prevent the neceſſity of a ſcale; for if you have a little ſquare with a hole in it to turn upon the head of a little ſtick, which you may fix where you pleaſe, as you are meaſuring the baſe of a triangle, or the diagonal of a trapezium, you may by a very few trials find the place where the one leg will be juſt in the line you are meaſuring, and the other point at the angle from which the perpendicular falls on it, and then the ſpace between your ſtick and that angle truly meaſured, is the perpendicular.

If you have not ſuch a ſquare, a ſquare trencher, or any end of a board that hath one right angle, and two true ſides, will ſupply the want of it.

And we ſhall make bold to add, that this is a good way to meaſure a trapezium, tho' it be protracted afterwards; for by meaſuring the perpendiculars as aforeſaid, and obſerving at how many chains and links end the ſaid perpendiculars meet the common baſe, the whole trapezium may be truly protracted without going about it; this little ſquare competently ſupplying the place of an inſtrument, which is uſually called a croſs or ſquare, made up, as it were, of two ſmall indices, like thoſe for a plain table, but much leſs, with fore-ſights and back-ſights, and cutting one another at right angles put together, and having an hole at the center.

Concerning dividing of land artificially and mechanically.

1. To divide a triangle into any parts required; divide the baſe as the demand imports, then ſhall lines drawn from the points of diviſion to the oppoſite angle, finiſh the diviſion of the triangle.

Example.

Fig. 20. A C, the baſe of the triangle A B C, being divided into 12 equal parts, a line drawn from the angular point B to the point 6, divides the triangle into two equal parts; 2 lines drawn to 4 and 8, divide it into three equal parts; two lines drawn to the points noted with 3, 6, and 9, divide it into four equal parts; and ſo lines drawn to 2, 4, 6, 8, 10, divide it into ſix equal parts.

Alſo it is very obvious, that if the ſame triangle were ſo to be divided, that the one part ſhould be double to the other, a line drawn from B to 4 or 8, doth the work, or if it be required to divide it into two parts, ſo as the one ſhall be triple to the other, a line drawn from B to 3 or 9, compleats the work. So alſo a line from B to 2 or 10, divides it into two parts, whereof the one is quintuple, or five-fold, to the other, and a line from B to 1 or 11, divides it into two parts, whereof the one is 11 times as large as the other.

Farther yet, if it were required this triangle ſhould be ſo divided, that the two parts ſhould in quantity bear proportion, as 5 and 7, a line from B to 5 or 7, will anſwer the intention.

The diviſions will indeed be ſometimes a little more intricate than this, yet not ſuch, but that the ſeeming difficulty may be eaſily overcome by obſerving the following method.

Suppoſe a large triangle of common land to be divided amongſt three tenants, A, B, and C, according to the quantity of their tenements, A, having 19 acres of land to his tenement, B 13, and C 7, the baſe of the triangle being found by meaſure to be 17 chains and 27 links; and the demand is, where the point of the diviſion muſt be placed in the baſe, ſo as lines drawn from thence to the oppoſite angle, ſhall truly limit each man's part.

To anſwer this, let us add 13 and 07 to 19, and they give 39: ſo is the work plainly reduced to the rule of fellowſhip; and therefore to find every man's diſtinct portion, we need only to multiply the baſe by his particular number, and divide that product by 39, the ſum of all their numbers.

38

From theſe operations, it is plain, that if we ſet off from the angular point where the baſe begins, 8 chains, 41 links, and a little above the third part of a link upon the baſe for A, and where that ends, 5 chains and 75 links and 2/3 of a link for B, and conſequently leave between this ſecond diviſion and the other end of the baſe 3 chains and almoſt 10 links for C; lines drawn from thoſe points of diviſion to the oppoſite angle, will give each man his due.

What has been ſaid touching the diviſion of triangles upon their baſes, will, with a little variation, ſerve for the dividing of all ſorts of parallellograms, whether ſquares, long ſquares, rhombus's, or rhomboides; all the difference is, that inſtead of drawing lines from points in the baſe to the oppoſite angle, you muſt draw parallel lines from points in one oppoſite ſide to another, as will be ſufficiently plain by this one inſtance.

Fig. 7. Suppoſe the ſquare figure to repreſent a cloſe of ſix acres, and you are to cut off an acre at the ſide A C; having ſet off the 6th part of the line C D, from C towards D, and alſo from A towards N, a parallel drawn between thoſe points, takes off exactly a 6th part of an acre.

If it be not thought convenient, as in ſome caſes it is not, to cut off a piece ſo long and narrow, you may by the Rule of Three find what other length of any greater breadth will limit an equal quantity to it. Or you may multiply the breadth by 2, 3, or any other, and divide the length by the ſame number that you multiplied the breadth by. Or laſtly, if you ſet out a double proportion that is 2/6 or 1/3, from C towards D, and from the point where it falleth, draw a line to the angle A, you will have a triangle equal to 1/6 of the ſquare A C D N.

But to return to triangles, the moſt ſimple and primitive of all rectilinears, and therefore the moſt conſiderable in this caſe of partition, as giving laws often to the reſt, it may fall out that a triangle muſt be divided, by a line from ſome point in a ſide, ſo as that line may either be parallel to ſome other ſide, or not parallel to any.

Fig.

Fig. 21. Let ABC be a triangle given, and it is required to cut off $\frac{1}{5}$ by a line parallel to AB. First, on the line AC describe the ſemi-circle AEC, whoſe diameter CA divided into five equal parts according to the greater term, and upon three of thoſe parts, the leſſer term, erect the perpendicular DE, which cutteth the arch line in E; than ſet the line from CE from C to F, and from thence draw the line EG parallel to AB; ſo will the triangle CGF contain $\frac{1}{5}$ of the triangle ABC, as was required.

Fig. 22. Now, for the latter caſe, when the line of partition goes not parallel with any ſide, take this example:

Let ABC be a triangle given to be divided into two parts which ſhall bear proportion to one another, as 3 and 2, by a line drawn from the point D in the baſe, or line AC.

From the limited point D, draw a line to the angle B; then divide the baſe AC into five equal parts, and from the third point of the diviſion draw the line to E parallel to BD. Laſtly, from E draw the line ED. So ſhall the trapezium ABED be in content as 3 to 2, to the new triangle DEC.

We ſhall have now done with the diviſion of triangles, when we have added the three following adverti ſements.

1. You muſt be ſure to take very exactly the diſtance of every point, where a dividing line cutteth any ſide, to one of the ends of the ſame ſide, as in this laſt figure, the diſtances BE and AD; which diſtances being applied to the ſcale by which the triangle was protracted, will ſhew at how many chains and links end you are to make your dividing line on the field itſelf.

2. The proportions by which you are to divide, are not always ſo formally given as in the former examples, but are ſometimes to be found out by arithmetical working, as in this caſe.

Suppoſe a triangular field of 6 acres, 2 roods, and 31 perches, muſt be divided ſo as the one of the two parts ſhall be four acres, 3 roods, and 5 perches, and the other, conſequently, 1 acre, 3 roods, and 26 perches; reduce both meaſures into perches, and the one will be 705, and the other 306. Their ſum is 1701, which, by their common meaſure, being reduced into their loweſt terms of proportion in whole numbers, will be 5, 2, and 7, which ſhews that the triangle being divided into 7 equal parts, the one muſt have 5 of thoſe 7 parts, and the other 2. And obſerve, that it will be ſufficient to find the common meaſure between the ſum of your terms, and either of the terms; the method whereof is ſhewn in every arithmetic-book for reducing fractions into their loweſt terms.

But the reader may multiply either of the parts; as ſuppoſe 765, by the length of the baſe, which we will ſuppoſe to be 8 chains and 75 links, or 87 links; and that product divided by 1071, the content of the whole cloſe in perches, gives the rule of three direct, 625 links, or 6 chains and 1 pole, the true diſtance from either end of the baſe, that his mind or occaſions may direct him to begin with, to the point of diviſion; for the diviſion muſt be not only for proportion or quantity, but alſo as to poſition or ſituation of parts upon the paper, as it is required to be on the ground.

3. In theſe and all other diviſions of land, where a ſtrict proportion in quantity is to be obſerved, you muſt have reſpect to the rules given hereafter concerning meaſuring of uneven ground, eſpecially if one part prove much more uneven than another: and if there be any uſeful pond, or well to draw your line of diviſions through it; but if it be an uſeleſs pond, lake, or puddle; or if there be any boggy or barren ground, that muſt be caſt out in the diviſions, meaſure that firſt, and ſubſtract it from the content of the whole cloſe, and then lay the juſt proportion of the remainder on that ſide that is free from it, that the other may have its juſt part alſo, beſides that which is uſeleſs.

What hath been ſaid, with an ordinary meaſure of diſcretion, may ſufficiently inſtruct a young artiſt to divide triangles, parallellograms, and regular polygonials, in an artificial way; but becauſe many cloſes and open grounds are trapezias, and many irregular polygons, and even thoſe that are regular enough, may fall under an irregular diviſion, in regard of the quality of the land, woods upon it, or quarries in it, or the conveniencies of ways, currents of water, ſituation in reſpect of adjacent lands, &c. we ſhall propoſe a method, which though it hath ſomewhat of the mechanick in it, will be ſingularly uſeful in ſuch caſes.

Let ABCD be a trapezium to be divided betwixt a young heir and his mother, ſo as his part may be double to her's. Having by the diagonal BC divided it into two triangles, you will find the content of the triangle ABC to be 138550 ſquare links, and the triangle BCD to contain 103468, in all 242018 ſquare links, which, if reduced, as hath been formerly taught, would amount to 2 acres, 1 rood, and 27 perches.

But for the preſent work, they are in a better order already. Dividing then 242018 into three parts, each of them is 80676 and $\frac{2}{3}$, two therefore of thoſe third parts muſt contain 161353 and $\frac{1}{3}$, which $\frac{1}{3}$ being inconſiderable, regard them not.

Then if you reſolve to lay out the double part towards the line BD, ſtrike at adventures the line EF, and meaſuring the trapezium bounded by that line, and the oppoſite ſide BD, together with the interjacent parts of the lines AB and CD, which you will find to contain 119140 ſquare links; but becauſe it ſhould have been 161353, ſubſtract 119140, out of 161353, and their difference is 42213, and perceiving that the lines AB and CD are very near parallel, and finding their diſtance where they are cut by the line EF, to be 326 links, or 3 chains and 26 links, divide 42213 by 326, and the quotient is 129 links, and almoſt half, at which diſtance draw the line GH parallel to EF; ſo ſhall the trapezium GBDH be the heir's part.

Another way whereby the ſame thing may be performed is this. Finding the triangle ABC to contain 138650 ſquare links, ſubſtract it out of the heir's part, viz. 161353, the difference 22803, ſhews how many ſquare links muſt be taken out of the triangle BCD, and added to the triangle ABC; which to perform with all neceſſary exactneſs, ſuppoſe the ſide or line BD to be the baſe, which by meaſure proves to be 344 links, or 3 chains and 44 links. Say by the Rule of Three direct, if the whole content of the leſſer triangle, viz. 103468, give 344; what ſhall 22803 give? So will the reſult be 75 links, and ſomewhat more than $\frac{4}{7}$, or a link, for 22803 multiplied by 344, gives 7844232, which being divided by 103468, the quotient is $75\frac{15413268}{103468}$; or according to decimal diviſion, 75,8131, which is ſomewhat more than 75 links and $\frac{4}{7}$, wherefore extending your compaſſes upon the ſcale to almoſt 76 links, ſet that diſtance upon the line BD, from B to I, and draw the line CI: ſo ſhall the trapezium ABIC be double to the triangle ICD, within ſo ſmall a matter as is not worth regarding, though the land were a rich meadow.

We hope it will be unneceſſary to tell any man of ſenſe, that if he pleaſe he may begin with the leſs part, and take out

but that; or if there be many partners, he may divide betwixt any one and all the reſt, putting their parts together, and then by the ſame method ſub-divide amongſt them till each hath his due ſhare; not to ſpend many words in telling him he muſt ſubſtract where he hath, by ſeparating a line at adventures, or by chooſing out a triangle, taken too much, as we added, when we took too little. Nor laſtly, that theſe methods are not only applicable to trapezias, but to any triangular figure whatſoever, whether regular or irregular.

Concerning the boundaries of land, where the lines to be meaſured muſt begin and end.

If there be no agreement between the parties concerned, for if there be, that muſt be obſerved, reaſon and cuſtom are the ſurveyor's guide.

The farmer ſpeaks loudly, that when a piece of arable or meadow-land, is let for a year to be ſown or mown, no more ſhould be meaſured, nor expected to be paid for, either to the letter or workmen, than the plow or ſcythe can go over. So alſo when a parcel of land is let for paſture by meaſure to a farmer, it ſeems very reaſonable, that all, and only ſo much ſhould be meaſured, as is uſeful to that purpoſe.

But commons to be incloſed are uſually meaſured, except it be otherwiſe agreed, to the uttermoſt bounds of every man's particular proportion, without any allowance for ditch or fence, every man being to make them upon his own of what breadth he pleaſes. Nor is this unreaſonable, for it is as good for one as another, and the rate paid to the lord is uſually very little, ſometimes nothing.

It is alſo very uſual in meaſuring betwixt lord and tenant, in caſe of leaſes for lives, and long terms of years, to extend the lines to the utmoſt bounds of the tenant's claim, taking in the very walls, hedges, and ditches: but this is accounted very hard, and oft proves very unequal among the tenants of a lordſhip, ſome being forced to make much more waſte of their ground this way, than others that hold as much or more. But where the cuſtom obtains, the ſurveyor muſt obſerve it; for it is others work to appoint what muſt be meaſured, and his only to meaſure truly what is ſo appointed. A good landlord may, and will be apt, to conſider it in his rates, and a bad one it is like will be tenacious of a cuſtom to his own advantage.

Laſtly, in caſe of a ſale by meaſure at a rate agreed upon per acre, no boundaries being ſpecified in the bargain, the rule is to extend the lines to the quick wood-row, that is, to the place where the quick wood actually groweth, or where, according to cuſtom, it ought to be ſet.

Containing a deſcription of the plain table, the protractor, and lines of chords.

Though what hath been already ſaid, may competently ſuffice to inſtruct the young artiſt in meaſuring a cloſe of land, yet to advance him a degree higher in uſeful knowledge, we ſhall take occaſion to deſcribe unto him the plain table, which conſiſts of ſeveral parts.

1. The table itſelf, which is a parallellogram of wood fourteen inches and a half long, and eleven inches broad, or thereabouts, and for neceſſity may be made by an ordinary country workman of one board; but for neatneſs, convenience of carriage, and freedom from warping, it is uſually made of three little boards joined together ſide ways, with a ledge at each end to hold them faſt together, and upon the middle board a ſocket of braſs fixed with three ſcrews, and with a fourth to be faſtened on the head of a three legged ſtaff; of which anon.

2. A frame of wood fixed to it, ſo as a ſheet of paper being laid on the table, the frame being forced down upon it, ſqueezeth in all the edges, and makes it lie firm and even, ſo as a plot may be very conveniently drawn upon it. This is uſually made with joints for more eaſy carriage, but a plain one may ſuffice. Upon one ſide of this frame ſhould be equal diviſions, for drawing parallel lines both long-wiſe and croſs-wiſe, as occaſion may require, over your paper, and on the other ſide the 360 degrees of a circle projected from a center of braſs conveniently placed in the table.

3. A box with a needle and card, to be fixed with two ſcrews to the table, very uſeful for placing the inſtrument in the ſame poſition upon every remove.

4. A three-legged ſtaff to ſupport it, the head being made ſo as to fill the ſocket of the table, yet ſo as the table may be eaſily turned round upon it, when it is not fixed by the ſcrew.

5. An index, which is a large ruler of wood, or rather braſs, at the leaſt ſixteen inches long and two inches broad, and ſo thick as to make it ſtrong and firm, having a ſloped edge, by which we draw the lines, called uſually the fiducial edge, and two ſights of one height, whereof the one hath a ſlit above, and a thread below, and the other a thread above, and a ſlit below, ſo ſet in the ruler, as to be perfectly of the ſame diſtance from the fiducial edge. Upon this index it is uſual to have many ſcales of equal parts, and there might be a diagonal ſcale if the inſtrument-maker pleaſe, and lines of chords of ſundry lengths; but if you have ſuch a ſcale as before deſcribed, you need not to have them here.

The protractor is an inſtrument ſo well known and ſo eaſy to be made and procured, that we ſhall be very brief in the deſcription of it. As it is uſually made, it conſiſts of two parts, a ſcale and a ſemi-circle, but the ſcale is no neceſſary part of it, but ſerving, if you be not otherwiſe provided, for other uſes before-mentioned in the caſe of plain ſcales.

But the ſemi-circle is more eſſential, and it may be made of braſs, or other metal of any convenient ſize, as four inches, more or leſs, for the ſtrait ſide, this ſemi-circle being bounded as all others are by two lines, the one right or ſtrait, the other circular.

The right line is divided in the preciſe middle, by a point which is in the center, upon which the circular boundary is drawn, and two other arches concentrical with it.

The center, when the ſemi-circle goes alone without the ſcale, ſhould be guarded with two little lips, on each ſide one, or a little loop, for more convenient turning of the inſtrument about upon a pin fixed in a paper.

The arched or circular edge is divided into 180 degrees, or equal parts, numbered by tens, upon the upper concentrick arch from 0 to 180, and in the lower from 180 to 360. So that by applying the ſtrait edge of the protractor twice to any line, keeping the center right upon a pin fixed in the line, that is, with the ſemi-circle firſt above it, and then below it, contrarily, you may draw a whole circle by the guidance of the arch, or ſet out any number of degrees, as will appear more plainly hereafter.

A line of chords is a line divided into 90 unequal parts, whereof 60, and the radius upon which the circle was drawn, are equal, and the diviſions upon that line are equal to the next extent in a right line, of ſo many degrees from the beginning of the quadrant, as anſwer thereunto.

When lines of chords are cut upon wood, it is both uſual and neceſſary that there be two ſtuds of braſs, the one at the beginning, and the other at 60 degrees, with little holes for the feet of the compaſſes, when you take the extent of the radius, to preſerve the line from being wounded by the compaſſes; and being thus fenced, it will for need do the work of a protractor, but not altogether ſo commodiouſly.

How to take the true plot of a field by the plain table, upon the paper that covers it, at one or more ſtations.

There are three ways or methods for doing this work, two more uſual and ordinary, the third more unuſual and extraordinary, though now pretty well known to moſt ſurveyors, and in late books publiſhed. The firſt performs the work by meaſuring every line from the inſtrument to every angle, and is a very ſure ſubſtantial way where it can be done, as it ordinarily may in moſt cloſes.

The ſecond doth it by meaſuring only the ſtation or the diſtances, and is very quick, but not ſure and exact as the other; yet if managed by a ſkilful artiſt, that knows how to plant his inſtrument, ſo as to avoid making acute angles unneceſſarily, it will come near enough the matter in many places; as in meaſuring for workmen, that take the mowing or reaping the fields by the acre, or when tythes are let at a ſmall value per acre, as in poor barren pariſhes they uſually are.

The third is the way of circulation or perambulation, the inſtrument being oft to be planted, and the plot to be meaſured about; by which not only difficult cloſes, but even the thickeſt woods, yea, bogs, meres, and pools of water, may be plotted, which by neither of the other methods can be performed.

In all theſe methods, two things are to be performed.

1. At every angle where there is no perſpicuous mark already, as a tree, buſh, ſtile, &c. one muſt be placed, as a white paper, or ſuch like; or elſe ſome one muſt go from angle to angle, and remain there as your mark to look at, till you bid him remove to another; only when angles are near you, this labour may be ſpared.

2. Whenever you have occaſion to plant your inſtrument more than once, as it will often fall out in the firſt method, and ever in the two latter, you muſt be ſure it ſtand juſt as it did the firſt time for ſituation; for which your needle, if well touched and hung, will be a good direction, but is not thought ſufficient without back-ſight and fore-ſight. The firſt method is this.

I. When you go about to plot your parcels of land, find ſuch a place in it, if poſſible, from whence you can ſee all the angles, and in that place plant your inſtrument covered with a ſheet of paper, and turning it about till the needle playing at liberty, hang over the flower-de-luce, or any other notable place that you make choice of, ſcrew it faſt. Then chooſing any convenient place in your paper for a center; and to repreſent your ſtation, or place where you fix your inſtrument, make a prick with the ſmall point of your compaſſes; to which prick applying the fiducial edge of the index, which is eaſily done if you keep the point of your compaſſes reſting in it, direct the index, by the ſight to all the angles; and when through the ſlit, or long ſight you ſee the oppoſite thread, cut the mark in the angle, draw a neat dry line along the fiducial edge, to or from the center; then meaſuring from the inſtrument to every angle, ſet the meaſure by a ſcale and compaſſes from the center towards the angle upon the line that points at it, making a prick in the line where the chains and links reckoned from the center truly end; then ſhall lines drawn by a ſtrait line from prick to prick, give you the perfect plot upon your paper, which you may divide, as hath been before ſhewed, into trapezias and triangles, and ſo find the true content. To make which plain, mark this example.

Fig. 24. Suppoſe A B C D E F G H to be a field having planted the plain table, as before directed, at a convenient advantage, ſo as to ſee all the angles, as at I, a prick to repreſent the ſtation in the little circle ⊙ marked with I, upon which laying the fiducial edge of my index, and directing the ſights to all the angles, draw dry lines towards A, and all the reſt of the angles in order from the center; and then meaſuring upon the ground from the inſtrument to the angle A, and find it to be 3. 45, which ſet from the center to the point A, and ſo upon all the reſt, according to their due meaſures, and then black lines drawn from point to point, as from A to B, from B to C, &c. limit the true figure of the field according to the ſcale uſed, viz. of 400 in an inch.

And now before we paſs to farther varieties, let the reader take notice of theſe following things.

1. From henceforth we ſhall forbear to take any notice of the meaſures of lines meaſured from the inſtrument to the ſeveral angles, having ſo often ſhewed how to meaſure by a ſcale.

2. When we ſpeak of meaſuring from or to the inſtrument, we always mean from or to that part of ground that is perpendicularly under the head of the inſtrument where you are to draw your plot, wich will ever be encloſed with the three legs of your ſtaff.

3. That it is uſually the quickeſt way to meaſure firſt from the inſtrument to the firſt angle, and then back from the ſecond angle to the inſtrument, and ſo the reſt in order, ſtill one from the inſtrument, and the other to it.

4. It is no matter at all whether your plain table be placed towards the middle of a field, as was repreſented in this figure, or at an angle, as will appear hereafter.

5. In all workings by this inſtrument, you muſt have a care that the inſtrument be not moved out of its due place, till you have finiſhed the work of the preſent ſtation; for which purpoſe, caſt your eye now and then upon your needle, obſerving whether it continue to hang directly over the ſame point you ſet it at when you began your work, and to rectify your inſtrument if you ſee cauſe. But becauſe all tables have not needles, and where needles are, they are not accounted very accurate, make uſe of the following help.

When you have planted your inſtrument, and made a point or prick in your paper, repreſenting your ſtation, ſet the fiducial edge of your index to it, and turning it ſoftly about till you find one remarkable thing or other upon one ſide of the cloſe, and another on the oppoſite ſide, as you look through the ſights of your index, which we call fore-ſight and back-ſight, draw a remarkable line with ink, or rather with a black-lead pen quite over you paper, which in this figure is repreſented by the black line K L; and then, if you ſuſpect that by any accidental jog, or other caſualty, the

the inſtrument is any thing removed, you may eaſily try, and rectify it by applying the fiducial edge to the ſame line, and making uſe of fore-ſights and back-ſights again upon the ſame marks which you before obſerved upon the oppoſite ſides of the cloſe.

But if there be no convenient place for the placing of your inſtrument, whence you may ſee all the angles of the field, more ſtations muſt be made uſe of thus.

Fig. 25. Let A B C D E F G H I K L M N be a field whoſe angles cannot be all ſeen from any one angle, or other place in it. Plant your inſtrument at the angle A, and if it have a needle, mark what degree of the chord it cuts, or turn about the table on the head of the ſtaff, till the needle hang over ſome remarkable place, as ſuppoſe the flower-de-luce, and ſcrew it faſt; then ſetting up a ſtick with a white paper or cloth on the head of it, where you intend your ſecond ſtation, as here at Q, make a prick or point in your paper, to ſignify the point A upon the paper on the table: to which point you muſt apply the fiducial edge of the index, and when you ſee the white at Q, ſo as looking through the ſlit you ſee the thread cut it, draw the line O P quite through the paper with a black-lead pen, and then keeping the fiducial edge ſtill upon the ſame point, and turning it round by degrees, look at the angles B C D E F L M N, ſtill drawing dry lines with the points of your compaſſes, and ſetting on the meaſures from the ſtation A, to every angle meaſured to or from, as in the laſt example.

Then remove your inſtrument to the place of your ſecond ſtation, having ſet up a mark at A, and laying the fiducial edge to the line O P, turn about the table upon the head of the ſtaff, till through the ſlit of the back-ſight, you ſee the thread cutting the mark at A, and then ſcrew it faſt; ſo will the needle, if a good one, hang directly over the ſame point that it did at the firſt ſtation; but however that be, fore-ſight and back-ſight will do the buſineſs; for which purpoſe it is good to take back-marks as well as fore-marks at every ſtation, as was taught in the example of a ſingle ſtation, only taking notice that the back-mark, when the inſtrument is planted in an angle, muſt needs be out of the field; as ſuppoſe here at O.

Having meaſured the diſtance between the firſt and ſecond ſtation, and finding it to be 7, 10, ſet it upon the line O P, from A to Q; where make another point to repreſent the ſecond ſtation, and turning about the index with the fiducial edge upon that point, and ſo looking through the ſights at the angles G H I K, draw lines towards them on your paper, and having meaſured between every one of thoſe four angles, and the inſtrument, ſet thoſe meaſures, as you did the other, with your ſcale and compaſſes, from Q towards every angle upon his proper line; and then having the drawn black bounding-lines from A to B, from B to C, and ſo round about the cloſe, the protraction is finiſhed.

But here to make this figure yet more advantageous, remember the following advertiſements.

1. Sometimes a ſtation is ſo taken, that you may meaſure towards two angles at once, as here from Q to G and H, in which caſe you are to ſet down the chains and links where the firſt angle falleth, but ſtill be proceeding to the farther angle, cauſing the remainder of the chains at the fore-end to advance beyond the former angles; ſo going on with whole chains ſo far as you can, to which the odd links at the end are to be added.

2. If at any of your ſtations, As ſuppoſe A, you can ſee an angle, for example E, to which you cannot meaſure in a direct line without paſſing the boundaries of your parcel of land given to be meaſured; you may notwithſtanding take in that angle by a ſtrait meaſured line, as we have done, provided it may be lawfully done without treſpaſs, and conveniently without troubleſome paſſing of fences, otherwiſe it muſt be taken from another ſtation.

3. One of your ſtations was here taken at an angle, and the other within the body of the field, to ſhew the variety of working taught by other authors, and that it is no great matter where you make your ſtations, ſo you can ſee the angles; elſe it had been full as convenient to have taken the firſt ſtation alſo within the body of the field, as ſuppoſe at R.

4. Though this figure repreſents to your eye only two ſtations, A and Q, your fancy may multiply them at pleaſure; for ſuppoſe the angle H could not have been ſeen from A to Q, how eaſy had it been to have ſet up a mark at S, and then to have removed the inſtrument thither, obſerving the ſame directions that were given at the removal from A to Q?

II. In the ſecond method the inſtrument is to be planted twice, or oftener, as occaſion requires, the rules for removal of the inſtrument fore-ſight and back-ſight, and meaſuring the diſtance of ſtations, being the ſame as formerly taught; but inſtead of meaſuring to and from every angle, we only view each angle through the ſights from two ſtations, having applied the fiducial edge to the points repreſenting thoſe ſtations, and having drawn lines with the point of your compaſſes, or a protracting needle, the interſections repreſent the angles, from which the boundary-lines may be drawn; ſo is the field protracted. Which that the reader may underſtand, let him note theſe three figures.

Fig. 26, 27, 28. In theſe three figures the angles are marked alphabetically, A B C D E F, &c. and the ſtations by a ſmall point in a ſmall circle numbered, 1, 2, or 1, 2, 3, according to their number and order.

Fig. 26. The firſt of theſe figures repreſents the plotting of a field at two ſtations within it, from both which all the angles may be ſeen.

Fig. 27. The ſecond performs the ſame work by two ſtations taken without the field, by which art a cloſe may be meaſured, though the preſent poſſeſſor will not give us leave to come into it.

Fig. 28. The third ſhews how the work may be performed at three ſtations or more, when two ſuch places cannot be found whence to view all the angles; which laſt having more of difficulty than the two former, though indeed not very much, and the explanation of that will ſufficiently help to the underſtanding of them, we ſhall a little explain the meaning of it in theſe particulars.

1. From the firſt ſtation taken according to the former directions, you ſee the angles A B C D F G K, and accordingly draw lines upon your paper towards them from the point repreſenting that ſtation, by the fiducial edge of your index with the point of your compaſſes.

2. Having removed the inſtrument to the ſecond ſtation, and in ſo doing, obſerved the rules before given, you will thence ſee the angles A B C D E F G H I K, and draw lines upon your paper towards them from the point repreſenting the ſecond ſtation. And now viewing your work, you find upon your paper interſections for the angles A B, D F, G K, but only ſingle lines towards the angles C E H I; therefore,

3. Removing

3. Removing the inſtrument regularly as before, to a third ſtation, you will thence ſee thoſe four angles CEHI, and drawing lines towards them, you will have interſections for them alſo; ſo that having drawn the lines AB BC, &c. from one interſection to another, you have the field perfectly protracted. For theſe bounding-lines from angle to angle, do not only ſignify the boundaries of a piece of land given to be meaſured, limiting the figure or ſhape thereof, and are to that purpoſe given in this and all other ſurveying-books, but alſo are the true diſtance by a ſcale from angle to angle for the plot upon the paper; we mean by the ſame ſcale by which the ſtationary diſtances were laid down upon their own lines. And this holds true in all kinds of true plotting, whether in this method or any other.

III. The third method is that of circulation; and this hath ſeveral varities, according to theſe three following caſes.

1. When the diſtance from angle to angle, without any exception, is meaſured quite round the plot, either within or without.

2. When the diſtance is taken only between ſome more notable angles, and the perpendiculars of the reſt meaſured as you paſs along their baſes, within the plot, proper for plain ſolid ground.

3. When the like is done without the plot, as in caſe of plotting thick woods, meres, pools, bogs, &c.

The firſt of theſe are very eaſy, conſiſting in nothing but planting the inſtrument at every angle, either within or without, as neceſſity and convenience determine it, obſerving the former directions for planting and removing the inſtrument, and alſo for meaſuring the ſtationary lines on the ground, and protracting them on the paper, as is manifeſt in this example.

Fig. 29. Let ABCDEF be a park, pond, or cloſe to be protracted, firſt plant your inſtrument at A, and direct the ſights to a mark in the angle B, drawing a dry line from a convenient point on your paper towards B, on the ground, then having meaſured by your chain the diſtance AB, ſet it by a ſcale upon the correſpondent line from A to B, drawing a black line between them with ink or a lead pen, the extremities whereof are the points A and B on the paper, and the little pricked line that goes beyond B, repreſents the remainder of the dry line drawn at random, as to length, with the point of the compaſſes.

Then ſetting up a mark at A, if there was none before, remove your inſtrument to B, and laying the fiducial edge to the line AB, turn about the inſtrument upon the ſtaff, till through the ſight you perceive the thread cutting the mark at A, and the needle directly over the ſame point, that it was when it was planted at A; and ſo ſcrew it faſt.

Your next work is to lay the fiducial edge to the point B, and direct the ſights to C, drawing a dry line towards it, and ſetting the diſtance BC meaſured by the chain from B to C.

In this manner you are to proceed, ſurrounding the cloſe till you come at laſt to A, where you began, by planting the inſtrument at every angle, uſing the help of backſight and your needle, as at B, and then from the point repreſenting your preſent ſtation, directing the ſight to the next angle, as you did from B to C.

In the ſecond caſe, we do not plant the inſtrument at every angle, but at the more conſiderable, taking in the ſmaller by their perpendiculars from the baſe as we paſs along; of which the following figure may be an inſtance.

Fig. 30. Let ABCDEFGHIKL be a cloſe to be meaſured; by planting the inſtrument only at ACF and K, we have the main ſubſtance of the cloſe in the trapezium ACFK; and for the five ſmall triangles which muſt be added to the trapezium, they may be eaſily protracted by the help of ſuch a little ſquare as was formerly mentioned; for by finding at how many chains and links diſtance from A upon the ground, the perpendicular B *b* falleth upon the line AC; and having meaſured the length of that perpendicular, and taken in between the compaſs-points of the ſcale, we erect a perpendicular of that length at *b*, which is the point upon the paper, where ſo many chains and links determine, as were meaſured upon the ground, from the angles A, to the place where the perpendiculars fell on A *c*, viz. at *b*. Juſt in the ſame manner we raiſe the perpendiculars D *d*, and G *g* I *i*; and then by the help of the perpendiculars, we draw the boundary lines AB, BC, CD, DE, FG, GH, HI, IL, KL, LA: which, together with the line EF between the angles E and F, give the true plot of the field in one large trapezium, and five ſmall triangles ready for caſting up.

The third caſe is like the ſecond, ſo that there needs no new direction concerning it, but to annex one plain diagram; all the difference conſiſting in this, that becauſe we cannot go within it, being ſuppoſed to be ſome pool, bog, or thicket, we muſt of neceſſity go on the out-ſide, and conſequently all the triangles made by inward angles, and their lines upon the meaſured baſes, muſt be excluded, by the boundary-lines, from being any parts of the plot.

Fig. 31. Suppoſing ABCDEFGHIKLMNOP to be a great pool, though here be fifteen angles, plant your table only five times, viz. at AEFH and M, and upon the dry lines AE, FH, HM, and MA, raiſe their perpendiculars in their proper places, and alſo of a right height; by which, and the five ſtationary angles, we may draw the bounding-lines of the plot, excluding all the triangles as foreign to it, they being no reſemblances of any part of the pool, but of land adjacent.

Concerning the plotting of many cloſes together, whether the ground be even or uneven.

Though we do not deſign to make the reader able to ſurvey lordſhips and foreſts, much leſs to draw maps of countries, but to meaſure a parcel of land with truth and judgment; yet we would have him ſo expert, as not to be puzzled, if any ſhould deſire him to draw a true map of a tenement or ſmall demeſne, conſiſting of ſeveral cloſes; for which purpoſe, let him obſerve the following method.

Fig. 32. Suppoſe ABCDEFGHIKLM to be a tenement or ſmall demeſne, divided into fourteen cloſes, to be meaſured and protracted according to their ſeveral ſhapes and ſituation, firſt draw the plot of the whole by the method of circulation, planting your inſtrument either at every angle, or only at the moſt conſiderable either within or without, as you find moſt convenient. This being done, a line from B to M, gives the triangle ABM from the firſt cloſe. In the next place go round the ſecond cloſe beginning at M, then to B, and ſo about to M again: and then for the third cloſe, plant your table at C, and go round

to B, the line B C being protracted already, and ſo of all the reſt, ſtill obſerving which are common lines belonging to ſeveral cloſes, repreſenting the fences, that you may avoid the trouble of meaſuring thoſe lines oftener than once, and lay every part of every cloſe in its due place; and be ſure to keep the inſtrument throughout the whole work to its true poſition by needle, fore-ſight, and back-ſight.

There are divers other ways of doing this work, but none more ſure or plain, eſpecially if the ground be uneven; for in that caſe, if you protract according to the length of lines meaſured from your ſtation to the angles, you will put your cloſes into unproportionable ſhapes, except you reduce hypothenuſal lines to horizontal, by inſtruments, or otherwiſe, which is ſomewhat troubleſome; and the like may be ſaid when you plot with the chain only. Indeed the method of meaſuring only the ſtationary diſtances were very proper for ſetting out the figure of each particular cloſe, provided the diſtance of the ſtations be large, and taken, if poſſible, upon pretty even ground, which ſometimes may be done, though moſt of the cloſe be uneven; and the work ſo ordered, as not to make too acute angles; but becauſe this requires ſkill and care, we adviſe the young artiſt to uſe the circling way, as generally moſt commodious.

It is convenient when you plant your table, that the needle hang juſt over the north-point of the compaſs under it in the box; then may you by the lines overthwart the frame of the table, eaſily draw two lines quite through the plot, cutting one another at right angles, the one pointing at north and ſouth, and the other at eaſt and weſt. And if you mark the two and thirty points of the compaſs upon the place where they interſect, and draw the forms of the houſes, woods, and other remarkable things upon the demeſne, and the courſe of brooks and rivers running through it, it will add to your commendation.

And ſo it will alſo, if you take in ſuch parcels of land bounding it, whether common or peculiar to other men, as will make your plot look handſomely, like a perfect ſquare or oblong. But however that be, you muſt be ſure to protract truly all lanes going into it, or through it, and all cloſes of other men's mixed with it; and alſo all conſiderable ponds, ways, and out-lets, with the names of the cloſes, and quality of the ground, whether meadow, paſture, arable, &c.

Concerning ſhifting of paper.

In work of this kind, it ſometimes happen through the multitude and largeneſs of fields, that one ſheet will not hold your whole plot; in which caſe you may help yourſelf by ſhifting paper, as we call it, thus.

Fig. 33. Let A B C D repreſent the ſheet of paper that covers the table, upon which the plot of the large piece of land E F G H I K ſhould be drawn; having finiſhed your firſt ſtation at E, and the ſecond at F, and find your paper will not receive the line F G, draw it ſo far as it will go to the edge of the paper, and planting your table again at E, proceed in your circulation the contrary way to K and I, where you will find yourſelf again at a loſs for your line I H, but draw it alſo to the edge of the paper; then with the point of your compaſſes ſtriking the line P O parallel to the edge of the paper B C, and the line Q O parallel to D C, and cutting P O in O, throw it aſide for a while, covering the inſtrument with a new one, which mark with the figure (2) for your ſecond ſheet.

Fig 34. Upon which ſecond ſheet, the leading part whereof is repreſented by the three lines meeting in the angular points, A and B, draw P O parallel to A B, the leading edge of the paper, and croſſing it at right angles in the point O, by a parallel to B C, viz. the line O R, being of the ſame diſtance from B C, that Q O in the former ſheet was from D C; then with a rule and a ſharp penknife cut off the end of the firſt ſheet at the line P O, and applying the edge of it to the line P O of the ſecond ſheet, ſo as it may touch that line all along, and the line Q O of the former touch the line O R in the latter, ſo as to make one line with it, draw the lines P G, being the remainder of the line F G, and the line O H, being the remainder of the line I H, and from their extremities the line G H. And if the plot required it, you might proceed on in the ſecond ſheet, and annex a third and a fourth, &c. as there is occaſion.

Theſe ſheets may be pieced together with mouth-glew or fine paſte, applying the edge of the former, as you did upon the table, to the line P O of the latter.

And note here once for all, that when we ſpeak of applying the edge of the paper to a line, we mean the preciſe edge cut by the line P O; but when we ſpeak of drawing lines to the edge of the paper upon the table, we hope none will think us ſo abſurd as to mean the edge that is concealed under the frame, but that the meaning is, that the lines muſt be continued on the paper till they touch the frame.

Concerning the plotting of a town-field, where the ſeveral lands, butts, or doles, are very crooked: with a note concerning hypothenuſal, or ſloping boundaries.

Fig. 35. Suppoſe A B C D E divided, in the manner of a common field, into ſeven parts or doles, belonging to ſeven ſeveral men: firſt, plot the whole, as before hath been taught, then meaſuring from A to B upon the land, note down, as you go along, at how many chains or links, or both, the diviſion is between dole and dole, and accordingly mark them out by the help of ſcale and compaſſes in the line A B on the paper-plot. In the very ſame manner you muſt meaſure and mark out the lines O C and E D; which being done, take the paper from the inſtrument, and laying it before you on a table, with the ſide A E towards you; the compaſſes muſt be ſo opened and placed, as by a few trials they may, that one foot reſting upon the table, the other may paſs through the points of diviſion upon all the three lines, viz. A B, O C, and E D, as in this figure they do.

If the content of any one or more of theſe parts, butts, or doles, be deſired without plotting, it may eaſily be done, without your plain table, thus: take the breadth by your chain at the head, middle, and lower end, and adding theſe numbers together, the third part of their ſum is the equated breadth; by which multiplying the length meaſured down the ridge, or middle, the product gives the content.

But both in this caſe, and that mentioned before, the figure of a plot may be ſomewhat diſordered, not only by the unevenneſs of the ground within, but alſo by the great declivity of the ground where the boundary lines go, either of the whole plot, or particular parcels. For whereas in plotting, every line is preſumed to be horizontal, or level, that it may paſs from angle to angle the ſhorteſt way, and that every

part

part may be duly ſituated, and none thruſt another out of its right place, if it be not level, but falling down towards a valley, or riſing up hill, or compounded of both, a line over ſuch ground, will be falſe as to the plot, and therefore muſt be reduced to a level, and ſo taken off the ſcale, and protracted. For the doing of this, there are ſeveral inſtruments very proper, eſpecially Mr. Rathburn's quadrant upon the head of his peracter, and divers others. But ſuppoſe our country friend to have no other but ſuch as we have already deſcribed, we ſhall ſhew him a plain eaſy way much uſed by practical ſurveyors.

Fig. 36. Suppoſe A B C to be a part of a hill falling within your plot, your boundary line going crookedly from A to B, following the ſurface of the ground. To find the horizontal line, equal to A C, cauſe one to ſtand at the point A, the foot of the hill, and to hold up the end of the chain to a convenient height, and gently aſcending the hill, you muſt draw it level, and make a mark where it toucheth the hill, obſerving the number of links betwixt your aſſiſtant's hand, and that place where he muſt take his ſecond ſtanding, and hold it up as before, and ſo draw it out level again, till it touch the place where he muſt take his third ſtanding, noting the links as before, and ſo proceed, till at laſt, from his fifth ſtanding, you draw the chain level to the higheſt point within your plot, viz. the point B. And now as the pricked lines of this figure put together are evidently equal to the line A C, ſo are the links noted down at every ſtation, when ſummed up, equal to the horizontal line of that part of the hill.

In the very ſame manner, only inverting the order, you may find the horizontal lines going down hill, where that is moſt convenient: and if there be both aſcents and deſcents in one line betwixt two angles, the horizontal lines of both muſt be found and joined together in protraction.

All this concerning declivities of riſing or falling ground, is to be underſtood when they are conſiderable, and a very exact plot required; for ſmall ones, eſpecially when much exactneſs is not expected, are not regardable.

Concerning plotting a piece of ground by the degrees upon the frame of the plain table ſeveral ways, and protracting the ſame.

Hitherto we have ſhewn the uſe of the plain table as ſuch, and our directions have been near as plain as the inſtrument itſelf. We will now ſhew how the plot of a field may be taken by the degrees on the frame by two methods, whereof the one is proper for an ordinary cloſe, where all the angles may be ſeen from one ſtation within it, the other fitting any parcel of land, tho' much larger, whatever be the figure of it.

For the former, take this example.

Fig. 37. Let A B C D E repreſent the figure of a field to be plotted by the plain table in rainy weather, put on the frame without a paper, the graduated ſide upwards, and plant it in ſome convenient place, whence you can ſee all the angles, as at O; then placing the index upon the table, ſo as the fiducial edge may, at the ſame time, go through the center upon the table, and the lines upon the frame of the table cutting it perpendicularly at 360, where the degrees begin and end, and 180, the exact half, turn about the table upon the ſtaff-head, till through the ſights, the ſide marked with 180 being next your eye, ſee the angle A, and then ſcrew it faſt, obſerving where the needle cutteth, and by back ſight cauſing a mark to be ſet up in the line C D at the point F, that the inſtrument may be kept firm from moving, or be rectified if it be moved, during the work. And now the line A O F paſſing upon the land from the angle A, directly under the ſights of the inſtrument to the mark at F, is, as it were, the prime diameter whence the degrees of the angles are to be numbered, and accordingly you muſt mark the angle A in the table hereafter to be exemplified with 360 degrees. Then turning the index with the fiducial edge upon the center, till you ſee the thread cutting the mark at B, the ſaid edge will cut upon the frame at 76 deg. 15 min. which note down for that angle. The like muſt be done, turning the ſights to C D and D, but not to F, for there is no angle, but only a mark in the boundary, and you will find the index to cut for every angle as we have marked them within the pricked circle of the laſt figure, viz. 157 deg. 35 min. for C, 225 deg. 20 min. for D. and 278 deg. and 50 min. for E.

Then meaſure, or cauſe to be ſtrictly meaſured by others, the diſtances betwixt the place where the inſtrument ſtands, and every angle, and you will find them to be as ſet down upon the pricked lines in the little circle, viz. A 4 chains 20 links, B 4 chains 3 links, C 3 chains 84 links, D 5 chains 35 links, E 5 chains 6 links. And now your table both for lines and angles is thus perfected, and the work is ready for protraction within doors.

	D	M	C	L
A	360	00	4	20
B	76	15	4	03
C	157	35	3	84
D	225	20	5	35
E	278	50	6	06

Your judgment will eaſily inform you, that in ſuch weather we ſhall hardly ſtand to make our table neat and formal, but any thing, how rude ſoever, that we can underſtand, doth the feat. A Welſh ſlate with a ſharp ſtile, or for want thereof, a black-lead pen, and a ſmooth end of an hard board like a trencher, is more convenient at ſuch a ſeaſon, than pen, ink, and paper. But of all, we would commend for expedition a red-lead pen, whereby you may mark out every angle neatly with one touch upon the table itſelf, juſt where it toucheth the frame by help of the fiducial edge, and cloſe by it the length of the line from the center to that angle: all which may be eaſily cleared off by a wet ſponge or cloth ſo ſoon as you have protracted.

Fig. 37. Now to protract our obſervation; draw upon a paper the line A F at adventure, ſo it be long enough, and ſtick a pin in it at pleaſure for the center O, upon which place the center of the protractor, ſo as the ſtraight ſide may juſt lie upon the line A F, the limb or arch-ſide being upwards towards B; by help whereof make a prick or point on the paper 76 degrees 15 minutes for B, and at 157 degrees 35 minutes for C, according to the number neareſt to the limb.

Then turning the protractor about on the pin with the arch or limb down towards D and E, till the diameter lie again juſt upon the line A F, number downwards from the right hand towards the left, by that rank of figures that are nearer to the center, beginning 190, 200, &c. and over againſt the places where 225 degrees 20 minutes and 278 degrees 50 minutes fall, prick the paper at the ſide of the limb, and through thoſe four points draw ſo many ſeveral lines, upon which, and alſo upon the line A O,

mark out by what points the true meaſure of every line, by a ſcale, from the center, and from thoſe points drawing the lines AB, BC, CD, DE, and EA, you have the true plot of the field.

Having proceeded in the field as before, and made your table for lines and angles, or done that which is equivalent by a red-lead pen, draw the line AF, and having extended the compaſſes to the radius, or 60 degrees, on a line of chords, ſet one foot towards the middle of the line AF, and with the other deſcribe a circle like that in this figure of a five angled field, but much larger, according to the length of the radius: then extending the compaſſes from the beginning of the line, to 76 degrees 15 minutes, ſet one foot in the interſection of the circle by the line A, and with the other foot make a mark in the circumference of the circle upwards, towards the right hand, and through it draw the dry line BO.

In the next place ſubſtract the angle 76. 15 from 157. 35, where the index cut for the angle C, and there remains 81 degrees 20 minutes, which take off the line as before, and ſet it upon the circumference from the interſection by BO, toward the end of the diameter marked with F, and through the point where it falls, draw the dry line CO.

In like manner ſubſtract 157 degrees 35 minutes from 225 degrees 20 minutes, and the difference is 67 degrees 45 minutes, which ſet from the interſection by the line CO, downwards paſt the prime diameter AF, and through the point where it falleth, draw the line DO.

Laſtly, having ſubſtracted 225 degrees 20 minutes from 278 degrees 50 minutes, there remains 53 degrees 30 minutes, which muſt be ſet downward towards the left-hand from the interſection by DO; and through the point where that falleth, draw the line EO. And now having ſet the particular meaſures upon every line, and drawn the boundary lines, as you muſt have done if you had uſed a protractor, the plot is finiſhed.

But for better aſſurance that you have done your work well, take the meaſure of the remaining angle AOE upon its proper arch, viz. from the interſection of the circumference by AF, to the interſection by EO, and applying it to the line of chords, you will find it to be 81 degrees 10 minutes, as it ought to be, for it ſhould be the complement of 276 degrees 50 minutes to 360.

And for farther ſatisfaction, ſum up the degrees and minutes of all the five angles, which for plainneſs-ſake we have noted in every one of them on the out-ſide of the circle in the figure ſo often referred to, and their ſum is 360, as it ought to be.	76. 15 81. 20 67. 45 53. 30 81. 10
	360.000

The reader may now expect that we ſhould teach him how to take a plot at two or more ſtations, when all the angles cannot be ſeen from one: but becauſe this is ſo eaſy from the principles already laid down, to any that is ingenious, and in part rendered unneceſſary by the method preſently following, we ſhall only give this general hint.

When you have from one ſtation taken in all the angles you can ſee from thence, and then are to remove to your ſecond ſtation, do juſt as you would do if the table were covered with a paper; only it is at your choice, whether you would guide yourſelf for back-ſight by a line that may be rubbed off, drawn upon the table itſelf, from the center to the degrees, on the frame along the fiducial edge, or by noting only what degrees it cuts on either ſide of the center, the edge paſſing through it, that by the help thereof and the needle, the inſtrument may be placed in the ſame line and ſituation as before, for taking in the reſt of the angles, if it can be; if not, another ſtation muſt be taken after the ſame manner.

Fig. 38. Let ABCDE be the figure of a field to be plotted, the weather being bad; ſend your aſſiſtants to find the length of every ſide, beginning at A, who return you ſuch an account of every ſide, in chains and links, as are noted upon the figure, and in the table following, viz. AB 3 chains 73 links, BC 4 chains 91 links, &c. In the mean time you are to find the angles; in order to which plant the inſtrument at B, and laying the index on the center look at C, and find the index cutting 10 degrees 15 minutes, and looking at A, it cuts 126 degrees 45 minutes; out of which, if you ſubſtract 10 degrees 15 minutes, there remains 116 degrees 30 minutes for the angle A; but becauſe it will not be ſo convenient to ſubſtract there, you may ſet them down thus: B $\begin{matrix} A & 126.\ 45 \\ C & 10.\ 15 \end{matrix}$ the meaning whereof is, that B notes the angle, and CA the lines meeting there, cutting ſuch degrees on the frame; and the reaſon why A is ſet above, is for more ready ſubſtracting afterwards; then removing to the angle C, and thence looking at B and D, you will find the index is cut as it is here expreſſed, C $\begin{matrix} B & 153.\ 10. \\ D & 15.\ 40. \end{matrix}$

In like manner at D thus, D $\begin{matrix} C & 96.\ 05. \\ E & 28.\ 50. \end{matrix}$

At E thus, E $\begin{matrix} D & 141.\ 20. \\ A & 11.\ 45. \end{matrix}$

And laſtly, at A thus, A $\begin{matrix} E & 98.\ 30 \\ B & 9.\ 20 \end{matrix}$

This being done, you may retire under covert, and by ſubſtraction find 116 degrees 30 minutes for the angle B, 137 degrees 30 minutes for C, 67 degrees 15 minutes for D, 129 degrees 35 minutes for E, and 89 degrees 10 minutes for A, as you will find them on the figure, and in this table, together with the length of the lines.

An.	D.	M.	Side.	Ch.	L.
A	89	10	AB	3	73
B	116	30	BC	1	91
C	137	30	CD	4	88
D	67	15	DE	9	64
E	129	35	EF	2	29

Note, that there is a way to find the angles without ſubſtraction, if at every ſtation you lay the fiducial edge over the center, and the diviſions 180 and 360, turning about the head of the inſtrument upon the ſtaff, till through the ſights you ſee one of the neighbouring angles, for the index turned upon the center to the other angle, will give you the quantity of the angle you are at, but this exact planting at every angle is more tedious than the other, and therefore not ſo fit for wet weather. But now to protract this plot:

Firſt, by your ſcale, rule, and compaſſes, draw the line AB in length 3 chains 73 links, ending at the point B; then laying the center of your protractor upon the line AB, ſo as the center of it be upon the point A, and that end of the diameter from which the numbers are reckoned on the arch or limb towards B, make a point for the angle A at 89 degrees 10 minutes, by the direction whereof, and

the

the point A, draw the line A E, which according to your ſcale, muſt be 2 chains 29 links.

In like manner placing the diameter upon A E, juſt as it was upon A B, and the center upon the point E, mark out by the limb, for the angle E, 129 degrees 20 minutes, by which draw the line E D, 6 chains 64 links.

In the next place, bring the center of the protractor to the point D; its diameter lying on the line E D, and its limb towards A, by which prick out 67 degrees 15 minutes for the angle at D, and draw the line 1 chain 88 links.

Laſtly, The center being at C and the diameter upon the line D C, in ſuch manner as before at other angles, prick out by the limb or arch 137 degrees 30 minutes, and draw the line C B, for at B your plot ſhould cloſe; and if rightly done, the angle at B will be 116 degrees 30 minutes, and the ſide BC 4 chains 91 links, which you will find it to be by meaſure.

But if you plot by a line of chords, you are not bound to this order, but may go from A to B, and ſo round that way if you pleaſe, which you could not ſo well do with a protractor, without reckoning the numbers backward, yet it muſt be granted that a line of chords neither doth the work ſo quickly nor conveniently: this is the way.

When you have drawn the line A B of a proper length ſet the compaſſes to the radius, and placing one foot of the compaſſes in the point B, and with the other deſcribe an arch of a competent length, beginning at that ſide of the line A B that is deſigned not to be the inward ſide, and upon this arch, 116 degrees 30 minutes muſt be ſet; but becauſe the line of chords gives only 90, ſet them firſt on from the line A B, and then take off the remainder 26 degrees 30 minutes, joining them to the 90 upon the arch, making a point, through which the line B muſt be drawn of a due length. In the like manner you muſt do at C E, but the angles at A and D need no ſuch piecing, being capable of being meaſured out by a line of chords at once.

Nor do your angles only give you trouble in this kind of work, but your lines alſo will be often found too ſhort to receive the touch of an arch upon the radius, eſpecially if the line of chords be large, and your ſcale little; and ſo it may often fall out when you uſe the protractor upon ſuch ſhort lines as A E and C D of this laſt figure: in which caſe a rule muſt be applied to them, and they muſt be extended to a due length, that the arches may meet them without the figure. And if thoſe extenſions of lines, and deſcribing of arches, ſpoil the beauty of your plot, the matter is not great, it is ſo eaſy to be retrieved; for if you lay on a clean paper, and prick through every angle, lines drawn between thoſe points, will give you the plot neat and perfect.

The artiſt ſometimes loſeth his labour of protraction through ſome error in the field, ſo that his plot will not cloſe; it is therefore proper to know before you begin that work, whether it will or no; for which purpoſe if we take a number leſs by two than the number of angles in the plot, and thereby multiply 180, that product being found to be equal to all the angles, the plot will cloſe, this appears by our plot in the preſent work; the multiplier being 3, becauſe the angles are 5, and the multiplier muſt be two leſs than the number of angles.

	Deg.	Min.
180	89	10
3	116	30
	137	30
540	67	15
	129	35
	540	

This kind of trial is grounded upon two principles of Euclid and Ramus, mentioned in the beginning of this article, ſhewing that in all plain triangles, all the angles taken together are equal to two right angles, and that the ſides, conſequently the angle alſo, of every triangle figure, are more by two than the triangles of which it conſiſteth.

Concerning taking inacceſſible diſtances by the plain table, and acceſſible altitudes by the protractor.

Fig. 39. The ſubſtance of what is to be ſaid for the firſt of theſe, is gathered from the inſtructions given for plotting a field, by meaſuring only the ſtationary diſtance; but to make the caſe more plain to an ordinary capacity, ſuppoſe the line A C to be the unknown breadth of a river, over which a bridge of boats is to be laid, and the general, that he may inform himſelf what ſtore of boats and planks is neceſſary to be brought down, commands you to tell him the true diſtance from A, where he is at preſent, to C, a little boat-houſe on the other ſide the water.

To ſatisfy his demand, plant your table covered with a paper at A, cauſing one to ſet up a mark at B, at a good diſtance from you, along the bank of the river, the farther the better, if diſtance do not hinder ſight: then having choſen a point to repreſent A, and laid the fiducial edge upon it, direct your ſights towards C and B, and ſtrike lines towards them. Which done, ſet up a mark at A, and from thence meaſure to B, 6 chains 32 links, and ſo plant your inſtrument at B, laying the fiducial edge to the line A B, and turning about the head of the inſtrument upon the ſtaff, till through the ſights you ſee the mark at A, and then ſcrew it faſt.

In the laſt place take 6 chains 32 links off your ſcale, and ſet it on the line A B, from A to B, and laying the fiducial edge to the point B, from thence direct the ſights to C, and draw the line B C, meeting or cutting the line A C in C: ſo ſhall the ſpace A C meaſured on the ſcales, viz. 8 chains 29 links, be the diſtance deſired, and becauſe the chain is 22 yards long, if you multiply 8.29 by 22, the product is 182 yards and $\frac{38}{100}$ of a yard, which by reduction is ſome little more than 13 inches and $\frac{3}{5}$ of an inch.

Now, to take the height of a tree, tower, or ſteeple by a protractor, without any arithmetical operation, hang a plummet with a fine ſilk thread at the center of it, and hold it ſtedfaſtly with that end to your eye, where the numbers begin, then look ſtrait along the diameter, ſtill removing backward and forward as there is occaſion, till you ſee the top of the tree, tower, or ſteeple, and the thread at the ſame time fall upon 45 degrees, ſo ſhall the diſtance from your eye to the tree, tower, or ſteeple, meaſured in an horizontal or level line, together with the height of your eye above the bottom of it, be equal to the height of the object.

If either for convenience of ſight, or any other reaſon, you think proper to ſet the other end of the diameter to your eye, then the thread for the above trial muſt fall upon 135 deg. inſtead of 45.

Of caſting up the content of land by a table.

This table conſiſts of three columns, the firſt containing links, the ſecond roods, or quarters of acres, the third perches; and the uſe of it is thus:

Suppoſe a field to be 7 chains and 25 links long, and five chains 50 links broad, theſe by multiplication make 398750, whereof 5 figures being cut off towards the right hand, the figure 3 ſignifies acres, and the reſt, viz. 98750 denote parts; and to reduce them into roods and perches, firſt ſubſtract from 98750 the greateſt number of links in the table that can be ſubſtracted from it viz. 90000, and put down for it three roods 24 perches, which you find over againſt it in the annexed columns, and the remain being 8750, look in the table, and find over againſt it 14 perches, which by addition makes 3 roods 38 perches; ſo is the whole content of the field 3 acres, 3 roods, 38 perches.

7.25	
5.50	
36250	
3625	
3625	
3.98750	
A R P	
3 3 24	
14	
3 3 38	

But note here, that if the remainder after the firſt ſubſtraction cannot be found in the table, you may take the neareſt to it, ſo the error will be but part of a perch.

As for example.

7.75 being the half perpendicular, and 9.23 the baſe, give for their product 6.78405. The 6 ſignifies acres, and from the reſt 70000 being ſubducted, to which 2 roods 32 perches anſwer, there reſteth 8405; which, becauſe you cannot find in the table, you muſt take the neareſt, which is 8125, to which 13 perches anſwer; ſo the whole content of that triangular cloſe, is 6 acres, 3 roods, and 5 ſquare perches, and a little better.

6 3 05

SUSSINGLE, or *Surſingle*, the girt which comes over the ſaddle, and binds it firmly to the horſe.

SWAMP, a hollow, watery place, in any part of a field; a bog. *See* BOG.

SWANG, a freſh piece of green ſward lying in a bottom among arable or barren land.

SWARD, the ſurface of the ground.

SWARM, a large number of bees, ſeeking a proper ſettlement. *See the article* BEE.

SWATH, or *Swarth*, a line of graſs, &c. cut down by the mower.

SWATH-BAUK, a ſwarth, or line of new mown graſs or corn.

SWATH-RAKE, a rake about two yards long, with iron teeth, and a bearer in the middle, to which a man fixes himſelf with a belt, and when he has gathered as much as his rake will hold, he raiſes it and begins again. This inſtrument is in ſome counties called a dow-rake, and much uſed in Eſſex for gathering barley after mowing.

To SWEAL, to ſinge, or burn off the hair, &c.

SWILL, a veſſel to waſh in ſtanding on three feet.

SWINE. *See the article* HOG.

SWINE-CRUE, a hog's-ſty.

SWINE-HERD, a keeper of ſwine.

SWINHULL, a hog's-ſty.

SYCAMORE, the name of a tree well known in many parts of England. It grows to a large ſize; the wood is ſoft and very white, and therefore valued by the turners; but is not eſteemed very valuable for other purpoſes. However, as this tree will thrive better than moſt other ſorts near the ſea, it is frequently cultivated to ſcreen plantations of other ſorts of trees from the ſpray of the ſea.

SYTHE. *See* SCYTHE.

T.

TEA

TABERN, a cellar.

TAGGE, a ſheep of the firſt year.

TAIL-SOAKED, a diſeaſe incident to cows, by which the joint of the tail near the rump, will, as it were, rot away. The cure is generally performed by cutting a deep gaſh into the part affected, then rubbing a handful of ſalt into the wound, and binding it up with a rag. Others mix ſoot and a clove of garlick with the ſalt.

Wild TANSEY. *See the article* SILVER-WEED.

TARES. *See the article* VETCHES.

TEAM, a number of horſes or oxen drawning at once the ſame carriage.

To TEAM, to pour or lade out of one veſſel into another.

TEAZLE, or *Fuller's Thiſtle*, a ſpecies of the thiſtle cultivated for the uſe of clothiers, who dreſs their cloth with them.

The teazle is propagated by ſowing the ſeeds in March, upon a dry ſoil. About one peck of the ſeed will ſow an acre; for the plants ſhould have room to grow; otherwiſe the heads will not be ſo large, nor in ſo great quantity. When the plants are come up, you muſt hoe them in the ſame manner as is practiſed for turnips, cutting down all the weeds, and ſingling out the plants to about ſix or eight inches diſtance; and as the plants advance, and the weeds grow again, you muſt hoe them a ſecond time, cutting out the plants to a wider diſtance; for they ſhould be, at laſt, left at leaſt a foot aſunder; and you ſhould be particularly careful to clear them from weeds, eſpecially the firſt ſummer; for when the plants have ſpread ſo as to cover the ſurface of the ground, the weeds will not ſo readily grow between them. The ſecond year after ſowing, the plants will ſhoot up heads, which will be fit to cut about the beginning of Auguſt; at which time they ſhould be cut and tied up in bunches, ſetting them in the ſun, if the weather be fair; but if not, they muſt be ſet in rooms, to dry. The common produce is about an hundred and ſixty bundles, or ſtaves, upon an acre, and they will ſell for about one ſhilling a ſtave. *Millar's Gard. Dict.*

M. de Crateauvieux extended the New Huſbandry even to the culture of the teazle, or fuller's thiſtle, which grew to a ſurprizing height, and produced an extraordinary number of the fineſt and beſt heads that the fullers in his country had ever ſoon.

"I am well informed, ſays an ingenious correſpondent of the editors of the Muſeum Ruſticum, that the principal place in the kingdom for the cultivation of the teazle, is about Wrington in Somerſetſhire, many of the inhabitants of that, and the neighbouring pariſhes, being chiefly employed therein; and from theſe places the cloth manufactories in the counties of Glouceſter, Somerſet, and Wilts, are ſupplied, and even a great many packs carried annually into Yorkſhire.

"The land moſt ſuitable for this plant is that of a thin, ſweet ſurface, and marly bottom, though a clay or ſtone-traſh bottom will do, and produce large crops: rich loam, or ſtrong clay, is very improper, as on them the plant is apt to grow luxuriant, and thereby cauſe the heads to be large and coarſe-hooked, and, in a moiſt ſummer, ſubject to mildew and rot before they bloſſom and are fit to cut.

"As to ſituation, a ſouthern aſpect, on the decline of a hill, is to be preferred, though any other will do; but upland ground is to be moſt eſteemed, more eſpecially in an encloſed country, that the wind may aſſiſt in carrying off the natural humidity of the plant in moiſt ſeaſons, which ſometimes, in low and ſmall encloſures, is retained ſo long as to cauſe the heads to taint, and become rotten.

"Having made choice of a piece of ground, (an old lay is preferable) in February cauſe it to be ploughed in ridges of three bouts each, at a depth ſuitable for a crop of beans, taking care that the furrows be laid ſtrait, and as even as may be; the middle of the ridge higheſt, and a freſh furrow ploughed in the furrow between each ridge; after which let a man go along each ridge, and with a mattock, hoe, or ſpade, raiſe earth in ſmall clods, at ſuitable diſtances from each other, to produce earth, when meliorated, to heal or cover the ſeed.

"Having done thus much, let it remain as it is until the time for ſowing the ſeed, which will be about a week or ten days in April, as then the earth is generally moiſtened with rain.

"At this time cauſe a middle-ſized harrow to be drawn over the land once or twice in a place, to fill the crevices between each furrow, and level the ſurface; after which ſow the ſeed broad-caſt, in the proportion of two buſhels on an acre; then harrow it in, the ſame as turnip ſeed, and let it remain until the plants are come up, and grown into ſix or eight leaves each; when ſome perſon or perſons ſhould go over the field with a hoe, and cut out the plants, where they are too thick, to the ſize of about two feet from each other every way, if the ground be in heart; if it be thin poor land, ſixteen or eighteen inches diſtance is ſufficient.

"After

" After this they may remain until the latter end of Auguſt, when they muſt be gone over as before, with this difference, the perſon ſhould have a ſpade made about four inches broad, and eighteen inches long in the bit, or pan, with a tree in it of three feet ſix inches long: with this tool the workman muſt go backward, and turn the whole ſurface over, about two inches deep, in long ſpits, turning the ſpade from the plant, to turn the ſpit ſo as no earth may fall into the heart of the plant: but it would be adviſeable, at the time of firſt ſizing the plants, to leave more than are neceſſary to ſtock the ground, to have ſome to fill up the vacancies where any may happen to die, which is often the caſe during the ſucceeding winter, and more eſpecially ſhould it prove froſty.

" Having done thus much, in this ſtate they are to remain duing the winter; only care muſt be taken that no cattle get into the field, eſpecially ſheep, which will eat out the cabbage of the plant, and ſpoil it.

" About the latter end of the ſucceeding February, the plants ſhould be digged between as in Auguſt, being very careful that none of the earth falls into the middle of them; and in May, when the plants begin to ſhoot into ſpindle, the ground muſt be digged over again, with this difference, inſtead of being laid plain, it muſt be raiſed into ſmall hillocks about each plant, to ſtrengthen them in the ground, ſo that the wind may not blow them down when loaded with heads.

" This being done, they are left till the ſeaſon for cutting, which will be a work of ſome time, as the heads become fit, which is known by their blowing: it is to be obſerved that the bloſſom firſt appears near the bottom of the head in ſmall, pale, blue flowers; and when theſe appear to have blown ſomewhat more than half way up, ſuch head is fit for cutting, which is generally done in this manner; a man has a knife, the blade about two inches long, with a ſtring in the haſt to put over the hand, and a pair of ſtrong gloves to defend him againſt the ſharp prickles on the ſtalks.

" Being thus equipped, he muſt go along each furrow, and cut with one hand, putting them into the other, till he has as many as he can eaſily gripe; when cutting one which is a little more ripe than the others, and the ſtem about eighteen inches long, he binds the handful together with it, (the others are generally cut about nine inches long) which done, the handful is toſſed to ſome open ſpot, in order to be carried to the place for drying, which is done in the following manner.

" Some ſmall poles of aſh, willow, or any ſtrait-growing wood, about the ſize of a hedge-ſtake, and ten or twelve feet long, muſt be procured, at the great end of which, about eighteen inches from it, a hole muſt be made, and a peg put through, to extend three or four inches on each ſide. The poles thus prepared, the handfuls of teazels muſt be put on them, by running the ſmall end through the handful, until the pole be filled: in this condition they muſt be ſet on one end to dry; but it is to be obſerved, that they ſhould be careſully carried into a houſe or ſhed every night, and brought out at days; and in the houſe ſet ſo as for the poles not to touch each other, leſt they taint, which for want of a free circulation of air, they are very ſubject to, and more ſo, if it be cloſe moiſt weather.

" When they are dry, ſo as to be free from moiſture, they may be carried into ſome upper room, and placed up cloſe together: over a cow-houſe, or place where cattle are fed in winter, is to be preferred, becauſe their breath is ſuppoſed to help to brighten them in colour; wherefore they are the better eſteemed, and ſuppoſed to be more tough in hook than otherways they would.

" When they have by this means acquired from the gradual moiſture of the air an additional elaſticity to the hooks, and are brightened in colour, which will be completed a little after Chriſtmas; the time that generally the heads are ſorted, and made out in the following manner. The handfuls are brought from the ſtorehouſe into ſome large room, uſually a barn-floor, where they are untied, one at a time; and generally made four ſorts of. The largeſt heads which are ſound, and are ſuch as grow on the middle ſtem of each branch, are thrown for the firſt ſort, and called kings. The next ſmalleſt which are ſound, and are commonly ſuch as grow as ſide heads on each branch, are thrown for a ſecond ſort, and are called middlings. Another, or third ſort, are ſuch of the largeſt, or thoſe which grew on the middle ſtem, as are damaged by the mildew, wet, or other accident; and which would have been kings, had not ſuch defect rendered them unworthy that appellation. The therefore are thrown to a third ſort, and denominated ſcrubs. Theſe laſt, or fourth ſort, is the refuſe of all, and are ſuch as are too ſmall, or too much damaged for any uſe; and are therefore thrown away.

" When a quantity is thus ſeparated, they are made out in the following manner: the perſons who do it, put of the kings ten in each handful. Firſt, ſix of the larger, in the manner of a fan extended: and four leſſer of the ſame ſort, in the boſoms of the ſix; and then bind their ſtems together with a ſpleet of willow, or ſome tough wood, by wrapping it about them three or four times, and tucking the end under. When the kings are tied up in handfuls in this manner, a ſtrait ſtick of about three-fourths of an inch diameter, and two feet ſix inches long, is ſplit to within four inches of one end. Twenty-five of theſe handfuls are put on this ſtick, alternately head to ſtem; letting two of the middle ſtems of each handful to be in the cleft, to hold them ſecure; then a ſmall wreath, made of ſpleet, is ſlipped on the upper end of the ſtaff, which holds it together, and keeps the whole from falling about. In like manner are the ſcrubs, or third ſort, alſo made out and put in ſtaves. But of the middlings, or ſecond ſort, double the number of heads are put in one handful, by making two fan-like rows of ſix each, and four in their boſoms on each ſide; and theſe are put into ſtaves of three feet long each, ſplit as the former, and thirty handfuls in each ſtaff. When they are thus made out, they are fit for ſale, and are to be laid by for that purpoſe in ſome convenient place, where they may not be bruiſed. Thirty ſtaves of the firſt and third ſort are accounted a pack; and forty ſtaves of middlings make alſo a pack.

" An acre of land, if well grown, and what is deemed a full crop, often produces nine packs of kings, nineteen of middlings, and two of ſcrubs. The common price per pack of the firſt ſort, is twenty, the ſecond ſort fourteen, and the third ſort eight ſhillings. But in a French war, they are generally double theſe prices.

The expence attending a crop per acre are,

	l.	s.	d.

All which make the total expence, attending one more acre of teaſels	13	5	0

" This, excluſive of ſeed, which is not often bought, becauſe enough may be ſaved in making out the crop in winter: but if the ſeed be bought, it is generally valued equally with wheat. Therefore, if two buſhels be ſown on the acre, ten ſhillings may be added as the medium price; which makes the whole expence of one acre thirteen pounds fifteen ſhillings, if it ſhould produce thirty packs. But ſuch produce is not always the caſe, for twenty is to be eſteemed a middling crop.

" With reſpect to crops of corn, raiſed amongſt the plants, it is practiſed in many places; and indeed it has been mine to plant field beans, or garden beans, at about three feet diſtance ſingly from each other, in a promiſcuous manner over the teaſel land: which crop of beans, by the cultivation neceſſary for the teaſel, is greatly forwarded in growth, and often produces from four to five and ſix ſtalks from one bean, well loaded with cods. This crop is no injury to the teaſel crop the firſt year, and frequently pays the expence of labour attending the whole.

" The crop, which generally ſucceeds the teaſel, is wheat. The ground, by being frequently delved and kept clean, during the teaſel crop, becomes very fit for this grain, and generally produces very large crops. Forty buſhels per acre is not uncommon, though the land in itſelf is often ſuch as is not annually worth more than ten ſhillings per acre. Hence, I think, it is evident, that a crop which well ſhades the ground, (in ſummer) and that has been two or three times turned and cleaned from all weeds, before ſuch ſhading, greatly fertilizes the land on which it grows. But I have frequently obſerved an error, to which the occupiers of ſuch land are too liable after theſe fertiliſing crops. This error is the ploughing away (by over-cropping) the profits which would enſue. If after its being thus fertilized by the crops of teaſels, it were to be laid down with ſuitable artificial graſs-ſeed, ſown amongſt wheat and properly managed afterwards, it would, I am experimentally ſenſible, be a laſting improvement." *Muſeum Ruſticum, vol.* III. *p.* 237, *and vol.* VI. *pag.* 1.

To TED, to ſpread abroad new mown graſs, which is the firſt thing done in order to its being dried, and made into hay.

TEDDER, *or* TETHER, a rope with which a horſe is tied in the field, that he may not paſture too wide.

To TEEM, to be pregnant; to engender young.

TENDRIL, the claſper of a vine, or other climbing plant.

TENEMENT, any thing, as a houſe, &c. held by a tenant.

TENURE, the manner in which tenants hold their lands, &c. of their lord.

THATCH, ſtraw laid on the top of a building, rick, &c. to keep out the weather.

THEAVE, or THIEF, an ewe of the firſt year.

THETCHES. *See the article* VETCHES.

THICKET, a cloſe knot, or tuft of trees; a cloſe wood.

THILL-HORSE, or THILLER, the laſt horſe in a team; the horſe that goes between the thills or ſhafts.

THISTLE, a well known prickly weed growing in corn-fields.

Where-ever thiſtles grow naturally, it it a ſure ſign that the land is ſtrong: but they are, at the ſame time, a great annoyance to every plant intended to be cultivated. The beſt way to deſtroy thiſtles is to cut them up by the roots before their ſeeding time, which is in the autumn; for cutting of them too young, will only make them branch the more: or, which Mr. Liſle prefers, to pluck the thiſtles up by hand, when the ground is reaſonably moiſt before they are grown to the ſize at which they are uſually cut. They may then be eaſily drawn up with their root by the thumb and two fingers; and the weeder may guard againſt their prickles by putting on a glove, or falſe fingers, made of hard leather. Chalking of land is a good way to deſtroy this very noxious growth: but thorough tillage, ſummer fallows, and repeated good harrowings, are the moſt effectual of all.

By an excellent regulation in France, a farmer may ſue his neighbour who neglects to thiſtle his land at the proper ſeaſons, or may employ people to do it at the other's expence. And it were to be wiſhed, that a ſimilar law was enacted here, to prevent the wide-ſpreading miſchiefs occaſioned by the ſeeding of this pernicious weed; among which may be reckoned, beſides its choaking the young corn, that if wheat, in particular, be not well thiſtled, the reapers take up the grips ſo tenderly, leſt they ſhould prick themſelves, that, by their looſe handling of them, they ſometimes leave upon the ground corn enough to ſow the whole field.

THISTLING, the action of cutting or pulling up thiſtles, in order to deſtroy them.

THRESHING, the action of beating out the corn.

Though the flail be the beſt inſtrument yet known for threſhing the corn, becauſe it ſeparates the grain from the ſtraw and huſks very effectually and expeditiouſly; yet, as it always bruiſes a great many ſeeds, even ſo as to render them incapable of growing, it were much to be wiſhed that ſome method could be found, by which this eſſential inconvenience might be avoided. Some engine or other provided with a number of flails, or other pieces anſwering the ſame end, might ſurely be made to move by water, wind, or a horſe, ſo as to perform the buſineſs of threſhing ſtill cheaper and more expeditiouſly, and with leſs damage to the health of the huſbandman, which is frequently thought to be injured by the duſt, &c. which ariſes in the common way of threſhing, as well as by the very great laborioufneſs of the work. This well deſerves the attention and endeavours of ſkilful mechanics. At all events, the threſher ought not to wear thick iron-clouted ſhoes whilſt he is at work, eſpecially if he is to threſh new corn, and particularly wheat; becauſe they will be apt to bruiſe it. His ſhoes for this purpoſe ſhould be ſoled with an old hat, or ſome other ſoft ſubſtance.

Mr. Mortimer eſteems it a day's labour for a man to threſh four buſhels of wheat or rye, ſix buſhels of barley, five buſhels of oats, or five buſhels of beans and peas, if the corn threſh well. But Mr. Liſle ſays a good threſher aſſured him that twelve buſhels of oats or barley are reckon-

ed a good day's threſhing: that this very man had threſhed fourteen buſhels of oats daily, and winnowed them, for ſeveral days together; but that thoſe oats yielded indeed extraordinary well: that five or ſix buſhels of wheat are a very good day's threſhing; and if the corn be clung, and yields ill, ſometimes three buſhels are as much as can be threſhed in a day. He rates the common price of threſhing at eight-pence for a quarter of corn; and obſerves, which may account for the difference between his eſtimate and Mr. Mortimer's, that ſix buſhels of wheat of the growth of a warm gravelly vale are as eaſily threſhed in a day, as four buſhels of the produce of cold hilly land; becauſe the ſtroke of the flail muſt be forced down ſtronger to beat out the grain of this laſt, than it need to be for the former: and alſo, that as the ſtraw of corn of the growth of a light ſoil is ſhorter than that of a ſtrong clayey ground, more ſheaves, and conſequently more ears of this firſt ſort, may be laid together on a floor of equal extent, than can be of the laſt, whoſe longer ſtraw requires proportionably more room.

The worſe wheat is, though it be never ſo dry, the rougher it will feel when handled; becauſe thin and coarſe wheat is not ſo plump and globular as fine wheat, but is apt to be pitted and wrinkled, which of courſe renders it leſs ſlippery. It will handle cooler out of a ſtack two years old, than it will out of one that is only a year old; for in that time the miſts and rimes, eſpecially in a hilly country, will be driven into the ſtack.

Mr. Liſle, who makes this remark, adds from his own experience, that wheat threſhed in damp weather generally yields but little flour, with a great deal of bran, when it is ground; and that if it be put into ſacks, it will grow muſty in leſs than three weeks, let the weather be ever ſo dry afterwards: but if it be threſhed when the air is perfectly clear and dry, it will keep well in ſacks, for a long time; eſpecially if theſe are laid upon treſtles high enough to ſecure them from the dampneſs of the ground or floor.

For the keeping of meal, in general, there is no better way than firſt to bolt it, and clear it from the bran, which is very apt to corrode and putrify it, and make it muſty; then to tread it down as hard as poſſible, and head it up cloſely, in clean, dry, tight, and well bound caſks, which muſt be laid in a cool dry place.

The beards of barley come off beſt, in threſhing, when the ſwarths of this corn have taken the dew before their being houſed. It will keep well in the mow, unthreſhed, for one year; and for making it into malt, which muſt be done before the heat of the ſummer comes on, it ſhould not be kept above a year and a half, or at moſt two years: otherwiſe it will be filled with weevils; unleſs it has been previouſly cured in a ſtove or kiln.

Oats, being defended with a double huſk, are the grain leaſt ſubject to harbour vermin. The beſt way to keep them after they are threſhed, is to dry them well on a kiln, and then to barrel them up in clean cloſe caſks: but they ſhould not be threſhed earlier than Chriſtmas, becauſe they are not fit for keeping before that time.

Beans and peas always threſh beſt after they have ſweated in the mow, which they are very apt to do, becauſe, as the whole crop of either of them never ripens all together, the green parts heat, and communicate their ferment to the whole heap. The danger to be guarded againſt here is, that the ripe ſo heated do not give fire to the green, by which both might be either rotted or conſumed; to which the bigneſs of their leaves, and hardneſs of their ſtalks, which, continue moiſt and ſappy a long time, will alſo contribute very much. For this reaſon farmers generally chooſe to ſtack them without doors, rather than to houſe them; that they may be the more thoroughly dried by the ſun and air. But the beſt way of all is to kiln-dry them, or dry them well in the ſun; after which they will keep many years, without turning or any other care, though they be laid ever ſo thick in the granary. As beans are a very large ſeed, and conſequently full of moiſture, it is found beſt to let thoſe that are intended for keeping ſweat in the mow till March, when they may be threſhed without danger: for beans never give again, after they have once been thoroughly dried.

Peas are, of all grain, the moſt ſubject to rottenneſs and imperfection, becauſe they are the moſt apt to breed worms, weevils, and mites, by reaſon of the luſciouſneſs and ſweetneſs of their grain. The better they are dried either in the kiln or ſun, the former of which will generally be found moſt effectual in this country, the longer they will keep ſound, and the fitter they will be for the food of cattle, by helping to make them thirſty; it being a juſt obſervation, that if cattle drink well, they will feed well. What is intended for the food of men ſhould not be dried too much; becauſe that would make the peas require double the time in boiling: nor need they be threſhed for this uſe, but as they are wanted; or elſe they may be put into cloſe caſks, and headed up. In granaries, they keep beſt in thick heaps, or in bins; ſpreading of them thin upon the floor being apt to dry them too ſoon, and to take from them much of their ſweetneſs and goodneſs.

Vetches wanted for ſowing immediately after they are cut, may be threſhed very well on a hurdle, with a cloth; though they may then be too ſoft, notwithſtanding their being ripe, to be threſhed on a floor, where the flail, and the threſher's feet, would bruiſe and break them.

When a careful huſbandman opens and ſpreads his ſheaves, he will pick out of them at leaſt all the largeſt and moſt apparent weeds, before he begins to threſh. As he proceeds in his work, he will, from time to time, remove all the long ſtraw from the corn beaten out of it, which laſt always lies underneath, with a prong or fork; and then the pieces of ſtraw, broken ears, &c. with a wooden rake. He will then ſhovel the remaining grain up on one ſide of the floor, and repeat this till he has threſhed out enough to make what is commonly called a clearing.

This heap is then paſſed through a wide ſieve, which retains only the bits of ſtraw, and ſuch fragments or ends of the ears as have eſcaped the flail. Theſe frequently contain very good corn; though the farmer ſeldom grudges giving them to his poultry, or binding them up with ſtraw intended for fodder. A few of them incloſed in a ſmall truſs bound at both ends, the better to keep them in, will entice horſes to eat heartily of this ſtraw, which affords them good nouriſhment: and M. Duhamel judges that they would alſo be excellent and profitable winter-food for ſheep, when there is a ſcarcity of graſs.

A great deal of labour may be ſaved in the uſing of this ſieve, by faſtening a loop to its rim, and reſting it thereby on a hook ſuſpended by a rope. This will ſuſtain half the weight of the corn, and the winnower may eaſily give it the neceſſary circular motion. But a yet more convenient method, is to place a ſquare ſieve, of wire is beſt, with thin boards for its ſides, upon two poliſhed rods of iron, to throw the corn up into it with a ſhovel, and to

puſh

puſh it backward and forward upon theſe rods, on which it moves eaſily, and will ſift a great deal of corn in a ſhort time.

For ſeparating the chaff, which is the next buſineſs, the caſting-ſhovel is much more expeditious than either the wicker fan, or the common winnow with ſails. When this ſhovel is uſed, the wind muſt blow through the barn, either in at one door and out at the other, or in at a window, and out at the oppoſite door. The winnower then, placing himſelf under the wind, and cloſe to the heap of corn that is to be cleanſed, takes it up, one ſhovelful after another, and, with a circular motion, throws it ſcattered in the air, againſt the wind, towards the oppoſite ſide of the barn. The beſt grains, which are the heavieſt, go fartheſt; the leſſer fall ſhort of them; and the very ſmall, ſhrivelled, and much damaged, with the ſeeds of cockle, darnel, and ſeveral other weeds, fall ſtill nearer to the man who throws them; while the lighter ſeeds of other weeds, with the bits of ſtraw, chaff, duſt, &c. are blown from all the reſt, by the wind. From time to time, the winnower quits his ſhovel, and ſweeps away the ſecond ſized corn, which would be too much intermixed with the ſmalleſt, if the heap was left alone, and ſuffered to accumulate till the end of the winnowing; and when the whole is done, he ſhovels up the fineſt grain. The leaſt of all, which borders on the chaff, &c. is alſo then collected, and the three ſorts, after being ſifted or ſcreened, to cleanſe them from any remaining duſt, are laid up ſeparately; the firſt for ſale, the next for domeſtic uſes, and the third, if the farmer can afford it, chiefly for the food of poultry. The ſhort ſtraws and chaff are ſifted in a pretty fine ſieve, to clear them likewiſe of duſt, and are frequently given to oxen and cows.

Mr. Liſle obſerves that the ſeeds cannot be ſeparated from any grain by the common fan, but that it may be done with the ſcreen; of which he therefore adviſes the conſtant uſe for all ſorts of corn deſigned for ſowing.

Though wind is, in all caſes, the chief agent in the cleanſing of ſeeds, which being intrinſically heavier than their coats or huſks, are, by the ſame force applied to both, carried to different diſtances, in proportion to their weight, and thereby conſequently ſeparated; yet the natural action of this aſſiſtant is liable to many inconveniencies: it blows not conſtantly; but frequently diſappoints the winnower in his time of greateſt need: when it does blow, it is not always in the beſt direction to anſwer the ſituation of his barn; and without doors it is intirely uſeleſs to his purpoſe, if it be not attended with fair weather. Beſides, when its force can be applied in the beſt way, it is even then not equal; but generally acts by ſudden blaſts, which, as is well known, diſorders the whole work, and occaſions a conſiderable waſte of ſeed.

The Dutch avoid theſe inconveniencies by uſing a machine (Plate XXVI. Fig. 1.) which creates an artificial wind, uniform and ſteady in its action, and always ready at command.

The fan, (Fig. 2.) which is the acting part of this engine, produces a wind proportioned to the velocity with which it is turned on its axis, and therefore capable of ſeveral degrees of ſtrength, as beſt ſuits the purpoſe of the winnower.

This fan is incloſed in a large caſe or box, K L, and occupies one half of it; which is repreſented ſeparately, and in a different view, in Fig. 3. It is ſuſpended freely on its axis, and turned by the handle A. The other half of the box is empty, and receives the ſeed as it falls down from the hopper B, to the ſloping floor viſible at C, along which it ſlides out at D, while the force of the wind which is confined within this winnow, and always acts in the ſame direction, viz. lengthways of the machine from A to E, carries the chaff, light and rotten grains, dirt, &c. out at E. In this paſſage, the wind meets the ſeed conſtantly falling from the hopper, and impels it more or leſs towards the end E, according to its weight. Good ſeed never goes quite ſo far, but comes down within the box.

The hopper here is ingeniouſly contrived to ſave labour. It hangs by ſtrings upon four pegs, and moves with ſuch eaſe, that the neceſſary motion may be communicated to it by the ſame hand that moves the fan, without any hindrance to the workman. To this purpoſe, a triangular board *f*, is fixed upon the handle of the fan, and turns with it. The angles of this board, in their rotation, preſs againſt the lower end of a little lath, incurvated as in the figure, which moves freely upon a peg at *g*. This end accordingly recedes from the preſſure towards H, and conſequently the upper end moves the contrary way, towards I, and by a ſtring faſtened from it to the hopper, draws this laſt after it, out of its natural ſituation. When this preſſure ends, and the ſides of the little triangle are next to the lath, the hopper hangs freely, returns to its former place, and takes the lath along with it, till the next angle of the little triangle begins to act; and ſo alternately as long as the fan moves. As the hopper is thus in continual motion, the ſeed ſheds down, and is winnowed as it falls.

The next care is to cleanſe the corn from all foreign bodies, which could not be carried off by the wind, ſuch as ſtones, bits of earth, &c. Theſe are ſeparated by running the grain through a ſieve wide enough to let it paſs with eaſe, while bodies of a larger bulk are retained: and it is likewiſe often neceſſary afterwards to uſe a fine ſieve, which lets through only the duſt, ſeeds of weeds, and other bodies ſmaller than the corn.

As the farmers in many places feed their cattle, and particularly their ſheep, in the winter, with half-threſhed ſtraw; and as new ſtraw is good food for horſes, which are induced to eat it very readily when it ſtill contains ſome grain; there is, in this reſpect, an advantage in threſhing the corn only by degrees; beſides, that the grain itſelf is allowed to improve in its quality when preſerved in the ear, ſo as to attain the moſt perfect maturity, to ſweat out its moiſture, and to acquire a degree of hardneſs which fits it for long keeping. About three months after it has been cut, is generally reckoned the beſt time for threſhing wheat that is intended for keeping; and accordingly our prudent huſbandmen make this the buſineſs of winter, when their preſence is leaſt wanted in the field. But, on the other hand, ſeed wheat cannot well be too ſoon cleared from the chaff, as M. de Chateauvieux's experiments have proved; and the beſt way of doing this, is by ſtriking the ears againſt a beam. By this method the huſbandman will obtain fine, long, unbruiſed ſtraw, fit for binding up his next year's ſheaves, for thatching, and for various other uſeful purpoſes. Of this he ſhould always ſave, and ſtack, as much as he can ſpare, when it proves long and good; for wheat ſtraw will keep perfectly well a year or two: and if there be no occaſion for it in that time, it will make litter and dung at laſt. Barley ſtraw is likewiſe very ſerviceable for thatching, or to throw over ſtacks of barley, or peas, till they can be thatched: but oat ſtraw is of no great uſe

unleſs it be to cover an oat-rick, peas for fatting hogs, or corn for fowls. In general, an empty ſpace ſhould be left in the barn, if it can be done conveniently in harveſt time, to receive the litter, and foddering ſtraw, that is threſhed out before cattle come to fodder; or it ſhould be laid under ſome cover, for otherwiſe it will rot.

THRASHING-FLOOR, the floor on which the corn is thraſhed. *See the article* BARN.

THRAVE, a ſhock of corn conſiſting of twenty-four ſheaves.

THREAF, a handful, a bundle, a pottle.

THROATING, the action of mowing beans againſt their bending, which is never done but in a thin crop.

THROATWORT, the name of a perennial weed common in paſture grounds. The ſtalk is cornered and undivided. The flowers grow in bunches at the top of the ſtalk. They are erect, of a beautiful purple colour, and divided in the middle into five acute ſegments.

TICHING, ſetting up turfs in ſuch a manner as they may be dried by the ſun, and fit for being burnt for their aſhes upon the land.

TIKE, an inſect found in dogs, ſheep, cows, &c.

TILLABLE, arable, fit for the plough.

TILLAGE, the act or practice of tilling, or cultivating land. *See the article* PLOUGHING.

"I was much pleaſed, ſays a correſpondent of the editors of the Muſeum Ruſticum, with an account which I received about ſix weeks ago, of a peculiar management of tillage at Market-Weighton, in the eaſt-riding of Yorkſhire, given to me by a ſenſible man of veracity, who was born and bred a farmer in that neighbourhood.

"The inhabitants of Market-Weighton have it ſeems five fields, two of a ſandy ſoil, and three of a ſtrong clayey ſoil; the former, as will eaſily be conjectured, deſtined to rye, and the others to wheat. Their ſandy lands are diſpoſed to four ſwathes breadth; and finding by experience that conſiderable parts of each land, towards each furrow, are ſtarved by the coldneſs of the water dripping from the higher parts of the lands, they have for many years altered their former method: and only ploughed the half of each land, viz. the two middle ſwathes: ſo that they have now excellent rye growing on the higher and dryer half of every land, and excellent meadow growing on the lower and wetter half, which being juſt two ſwathes, is mowed with great eaſe and exactneſs.

"It will, perhaps, be thought by ſome, that by making narrower lands, they might have more dry land, and conſequently more corn. But I apprehend, theſe induſtrious huſbandmen find by experience, that when they make their lands narrower, and conſequently with leſs deſcent, the water ſtagnates in the higher parts, and conſequently ſpoils their whole crop. Nor could they, I ſuppoſe, ſow more corn on their lands, in their preſent diſpoſition, with convenience, as their preſent method allows them juſt one ſwathe on each ſide.

"They have rye and meadow in one of their two ſandy fields every other year, and a fallow the next year. The having half of the field in graſs, affords good graſs for their ſheep, &c. in that year; and allows them to keep a good ſtock thereon; and this ſtock, in return, manures the ground conſiderably, both the fallow and the ſwarth. One of their wheat-fields affords them plenty of worſe or ſpring corn; and thus they are ſupplied with wheat, rye, ſpring corn, meadow, and ſummer graſs, from their five fields, which in any other management they could ſcarcely be.

"It is obſervable alſo, that by this management they only plough as much as four fields, and conſequently can afford one fifth more ploughing to every piece of ground in tillage, than they otherwiſe could, on ſuppoſition that their fields are all of the ſame extent.

"Theſe provident people, gentlemen, have another piece of management well worthy the attention of others. They have two great fairs for ſheep; one in ſpring, and the other in autumn. They hold the former of theſe fairs in one of their fallow fields, which is to be ploughed up in ſpring. The concourſe of ſheep, horſes, &c. manures this field ſurpriſingly, and then they turn in the dung before it be evaporated or baked. Their later fair is held on the other fallow field, which is ſoon to be ſown with hard corn. And here they receive equal benefit.

"Whether they have their ſpring fair on the rye or wheat field, I know not; but I apprehend them to have it on the former, as rye is ſown ſooner than wheat; and the time of ſowing might be too late for their autumnal fair.

"Whoever has ſeen the uſeleſs naſtineſs which is made by ſheep at fairs, in the ſtreets of great towns, will think this management of the Market-Weightoners highly deſerving of imitation; eſpecially in the latter end of the year, when the rains bring in much ſoil with the ſheep.

"I would, however, venture to recommend one improvement to theſe ſenſible people, viz. after a certain number of years to plough up one of their ſandy fields intirely, and to croſs-plough it, and endeavour to mix the ſoil of the ridges and furrows thoroughly together, and then to make the furrows where the ridges were, &c. and to ſow down the outward ſwathes of each land with ſeeds proper to the ſoil. The advantages hence reſulting, are ſo obvious, that it would be an affront to their underſtandings to inſiſt upon them." *Muſeum Ruſticum, vol.* VI. *pag.* 83.

TILLER, a branch or ſtem of corn.

To TILLER, to ſpread or ſhoot out.

TILLS, tares, or vetches.

TILTH, *or* TILT, the condition of the earth after ploughing, &c.

TIMOTHY-GRASS, the name of a graſs now cultivated in England, of which it is a native, though the ſeeds of it were carried from Virginia, by one Mr. Timothy Hanſon, to North Carolina, where it is now cultivated by the inhabitants; and from this circumſtance it received the name it now bears.

It thrives moſt in low, damp, marſhy gounds; for in ſuch ſoil and ſituation it will produce a fine turf in three weeks from the time of ſowing the ſeed. It is very luxuriant, grows to a conſiderable height, and has in ſome ſort the appearance of wheat or rye, having a broad blade or leaf.

All ſorts of cattle are very fond of this herb whilſt in a green growing ſtate; and it will not be improper to add, that they are nearly, if not quite, as fond of it, when dried and made into hay: but when it is intended for this uſe, it ſhould always be mown when it is in full ſap, juſt before it flowers, for if it is left longer before it is cut, being ſo luxuriant and quick a grower, it becomes harſh, and is much dryer and more chirky food, than when it is cut in its prime.

"Timothy

"Timothy-graſs, ſays an experienced farmer, in a letter to Dr. Templeman, is in appearance a coarſe graſs, very little promiſing to be a paſture agreeable to cattle. Indeed, its appearance ſo ſtrongly prejudiced many againſt it, that it would have been at once condemned to neglect, had it not been reſcued by the enterprizing diſpoſition of Mr. Rocque, who had ſown a conſiderable ſpot of ground with the ſeed firſt ſent from America; yet the fact is, that, whilſt in the ſap, it is more agreeable to horſes and cattle than any other graſs has been obſerved to be. Mr. Rocque's horſe ſoon gave him a convincing proof of this; for having got looſe, he left very fine lucern, and the moment he reached the Timothy-graſs, inſtead of ranging about, as uſual with horſes, he eat clean before him.

"Deer, which are very nice in their food, are ſo fond of it, that, as I am well aſſured by gentlemen from North-America, they ſow Timothy-graſs there on the ſkirts of their corn land near the woods; in order to keep the deer from eating their corn; the Timothy-graſs being much more agreeable to them than even corn.

"The dry hay of the Timothy-graſs is exceedingly agreeable to cattle, as appears from a remarkable inſtance mentioned in a converſation in the Society for the encouragement of arts, &c. A worthy huſbandman, who had himſelf often experienced how fond his cows and horſes were of it, carried a friend into the field, that he might have ocular demonſtration of it. The huſbandman took a tuft of dry Timothy-hay in his hand, and as ſoon as one of the cows ſaw it, ſhe came inſtantly to feed on it, though there was plenty of good graſs under foot. Another cow ſoon followed the firſt, and both eat greedily of it: but each of them refuſed to eat the hay of common graſs, which happened to be mixed with it. So fond were the horſes and cows of this hay, that they would follow a perſon having ſome of it in his hand, as readily as they would one who carried corn for them.

"A very great advantage attending the Timothy-graſs is, that it thrives well in ſuch wet marſhy land as will ſcarcely yield any other good graſs; and here, its numerous and matted roots make ſo ſtrong a ſward, that land which was before a looſe mire, ſhall become ſo firm as to bear cattle and even carriages without their ſinking into it.

"It is almoſt needleſs to add, that in order to ſow Timothy-graſs ſeed in ſuch marſhy land, it muſt be drained, and then all the inequalities common in ſuch land, as well as the ſtrong matted roots of coarſe graſs, ſhould be taken up and burnt. The land being then ploughed and laid ſmooth, the aſhes ſhould be ſpread upon it, and the ſeed may be ſown early in the autumn; or rather, the plants ſhould be raiſed in a nurſery, and ſet in it at ſix or eight inches diſtance, every way, from each other. This graſs will alſo thrive well on a clay bottom, where water is apt to ſtagnate in rainy ſeaſons.

"The Timothy-graſs will grow to the height of three or four feet. I have been aſſured by a gentleman, that he has ſeen it between five and ſix feet high in Virginia. If it is cut down before the ſeed ripens, it will ſoon ſhoot anew, and yield a good ſecond crop. The ſowl meadow graſs grows to the height of about three feet, and will ripen its ſeed twice in a ſeaſon: we may therefore infer, that it may be cut for hay thrice in a ſeaſon. It is not an early graſs; but as ſoon as it begins to ſhoot, it makes up for that loſs by its ſpeedy growth. During the drought of laſt ſummer, the ſecond crop made a ſurprizingly quick progreſs. Its not being an early graſs is perhaps no loſs; for as it delights in rather moiſt meadows, the ground might be poached, were cattle tempted to go early to feed on it.

"If from ſome imperfection in the ſoil, the plants of either of theſe graſſes do not fill the ground ſufficiently, they may be let to run to ſeed, which falling in the vacant ſpaces, ſoon ſupply the want. So far as we have yet obſerved in this country, theſe ſelf-ſown plants do not arrive at the ſize of the parent plants, which were ſet at due diſtances: and this affords good reaſon to think, that if the ſeed was ſown in broaſt-caſt, and the plants came up thick, they would in the ſame manner be ſtinted in their growth.

"The ſucceſs of the Timothy-graſs, when ſown alone, demonſtrates the utility of ſowing the ſeeds of each graſs ſeparately, in order to form a juſt eſtimate of their comparative values: for though this graſs is a native of England, being a ſpecies of the fox-tail, it has hitherto been rather neglected than cultivated, even though nature has pointed it out as an uſeful plant in wet meadows, by its early verdure and growth. I make no doubt but that the practice of raiſing graſſes ſeparately, will bring other no leſs valuable graſſes to light."

TINE, a tooth or ſpike. And hence the common phraſe, of giving two or three tinings, ſignifies to draw the harrows twice or thrice over the ſame ſpot of ground.

TIT, a ſmall horſe.

TORE, rowen, or winter-graſs.

TOVET, or *Toſet*, half a buſhel.

TRAMEL, an inſtrument or device, made ſometimes of leather, but more uſually of ropes, fitted to a horſe's legs to regulate his motion, and teach him to amble.

Tramel alſo ſignifies an iron inſtrument hanging in the chimneys, whereon to hang pots or kettles over the fire.

TRANSPLANTING, the act of removing trees or plants from the places where they are ſowed, or raiſed, and planting them in others. *See the article* LUCERNE, PLANTING, &c.

TREE, the firſt and largeſt of the vegetable kind, conſiſting of a ſingle trunk, out of which ſpring forth branches and leaves.

Plantations of uſeful trees might be made to very great advantage in many places in every country, and the country greatly enriched by it, while the public would be alſo benefited by it, ſince it would raiſe a continual ſupply of timber uſed in ſhip-building, and on other public as well as private occaſions.

We have, in many places, heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public, to bring theſe to be truly valuable? Many, if not all of theſe heaths, would be found on trial capable of producing trees; and ſome of them are truly the remains of deſtroyed foreſts; and, though the profits to be reaped from the planting theſe would come late, yet the expence of doing it would be very trifling in compariſon of that profit, and the means eaſy.

The authors who have given rules for planting, having employed themſelves only about ſmall ſpots of ground, the eſtabliſhing orchards, or parks, are by no means to be ſuppoſed proper guides in attempts of this kind; and Monſieur de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who ſeem to ſpeak of every thing from their own experience, found, when he ſet about large plantations, that their opinions and rules

were erroneous; and was obliged to have recourſe to experiments only; which he varied a thouſand ways: and, though many of them proved unſucceſsful, yet they all gave hints towards others, by which the attempt might afterwards be brought to ſucceed.

This ſagacious enquirer into the operations of nature in the growth of vegetables, having ſet apart a conſiderable quantity of land for the trial, and procured a number of young trees, firſt divided the whole quantity into a number of ſmall ſquares, and, having made a plan of it, examined the nature, depth, and other circumſtances of the ſoil in each, and minuted the whole down on a proper part of the plan; that himſelf or whoever ſucceeded him might judge, from the different growths of a number of trees planted in the ſame ſtate in the different ſoils, the different advantages and diſadvantages of every circumſtance in the depth and nature of the ground, in regard to the growth of uſeful trees. Different numbers of labourers were employed about different ſpots of this ground, and the acorns for the young growth planted at different ſeaſons; but the reſult in general was, that what ſhould ſeem the beſt methods ſucceeded the worſt; and thoſe pieces where many labourers were employed, and the acorns planted before winter, were much thinner of young oaks, than thoſe where the leaſt labour had been beſtowed upon the ground, and where the acorns had been planted in the ſpring; but thoſe places which ſucceeded beſt from the ſowing, were thoſe which had the acorns planted in holes made by a pickax, without any preceding culture of the ground. And thoſe where the acorns had only been laid upon the earth, under the graſs, afforded a great number of vigorous young trees, though the greater part had been carried away by birds, and other devouring animals. Thoſe ſpots of ground where the acorns were ſet ſix inches deep, were much worſe furniſhed with young ſhoots, than thoſe where they had been buried but at an inch deep; and in ſome places where they were buried at a foot deep, not one ſhoot appeared, though in others where they had been buried at nine inches there were many.

Thoſe acorns which had been ſteeped for eight or nine days in wine lees, and in the water of the common ſewers, appeared out of the ground much earlier than thoſe which were put in without this previous management.

But the moſt ſucceſsful of all the trials was that of planting in the ſpring ſuch acorns as had been ſown together in another place, and had time to ſhoot there; of theſe ſcarce any failed, and the plantation was perfectly flouriſhing, though the growth of theſe young ſhoots was not ſo quick and vigorous as thoſe of the acorns which had remained, when firſt ſown; which was probably owing to the injury the tender radicles received in tranſplanting.

Thus ſucceeded the experiments by ſowing, while, of thoſe made by planting young trees, ſuch as had been brought out of woods, and places under covert, ſucceeded much worſe than thoſe which had grown in more expoſed places.

The young trees of the ſeveral parts of the plantation kept on their growth in the manner they had begun to ſhoot, thoſe of the more laboured parts continuing more weak, and lower than thoſe of the leſs laboured.

Thus were a number of neceſſary experiments carefully tried, and the reſult of the whole was, that to make a plantation of oaks, on a ſoil of the common clayey or loamy kind, the moſt ſucceſsful method is this: the acorns muſt be preſerved during the winter in the earth in this manner: let there be made a bed of earth ſix inches deep, on this place a layer of acorns two inches deep, over theſe lay a bed of another half foot of earth, over that another layer of acorns, and ſo on ſucceſſively, till as many are employed as there will be occaſion for; the whole is then to be covered with a foot depth of earth, to preſerve all from the froſt. In the beginning of March, theſe beds are to be opened, and the acorns which will by that time have ſhot out, and are then in reality ſo many young oaks, are to be planted out at a foot diſtance each, and the ſucceſs of a plantation of this kind need not be feared. This is a manner of planting that is done at a ſmall expence, and even that might be in a great meaſure ſpared, were it not for the birds and other devouring animals; ſince, could the acorns be defended from theſe, they might be only laid on the ſurface of the ground under the graſs in autumn, and they would infallibly ſhew themſelves in ſo many young oaks the ſucceeding ſpring.

It is eaſy to continue the carrying the acorns, when taken out of their winter's bed, to the place where they are to be planted, without doing them much injury; and the ſmall ſtop the tranſplanting puts to their growth, is in reality rather an advantage than an injury; ſince it only retards the young ſhoots for about three weeks, or leſs than that: and by that means ſecures them from the few cold mornings that may be expected about the time of their natural appearance.

TREFOIL, a genus of plants, the flower of which has a tubulous permanent empalement of one leaf: it is of the butterfly kind, drying in the empalement. The ſtandard is reflexed, the wings are ſhorter than the ſtandard, and the keel is ſhorter than the wings: it has ten ſtamina, nine are joined, and one is ſeparate, terminated by ſingle ſummits, and an almoſt oval germen ſupporting an awl-ſhaped ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a ſhort pod with one valve, containing a few roundiſh ſeeds.

Mr. Miller enumerates twelve different ſpecies of trefoil, the firſt of which is well known in England by the name of red clover; and the manner of cultivating this plant has been already deſcribed under the article CLOVER.

The ſecond ſort, namely, the white Dutch clover, grows naturally in moſt of the paſtures in England, and is generally known among the country people by the name of white honey ſuckle.

This is an abiding plant; whoſe branches trail upon the ground, and ſend out roots from every joint, ſo that it thickens and makes the cloſeſt ſward of any of the ſown graſſes; and it is the ſweeteſt feed for all ſorts of cattle yet known: therefore when land is deſigned to be laid down for paſture, with intent to continue ſo, it ſhould be ſown with the ſeeds of this plant. The uſual allowance of this ſeed is eight pounds to one acre of land; but this ſhould never be ſown with corn, for if there is a crop of corn, the graſs will be ſo weak under it, as to be ſcarce worth ſtanding; but ſuch is the covetouſneſs of moſt farmers, that they will not be prevailed on to alter their old cuſtom of laying down their grounds with a crop of corn, though they loſe twice the value of their corn by the poorneſs of the graſs, which will never come to a good ſward, and one whole ſeaſon is alſo loſt; for if this ſeed is ſown in the ſpring without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a much better after-feed for cattle the following autumn and winter, than

the graſs which is ſown with corn will produce the ſecond year. The ſeed of this ſort may alſo be ſown in autumn, and this autumnal ſowing, if the ſeeds grow kindly, will afford a good early crop of hay the following ſpring; and if, after the hay is taken off the land, the ground be well rolled, it will cauſe the clover to mat cloſe upon the ground, and become a thick ſward.

The ſeeds of this white Dutch clover is annually imported from Flanders, by way of Holland, whence it received the name of Dutch clover; not that it is more a native of that country than of this, for it is very common in moiſt paſtures, in every county in England: but the ſeeds were never collected for ſowing in this country till of late years; nor are there many perſons here, even now, who ſave this ſeed, though it may be done if the ſame method, as is practiſed for the red clover, be taken with this ſort; it ſhould therefore be recommended to every farmer, who is deſirous of improving his land, to ſow carefully an acre or two of this white clover for ſeed, which will ſave him the expence of buying for ſome years, when the price is great; and there will be a ſure market for any quantity he may have to ſpare.

The third ſort, namely hop-clover, called by ſome yellow meadow trefoil, grows naturally among the graſs in the upland paſtures of this country; but the ſeeds are frequently ſold in the ſhops, and are by many mixed with the other ſorts of clover and graſs-ſeeds, for laying down ground to paſture. This plant grows with upright branching ſtalks about a foot high, garniſhed with trifoliate leaves, whoſe lobes are oblong and heart-ſhaped, but reverſed, the narrow point joining the foot ſtalks. The flowers, which are yellow, grow from the wings of the ſtalk, upon long foot-ſtalks, collected into oval imbricated heads, having naked impalements lying over each other like ſcales, ſomewhat like the flowers of hops, from whence the plant had the name of hop-clover. But there are two ſorts of this clover, which grow naturally in England. The other is a much ſmaller plant than this, and generally known by the name of none-ſuch, or yellow hop-trefoil.

The hop-clover is ſtrongly recommended by the following circumſtances. 1. It not only grows, but flouriſhes on the moſt barren ſands, and therefore muſt be a very proper graſs to cultivate on ſuch unfertile ſoils, where any other graſs that is worth notice will not grow at all. 2. It is not apt to ſwell cattle, as the red-clover does. 3. In good ground it will continue long, and bear a very good ſeed or crop, as Mr. Tull, though prejudiced againſt clovers, confeſſes; and, by its flouriſhing both on ſands and clay, which have not been ploughed for many years, it ſeems likely to continue long in any ſoil.

The fifth ſort grows naturally on chalky lands in many parts of England; and in ſome countries the ſeed is ſown after the ſame manner as the common red clover, eſpecially on chalky ground, where it will thrive, and produce a better crop than clover. The ſtalks of this are hairy, and grow erect to the height of two feet or more, garniſhed with trifoliate leaves, ſtanding upon long foot-ſtalks, whoſe lobes are longer than thoſe of the red-clover, and have no marks of white; they are of a yellowiſh green colour, and are covered with ſoft hairs. The flowers grow in oval ſpikes at the end of the branches; they are of a pale copper colour; their petals are long and tubulous, but the brim is divided into two lips, as the other ſorts.

This is known by the title of trefoil, in the places where it is cultivated; but the ſeedſmen ſell the hop-clover by that name, ſo they make no diſtinction between this, the hop-clover, and none-ſuch; therefore, by which of theſe three titles the ſeeds are bought, they prove the ſame.

This ſort of trefoil is much cultivated in that part of Eſſex which borders on Cambridgeſhire.

The ſixth ſort grows naturally in Spain and Italy; this has upright ſtalks near two feet high, which are hairy, garniſhed with trifoliate leaves, having roundiſh lobes, which are ſawed at their points. The flowers are produced at the top of the ſtalk in long, obtuſe, hairy ſpikes, of a bright red colour, ſo make a pretty appearance during their continuance. It is an annual plant, ſo is not proper for ſowing as fodder.

The ſeventh ſort is an annual plant, which grows naturally in the South of France and Italy; it riſes with a ſtrong ſmooth ſtalk near three feet high, garniſhed with trifoliate leaves, whoſe lobes are two inches and a half long, and near a quarter broad, ſtanding upon long foot-ſtalks, which are embraced by ſtipulæ or ſheaths their whole length. The flowers are produced at the top of the ſtalks in very long ſpikes; they are of a beautiful red colour, ſo make a fine appearance. It flowers in July, and the ſeeds ripen in autumn.

The eighth ſort grows naturally in Spain and Italy; this riſes with a ſlender ſtiff ſtalk near two feet high, garniſhed with trifoliate leaves, whoſe lobes are very narrow and hairy. The flowers are produced at the top of the ſtalks in oblong conical ſpikes; the indentures of their empalements end in long briſtly hairs, which are almoſt equal in length; the ſpikes are hairy, and the flowers of a pale red colour.

The ninth ſort is the common hare's foot trefoil, which grows naturally upon dry gravelly land in moſt parts of England, and is a ſure indication of the ſterility of the ſoil, for it is rarely ſeen upon good ground. This plant is ſeldom eat by cattle, ſo is unfit for paſture, and is only mentioned here becauſe it is ſometimes uſed in medicine; it is an annual plant, whoſe root decays ſoon after it has perfected ſeeds.

The tenth ſort grows naturally on arable land in many parts of England; this has trailing ſtalks, which put out roots at their joints. The leaves ſtand upon long ſlender foot-ſtalks; the lobes are roundiſh, and ſawed on their edges; the flowers are collected in roundiſh heads, ſtanding upon ſlender foot-ſtalks, which riſe from the wings of the ſtalks; theſe have bladdery empalements, which terminate in two teeth. When theſe lie on the ground, their globular heads, having a little bluſh of red on their upper ſide toward the ſun, and the other part being white, have a great reſemblance of ſtrawberries, and from thence it was called ſtrawberry trefoil.

Theſe ſorts are preſerved in botanic gardens for variety; they are eaſily propagated by ſeeds, which may be ſown on an open bed of ground, either in autumn or ſpring.

The plants which come up in autumn, will grow much larger, and flower earlier in the ſummer than thoſe which are ſown in the ſpring, ſo from thoſe good ſeeds may be always obtained, whereas the others ſometimes miſcarry. When the plants come up, they require no other care than to keep them clean from weeds, and thin them where they are too cloſe.

The eleventh ſort is the common melilot, which is uſed in medicine, and has been already deſcribed under the article MELILOT, which ſee.

The twelfth ſort grows naturally in Bohemia and Auſtria, but has been long cultivated in England as a medicinal plant, though at preſent it is rarely uſed; it is annual. The ſtalks are large, hollow, and channelled; they riſe about a foot high, garniſhed with trifoliate leaves, whoſe lobes are oval, and ſlightly ſawed on their edges, ſtanding upon pretty long foot-ſtalks. The flowers are collected in oblong ſpikes, which ſtand upon very long foot-ſtalks, ſpringing from the wings of the ſtalk at every joint; they are of a pale blue colour, ſhaped like thoſe of the common melilot; theſe appear in June and July, and are ſucceeded by ſmall yellow ſeeds, of a kidney ſhape, two or three being included in each ſhort pod. The whole plant has a very ſtrong ſcent like that of fenugreek, and periſhes ſoon after the ſeeds are ripe. *Miller's Gard. Dict.*

TRENCH, a furrow cut in the earth for draining land. *See the articles* BOG and DRAINING.

TRENDLE, any thing that turns round.

To TREFALLOW, to plough land the third time before ſowing.

TROUGH, a long veſſel for holding water, &c.

TRUG, or TRUGG, a hod for mortar.

TRUNDLE, a ſort of carriage with low wheels, for carrying heavy and cumberſome loads.

TRUNK, the ſtem or body of a tree; or the part between the ground and the place where it divides into branches.

TRUSS, a bundle of hay, ſtraw, &c.

A truſs of hay muſt contain fifty-ſix pounds, or half a hundred weight; thirty-ſix truſſes make a load. In June, July, and Auguſt, a truſs of new hay muſt weigh ſixty pounds.

TUMBREL, a dung-cart.

TUMOUR, a preternatural ſwelling or eminence riſing in any part of a horſe, and ariſes either from external injuries, or internal cauſes.

Swellings cauſed by external accidents, as blows and bruiſes, ſhould at firſt be treated with reſtringents; thus, let the part be bathed frequently with hot vinegar or verjuice, and, where it will admit of bandage, let a flannel wetted with the ſame be rowled on: if by this method the ſwelling does not ſubſide, apply, eſpecially on the legs, a poultice with red wine lees, ſtrong beer grounds, and oatmeal, or with vinegar, oil, and oatmeal; either of theſe may be continued twice a day, after bathing, till the ſwelling abates; when, in order to diſperſe it intirely, the vinegar ſhould be changed for camphorated ſpirit of wine, to four ounces of which, may be added one of ſpirit of ſal armoniac; or it may be bathed with a mixture of two ounces of crude ſal armoniac boiled in a quart of chamber-lye, twice a day, and rags dipped in the ſame may be rowled on.

Fomentation made by boiling wormwood, bay-leaves, and roſemary, and adding a proper quantity of ſpirits, are often of great ſervice to thin the juices, and fit them for tranſpiration; eſpecially if the injury has affected the joints.

But in bruiſes, where the extravaſated blood will not by theſe means be diſperſed, the ſhorteſt way is to open the ſkin, and let out the grumes.

Critical tumours, or ſwellings which terminate fevers, ſhould by no means be diſperſed; except when they fall on the paſtern or coffin joint, ſo as to endanger them: in this caſe the diſcutient fomentation ſhould be applied three or four times a day, and a cloth or flannel frequently wrung out of the ſame ſhould be bound on, in order to keep the joint continually breathing.

But if the ſwelling fixes under the jaws, behind the ears, on the poll, withers, or in the groins and ſheath, &c. it ſhould be encouraged and forwarded by ripening poultices, wherever they can be applied; oatmeal boiled ſoft in milk, to which a proper quantity of oil and lard is added, may anſwer this purpoſe; or the poultice recommended in treating of the ſtrangles: theſe muſt be applied twice a day, till the matter is perceived to fluctuate under the fingers, when it ought to be let out; for which purpoſe, let the tumour be opened with a knife or ſtrong launcet, the whole length of the ſwelling, if it can be done ſafely, for nothing contributes ſo much to a kind healing, as the matter's having a free diſcharge, and the opening being big enough to dreſs to the bottom.

Pledgits of tow ſpread with black or yellow baſilicon (or the wound ointment) and dipped in the ſame, melted down with a fifth part of oil of turpentine, ſhould be applied to the bottom of the ſore, and filled up lightly with the ſame, without cramming; it may be thus dreſſed once or twice a day, if the diſcharge is great, till a proper digeſtion is procured, when it ſhould be changed for pledgits ſpread with the red precipitate ointment, applied in the ſame manner.

Should the ſore not digeſt kindly, but run a thin water and look pale, foment as often as you dreſs, with the above fomentation; and apply over your dreſſing the ſtrong beer poultice, and continue this method till the matter grows thick, and the ſore florid.

The following ointments will generally anſwer your expectations in all common caſes, and may be prepared without, as well as with, the verdigreaſe.

Take Venice turpentine and bees wax, of each a pound; oil of olives one pound and a half; yellow roſin twelve ounces: when melted together, two or three ounces of verdigreaſe finely powdered may be ſtirred in, and kept ſo till cold, to prevent its ſubſiding.

Take of yellow baſilicon, or the above ointment without verdigreaſe, four ounces; and red precipitate finely powdered half an ounce: mix them together cold, with a knife or ſpatula.

This laſt applied early, will prevent a fungus, or proud fleſh, from ſhooting out; for if you dreſs too long with the above digeſtive, the fungus will riſe faſt, and give ſome trouble to ſuppreſs it; when it will be neceſſary to waſh the ſore as often as you dreſs, with a ſolution of blue vitriol in water, or to ſprinkle it with burnt allum and precipitate. If theſe ſhould not be powerful enough, touch with a cauſtic, or waſh with the ſublimate water, made by diſſolving half an ounce of corroſive ſublimate in a pint of lime-water.

But this trouble may in a great meaſure be prevented, if the ſore is on a part where bandage can be applied with compreſſes of linen cloth: for even when theſe excreſcences regerminate, as it were, under the knife, and ſpring up in ſpite of the cauſtics above-mentioned, they are to be ſubdued by moderate compreſſion made on the ſprouting fibres, by theſe means.

Authors on farriery have in general given very proper receipts to anſwer every intention of this kind by medicines; but as they have not, I think, laid down ſufficient rules for their application in thoſe caſes where they are moſt wanted, I hope the following general directions will not be unacceptable; as the difficulty in healing ſome kinds of ſores ariſes frequently from the unſkilful manner of dreſſing them.

It may be neceſſary then to obſerve here once for all, that the cures of moſt ſores are effected by the ſimpleſt methods, and that it is often of much more conſequence to know how to dreſs a ſore, than what to dreſs it with; and in this conſiſts indeed the chief art of this branch of ſurgery; for the moſt eminent in that profeſſion have long ſince diſcovered, that variety of ointments and ſalves are unneceſſary in the cure of moſt wounds and ſores, and they have accordingly diſcarded the greateſt part, formerly in repute for that purpoſe; repeated obſervations having taught them, that after the digeſtion, nature is generally diſpoſed to heal up the wound faſt enough herſelf, and that the ſurgeon's chief care is to prevent a luxuriancy, commonly called proud fleſh; which all ointments wherein lard or oil enters, are but too prone to encourage, as they keep the fibres too lax and ſupple; and which dry lint alone, early applied, as eaſily prevents, by its abſorbing quality, and light compreſſion on the ſprouting fibres.

Thus if a hollow wound or ſore is crammed with tents, or the dreſſings are applied too hard, the tender ſhoots of fleſh from the bottom are prevented puſhing up; and the ſides of the ſore in time from this diſtention may grow horney, and turn fiſtulous; nor has the matter by this method a free diſcharge.

On the other hand, if ſores of any depth are dreſſed ſuperficially, the external parts being more diſpoſed to heal and come together than the internal, they will fall into contact, or heal too ſoon; and the ſore not filling up properly from the bottom, will break out afreſh.

Hence we may juſtly conceive how little ſtreſs is to be laid on famous ointments, or family ſalves, unſkilfully applied; for unleſs this due medium is obſerved, or obtained in the dreſſing, no hollow ſore can heal up properly.

I thought it neceſſary to be a little explicit on this head, as gentlemen ſo frequently complain of being diſappointed in their cures, notwithſtanding the excellency of their ointment, or balſam; and to convince them that leſs confidence ſhould be put in theſe favourite medicines than is generally imagined; for where the habit is ſound, and the blood and juices in good condition, there are few ſimple dreſſings that will not ſucceed; and when otherwiſe, the moſt pompous will not avail, till theſe are rectified by proper internal medicines.

As ſoon then as a good digeſtion is procured (which is known by the thickneſs and whiteneſs of the matter diſcharged, and the florid red colour at the bottom of the ſore) let the dreſſings be changed for the precipitate medicine; or the ſore may be filled up with dry lint alone, or dipped in lime-water with a little honey and tincture of myrrh, or brandy: about a fifth part of the latter to one of the former; a pledgit of lint dipped in this mixture ſhould alſo be applied to the bottom of the ſore, which ſhould be filled up with others to the ſurface or edges, but not crammed in too hard, as before obſerved, nor yet applied too looſely.

By this method, the ſore would incarn, or heal up properly, and ſoft ſpungy fleſh would be prevented, or ſuppreſſed in time; whereas when ointments or ſalves are too long continued, a fungus or proud fleſh, is thereby ſo encouraged in its growth, that it requires ſome time to deſtroy and eat it down again: a proper compreſs of cloth, and a linen roller is abſolutely neceſſary both for this purpoſe, and to ſecure on the dreſſings, wherever they can conveniently be applied. *Bartlet's Farriery, page* 236.

TUPP, a ram.

TUPPING-TIME, ramming time.

TURF, a blackiſh, ſulphureous earth, uſed in ſeveral parts of England, Holland, and Flanders, as fewel.

In Flanders, their turf is dry or pared from off the ſurface of the earth, and cut in form of bricks. The ſedge, or ſpecies of graſs growing very thick on the turf earth, contributes greatly, when dry, to the maintenance of the fire.

The Dutch take their turf from the bottom of the dykes or canals which run acroſs moſt of their lands; by which means they not only ſupply the defect of wood, which is very great in moſt of the United Provinces, but alſo keep their dykes clear and navigable: this turf earth is very black. As they take it up from the bottom of the dykes, they ſpread it about the edges of ſuch a thickneſs, as that it may be reduced to three inches when moderately dried. In this condition they cut it into pieces of turfs ſeven or eight inches long, and three broad, and, to complete the drying, lay them up in heaps, and at laſt in ſtacks.

In the north of England, Scotland, &c. turf is dug out of ſoft, moiſt, rotten earth, called peatmoſs. They dig horizontally from the ſurface, to the depth of about four feet, with a ſpade, which at once faſhions and takes them out in parallelopipeds nine or ten inches long, and three ſquare; which are ſpread on the ground to drain as faſt as dug; and then ſet up an end three or four againſt each other, for the wind to blow through them; and at laſt they are ſtacked or houſed. The pits or dykes in a few years fill up again, and afford a freſh crop.

TURF-ASHES. *See the article* ASHES.

TURF-BOGS. *See* BOG, MOOR, and MOOSS.

TURFING-SPADE, an inſtrument uſed to under-cut the turf, after it is marked out with the plough.

TURKEY, the name of a well known fowl, reared in many parts of England.

"Moſt of our houſewives, ſays a Swediſh author on huſbandry, have long deſpaired of ſucceſs in rearing turkeys, and complained that the profit rarely indemnifies them for their trouble and loſs of time: whereas, continues he, little more is to be done than to plunge the chick into a veſſel of cold water, the very hour, or if that cannot be, the day it is hatched, forcing it to ſwallow one whole pepper-corn, and then reſtoring it to its mother. From that time it will become hardy, and fear the cold no more than a hen's chick. After which it muſt be remembered that theſe uſeful creatures are ſubject to one particular malady whilſt they are young, which carries them off in a few days. When they begin to droop, examine carefully the feathers on their rump, and you will find two or three, whoſe quill part is filled with blood. Upon drawing theſe the chick recovers, and after that requires no other care than what is commonly beſtowed on poultry that range the court-yard.

"Theſe articles are too true to be denied; and in proof of the ſucceſs, three pariſhes in Sweden have, for many years, gained ſeveral hundred pounds by rearing and ſelling turkeys." *Rural Oeconomy, page* 739.

TURNEP, or *Turnip*, an eſculent plant, of which there are three ſpecies enumerated by Miller. The firſt is the turnip which is commonly cultivated in the fields, of which there are the following varieties, viz. the round red or purple topped turnip, the green topped turnip, the yellow turnip, the black rooted turnip, and the early Dutch turnip. The laſt ſort is commonly ſown early in the ſpring, to ſupply the markets in May and June, but is never cultivated for a general crop. The red rooted turnip was formerly more cultivated in England than at preſent; for ſince the large green topped turnip has been introduced, all the ſkillful farmers prefer it to the other ſorts; the roots of the green will grow to a large ſize, and continue good much longer than the other ſorts. The next to this is the red or purple topped turnip, which will alſo grow large, and is extremely good for ſome time; but the roots of this will become ſtringy much ſooner than thoſe of the green topped. The long rooted turnip, the yellow turnip, and the blackiſh rooted turnip, are now rarely cultivated in England, neither of them being ſo good for the table or for feed, as the red and green topped turnip, though there are ſome few perſons who ſow them for the ſake of variety.

The French turnip is not much cultivated in England, but in France and Holland they are in great eſteem, eſpecially for ſoups; their roots being ſmall, are boiled whole in the ſoup, and ſo ſerved up to the table; theſe muſt be uſed while they are young, otherwiſe they will become rank and ſtringy.

Theſe are ſuppoſed to be only varieties, which have accidentally been obtained from ſeeds, therefore I have not enumerated them as diſtinct ſpecies; but yet I am certain they are conſtant, where care is taken in the ſaving of their ſeeds not to ſuffer any mixture to ſtand for ſeeds: I have ſown of three or four ſorts ſeveral years, and have always found them retain their differences; however, it is not eaſy to determine if ſome of theſe were not by culture firſt obtained from ſeeds of the common white turnip. The yellow turnip ſeems moſt unlikely to have been an accidental variety, for I have never known this alter, and the roots are yellow within, whereas all the other have white fleſh, notwithſtanding their outſides are of very different colours.

The long rooted turnip is, I think, a diſtinct ſpecies, the form of the root, and its manner of growth being totally different from the other ſorts. I have ſeen theſe roots as long as thoſe of the parſnip, and nearly of the ſame ſhape; theſe run deep into the ground, ſo are unfit for feeding of cattle; and unleſs they are uſed very young, become ſtrong, ſo not proper for the table, which has occaſioned their being rejected of late years.

The green topped turnip grows above ground more than any of the other, which renders it preferable for feeding of cattle; and being the ſofteſt and ſweeteſt root when grown large of any of the kinds, is moſt eſteemed for the table; but in very ſevere winters they are in greater danger of ſuffering by froſt, than thoſe whoſe roots lie more in the ground, eſpecially if they are not covered by ſnow; for when they are frequently hard frozen and thawed, it cauſes them to rot ſooner than thoſe whoſe fleſh is leſs tender and ſweet. I have ſeen the roots of this ſort, which were more than a foot diameter, boiled, and were as ſweet and tender, as any of the ſmalleſt roots.

Turnips delight in a light, ſandy, loamy ſoil, which muſt not be rich; for in a rich ſoil they grow rank and are ſticky, but if it be moiſt they will thrive the better in ſummer, eſpecially in freſh land, where they are always ſweeter them upon an old worn-out or a rich ſoil.

The common ſeaſon for ſowing of turnips, is any time from the beginning of June to the middle of Auguſt, or a little later; though it is not adviſeable to ſow them much after, becauſe, if the autumn ſhould not prove very mild, they will not have time to apple before winter, nor will the roots of thoſe which are ſown after the middle of July, grow very large, unleſs the froſt keeps off long in autumn. But, notwithſtanding this is the general ſeaſon in which the greateſt part of turnips are ſown in the country, yet, about London, they are ſown ſucceſſively from March to Auguſt, by thoſe who propagate them to ſupply the markets with their roots; but there is a great hazard of loſing thoſe which are ſown early in the year, if the ſeaſon ſhould prove dry, by the fly, which will devour whole fields of this plant while young; ſo that where a ſmall quantity for the ſupply of a family is wanted, it will be abſolutely neceſſary to water them in dry weather; and where a perſon ſows thoſe ſeeds in April and May, it ſhould always be upon a moiſt ſoil, otherwiſe they ſeldom come to good, the heat of the weather at that ſeaſon being too great for them upon a dry ſoil; but thoſe which are ſown towards the middle or latter end of June, commonly receive ſome refreſhing ſhowers to bring them forward; without which, it is very common to have them all deſtroyed.

Theſe ſeeds ſhould always be ſown upon an open ſpot of ground; for if they are near hedges, walls, buildings, or trees, they will draw up, and be very long topped, but their roots will not grow to any ſize.

They are ſown in great plenty in the fields near London, not only for the uſe of the kitchen, but for food for cattle in winter, when there is a ſcarcity of other food; and this way is become a great improvement to barren ſandy lands, particularly in Norfolk, where, by the culture of turnips, many perſons have doubled the yearly value of their ground.

The land upon which this ſeed is ſown, ſhould be ploughed in April, and twy-fallowed in May, that is once more ploughed and twice well harrowed, and made very fine; then the ſeed ſhould be ſown pretty thin; for it being ſmall, a little will ſow a large piece of ground; one pound is the common allowance for an acre of land. The ſeed muſt be harrowed in as ſoon as it is ſown, with a ſhort-tined harrow, and the ground rolled with a wooden roll, to break the clods, and make the ſurface even. In ten days or a fortnight after ſowing, the plants will come up; at which time, if the ſeaſon ſhould prove dry, they will be in great danger of being deſtroyed by the fly; but if it ſo happen, the ground muſt be ſowed again, for the ſeed being cheap, the chief expence is the labour; but the ground ſhould be firſt harrowed to looſen it, eſpecially if it is ſtiff land.

When the plants have got four or five leaves, they ſhould be hoed to deſtroy the weeds, and to cut up the plants where they are too thick, leaving the remaining ones about ſix or eight inches aſunder each way, which will be room enough for the plants to ſtand for the firſt hoeing; the ſooner this is performed, when the plants have four leaves, the better they will thrive; but in the ſecond hoeing, which muſt be performed about a month after the firſt, they ſhould be cut up, ſo as that the remaining plants may ſtand fourteen or ſixteen inches diſtance, or more, eſpecially if they are deſigned for feeding of

catttle;

cattle; for where the plants are allowed a good diſtance, the roots will be proportionably large; ſo that what is loſt in number, will be over-gained by their bulk, which is what I have often obſerved. But in ſuch places where they are ſown for the uſe of the kitchen, they need not be left at a greater diſtance than ten inches or a foot, becauſe large roots are not ſo generally eſteemed for the table.

It is not many years ſince the practice of ſowing turnips for feeding of cattle, has been of general uſe; how it happened that this improvement ſhould have been ſo long neglected in every part of Europe, is not eaſy to determine, ſince it is very plain, that this piece of huſbandry was known to the ancients. For Columella, in treating of the ſeveral kinds of vegetables which are proper for the fields, recommends the cultivating rape in plenty; becauſe, ſays he, thoſe roots which are not wanted for the table, will be eaten by the cattle: yet this plant was not much cultivated in the fields till within the laſt ſixty or ſeventy years; nor is the true method of cultivating turnips yet known, or at leaſt not practiſed, in ſome of the diſtant counties of England, at this time. For in many places the ſeed is ſown with barley in the ſpring, and thoſe plants which come up, and live till the barley is cut, produce a little green for the ſheep to pick up, but never have any roots. In other places, where the turnip ſeed is ſown by itſelf, the method of hoeing them is not underſtood; ſo that weeds and turnips are permitted to grow together; and where the turnips come up thick in patches, they are never thinned, ſo that they draw up to have long leaves, but never can have good roots, which is the principal part of the plant, therefore ſhould be chiefly attended to.

The general method now practiſed in England, for cultivating this plant in the fields, is the ſame as is practiſed by the farming gardeners, who ſupply the London markets with theſe roots, and is the ſame as before directed. But it is only within the compaſs of a few years, that the country people have been acquainted with the method of hoeing them; ſo that the farmers formerly employed gardeners, who had been bred up in the kitchen gardens, to perform this work; but it is now performed by many country labourers, by which means that practice is loſt to the kitchen gardeners; the labourers doing it much cheaper.

There has alſo been another method practiſed very lately, by ſome very curious farmers, in cultivating of turnips, which is by ſowing the ſeed in rows, with the drill-plough. In ſome places the rows are ſown three feet aſunder, in others four, in ſome five, and ſome ſix. The latter has been recommended by ſome, as the moſt proper diſtance; and although the intervals are ſo large, yet the crop produced on an acre has been much greater than upon the ſame quantity of land, where the rows have been but half this diſtance; and upon all the fields which have been tilled, the crops have greatly exceeded thoſe which have been hand-hoed. The late lord viſcount Townſhend was at the expence of making the trial of theſe two different methods of huſbandry, with the greateſt care, by equally dividing the ſame fields into different lands, which were alternately ſown in drills, and the intermediate lands in broad-caſt. The latter were hoed by hand, in the common method, and the other cultivated by the hoeing-plough; and when the roots were fully grown, his lordſhip had an equal quantity of land, which had been ſowed in the different methods, meaſured, and the roots drawn up and weighed; thoſe roots which had been cultivated by the plough, were ſo much larger than the other, that the crop of one acre weighed a ton and half more than that of an acre in the other huſbandry.

But when the turnips are ſown in drills, they will require to be hoed by hand, to ſeparate and cut out the plants, where they are too near together in the rows; as alſo to cut up the weeds between the plants, where the plough cannot reach them. If this is carefully performed, the ploughing of the intervals will encourage the growth of the roots, by thus ſtirring of the ground, and make it much better prepared for the crop of barley, or whatever elſe is ſown the following ſpring. This method of culture may be ſuppoſed to be more expenſive than that commonly practiſed, by thoſe unacquainted with it; but thoſe who have made trial of both, find the horſe-hoeing to be much the cheapeſt, and by far the beſt. For the country people, who are employed in hand-hoeing of turnips, are very apt to hurry over their work, ſo that half the weeds are left growing, and the plants are ſeldom ſingled out ſo well as they ſhould be; nor are they curious enough to diſtinguiſh the charlock, which is one of the moſt common weeds in arable land, from the turnips; ſo that about the middle of September, it is very common to ſee the fields of turnips full of the yellow flowers of the charlock. Now, in the horſe-hoeing, all the weeds in the intervals will be entirely deſtroyed; ſo that if a few plants in the rows of turnips ſhould be overlooked, they may be eaſily drawn when they appear viſible, and by this method the land will be ſooner and better cleaned from weeds.

The greateſt evil which attends a crop of turnips, is that of their being deſtroyed by the fly, which uſually happens ſoon after the plants come above-ground, or while they are in the ſeed-leaf; for, after they have put out their rough leaves pretty ſtrong, they will be paſt this danger. This always happens in dry weather; ſo that, if there ſhould be rain when the turnips come up, they will grow ſo faſt, as to be in a few days out of danger from the fly; and it hath been found, that thoſe, which have been ſown in drills, have eſcaped the fly much better than thoſe ſown in broad-caſt; but, if ſoot is ſown along the ſurface of each drill, it will be of great ſervice to keep off the fly, and a ſmall quantity of it will be ſufficient for a large field, where the drills only are to be covered.

Another danger of the crops being deſtroyed is from the caterpillars, which very often attack them, when they are grown ſo large as to have ſix or eight leaves on a plant. The ſureſt mothod of deſtroying theſe inſects, is to turn a large parcel of poultry into the field, which ſhould be kept hungry, and turned early in the morning into the field; theſe fowls will ſoon devour the inſects, and clear the turnips. To this evil the turnips, which are ſown in drills, are not ſo much expoſed; for as the ground between the rows will be kept ſtirred, the plants will be kept growing, ſo will not be in danger of ſuffering from theſe inſects, for the parent inſects never depoſit their eggs upon any plants which are in health; but as ſoon as they are ſtinted, they are immediately covered with the eggs of theſe inſects; and this holds in general with vegetables as with animals, who are ſeldom attacked by vermin when they are in perfect health; whereas, when they become unhealthy, they are ſoon overſpread with them; ſo that it is the diſeaſe which occaſions the vermin, and not the vermin the diſeaſe, as is commonly imagined.

When the turnips are ſown in drills, it will be the beſt way to plough between every other row at firſt, and ſome time after to plough the alternate intervals, by which method the plants will receive more benefit from the often ſtirring the ground than they would do, if all the intervals were hoed at one time; and plants will be in leſs danger of ſuffering from the earth being thrown up too high on ſome rows, while others may be left too bare of earth; but, when the earth has been thrown up on one ſide of the drill, it may be turned down again ſoon after the next interval is ploughed. This alternate moving of the earth will prepare the ground very well for the ſucceeding crop, and greatly improve the turnips; but, as the plough cannot well be drawn nearer to the drills than two or three inches, the remaining ground ſhould be forked to looſen the parts, and make way for the fibres of the roots to ſtrike out into the intervals; otherwiſe, if the land is ſtrong, it will become ſo hard in thoſe places which are not ſtirred, as to ſtint the growth of the turnips. This may be done at a ſmall expence; a good hand will perform a great deal of this work in a day, and, whoever will make the trial, will find their account in practiſing it, eſpecially on all ſtrong land, where the turnips are much more liable to ſuffer from the binding of the ground, than they will be on a looſe ſoil; but yet, in all ſorts of ground, it will be of great ſervice to practiſe this.

When the ground is thus ſtirred in every part, one ploughing will be ſufficient, after the turnips are eaten, for the ſowing of barley, or any other crop; ſo that there will be an advantage in this, when the turnips are kept late on the ground, as will often be the caſe, eſpeciallywhen they are cultivated for feeding of ewes, becauſe it is often the middle of April before the ground will be cleared; for late feed in the ſpring, before the natural graſs comes up, is the moſt wanted, where numbers of ſheep or ewes are maintained, and one acre of turnips will afford more feed than fifty acres of the beſt paſture at that ſeaſon.

In Norfolk and ſome other counties they cultivate great quantities of turnips for feeding of black cattle, which turn to great advantage to their farms, for hereby they procure a good dreſſing for their land; ſo that they have extraordinary good crops of barley upon thoſe lands, which would not have been worth the ploughing, if it had not been thus huſbanded.

When the turnips are fed off the ground, the cattle ſhould not be ſuffered to run over too much of the ground; for, if they are not confined by hurdles to as much as is ſufficient for them one day, the cattle will ſpoil three times the quantity of turnips as they can eat, ſo that it is very bad huſbandry to give them too much room: therefore the hurdles ſhould be every day removed forward, and if the turnips are drawn out of the ground before the cattle or ſheep are turned into the new incloſure, there will be leſs waſte made, for they will then eat up the whole roots; whereas, if they are turned upon the turnips growing, they will ſcoop the roots, and leave the rinds, which being hollow, the urine of the ſheep will lodge in them; ſo that, when they are forked out of the ground, the ſheep will not eat any of thoſe roots which are thus tainted.

I cannot omit taking notice of a common miſtake, which has generally prevailed with perſons who have not been well informed to the contrary, which is in relation to the mutton which is fatted with turnips, moſt people believing it to be rank and ill taſted; whereas it is a known fact, that the beſt mutton this country affords is all fatted on turnips, and that rank mutton, whoſe fat is yellow, is what the low marſhy lands of Lincolnſhire, and other rank paſtures, produce.

In order to ſave good turnip ſeeds, you ſhould tranſplant ſome of the faireſt roots in February, placing them at leaſt two feet aſunder each way, obſerving to keep the ground clear from weeds, until the turnips have ſpread ſo as to cover the ground, when they will prevent the weeds from growing. When the pods are formed, you ſhould carefully guard them againſt the birds, otherwiſe they will devour it, eſpecially when it is near ripe; at which time you ſhould either ſhoot the birds as they alight upon the ſeed, or lay ſome bird-limed twigs upon it, whereby ſome of them will be caught; and, if they are permitted to remain ſome time, and afterwards turned looſe, they will prevent the birds from coming thither again for ſome time, as I have experienced. When the ſeed is ripe it ſhould be cut up, and ſpread to dry in the ſun; after which it may be threſhed out, and preſerved for uſe.

There have been many receipts for preventing the fly taking turnips, but few of them deſerve notice; therefore I ſhall only mention two or three which I have ſeen tried with ſucceſs. The firſt was ſteeping the ſeeds in water with flour of brimſtone mixed, ſo as to make it ſtrong of the brimſtone: another was ſteeping it in water with a quantity of the juice of horſe-aloes mixed, both which have been found of uſe. The ſowing of ſoot or tobacco-duſt over the young plants, as ſoon as they appear above ground, has alſo been found very ſerviceable: in ſhort, whatever will add vigour to the young plants, will prevent their being deſtroyed by the fly, for thoſe never attack them, till they are ſtinted in their growth. *Miller's Gard. Dict.*

Mr. Liſle is inclined to think, that the beſt way to manage turnips, the ſeed of which, ſays he, is impatient of growth, and apt to burſt in too much wet, as alſo to corrupt, if the ground be ſo dry as only to give it a damp, but not wet enough to ſet it on growing, is, firſt to harrow the ground fine, after it has been brought to a perfect tilth by plowing, then to roll it with a roller big enough to break the little clods, if any ſuch remain, and ſo let it lie till the next rain; then, the ground being mellow, to ſow the ſeed, and harrow it in with ſhort-tined harrows, which may not open the ground too deep, nor bury the ſeed; then roll it again with a one-horſe roller, in order to keep the moiſture in the ground as deep as the ſeed may be: for the ſurface of the earth muſt not be dried before the ſeed can ſtrike root, which may be in twice twenty-four hours; and yet that ſurface muſt be ſo fine, and ſo lightly compreſſed, that the ſeed may ſpear through it. He takes the myſtery, as he calls it, of the ſucceſs or miſcarriage of a crop of turnips to conſiſt in theſe four things, viz. firſt, in the ſeeds not lying too deep; ſecondly, in its not lying too wet, which it cannot eaſily do if harrowed in ſhallow, for the ſurface of the earth is ſoon dry; thirdly, in its not lying too dry; and fourthly, in its lying in a fine bed. In another place, he tells us, that his gardener affirmed to him, that he had found turnip-ſeeds, which had been dropped by accident and covered over with earth in digging, freſh and good a year after, when the earth was turned back again, and that it has then grown and produced good turnips. The reaſon is, that every ſeed which

is

is buried ſo deep as not to be affected by the changes in the air, may remain in a ſound ſtate, and in a fit condition to vegetate, for many years, as hath been evinced by numbers of inſtances.

Mr. Duhamel adviſes after the two firſt hoeings a ſlight ploughing all over the field, with a plough that has no fins to the ſhare, as a ſpeedier and cheaper way to thin the plants: the turnips will not require any farther care. They will have attained their full ſize in October, before the froſts come, and ſhould then be taken up, ſtripped of their leaves, which may be given to cattle, and laid upon hurdles in a dry place, with a layer of dry ſand between each layer of turnips, which may be thus piled up, and which will keep very well in this condition, for the food of cattle during the winter. In Norfolk, they ſtow them in their barns, when intended for fattening of bullocks.

A dry ſeaſon is the beſt for hoeing turnips, becauſe neither the weeds nor the turnips hoed up then will be ſo apt to grow again: and Mr. Liſle ſuppoſes that care ſhould be taken to hoe up thoſe that are deepeſt rooted in the earth, and to leave thoſe that grow upon, and almoſt out of it, without much regarding their ſize; becauſe thoſe which lie on the ground, and have room to grow, will ſoon become the largeſt.

Some ſow turnips on their flax and hemp grounds, at the ſame time as they pluck up thoſe plants, and the ſeed is pretty well buried by the ſtirring thereby given to the earth. Others give their corn ſtubble only a ſlight plowing after harveſt, then ſow the turnips very thin, and harrow in the ſeed. Theſe methods do very well when the ground is in good tilth. Others again, ſow late turnips, merely for the ſake of their leaves, which they uſe as green feed, when they are about a foot high; and in this caſe they ſow the ſeed very thick.

An eaſy way to have two growths of turnips in the ſame field, is to ſow ſeed of the laſt gathering, and ſeed that is two years old; for this laſt is longer before it riſes, than the new: and an advantage attending this method, is, that the turnips, by riſing at different times, will have the better chance to eſcape the fly, or grub, which ſometimes deſtroy them entirely: for it has been obſerved, that theſe flies often come ſuddenly in great ſwarms, and eat up the turnips as faſt as they riſe; and that they ſometimes diſappear as ſuddenly; ſo that the turnips which riſe a few days after, in a neighbouring field, are not at all injured by them: conſequently, when the turnips of the ſame field riſe at different times, one or other may eſcape the ravage of theſe inſects; for they deſtroy them only while in their ſeed leaf.

The worm to which turnips are very liable may be guarded againſt, at leaſt in a great meaſure, as Mr. Liſle informs us, by liming the ground. This will alſo render them much ſweeter than they would otherwiſe be: and we are of opinion that freſh ſlacked lime ſtrewed over the ground when the turnip ſeed is ſown, will contribute greatly to preſerve the young plants from the fly. It is to the worm lodged in the root of the turnip, perhaps engendered from the egg of the fly, that Mr. Liſle imputes the diſtemper or diſeaſe in turnips, which the Norfolk farmers call the hanbery; ſo named from a like diſtemper in a horſe's heel. It is a watery excreſcence, formed probably by this inſect, in the ſame manner as galls are formed upon the leaves of the oak. In ſome years it takes off whole crops, and the turnips never thrive after it has begun to grow in them.

A gentleman, remarkable, among many other good qualities, for ſeveral excellent improvements which he has made in agriculture, tried with ſucceſs the following experiment, to preſerve turnips from the fly, and the better to ſecure their growth. He ſowed the ſeed in a nurſery, where there was leaſt danger of ſlugs or the fly, and where they might eaſily be watered in caſe of great drought, to make them grow the quicker. They remained in this nurſery, till they were large enough to be tranſplanted. By this means he gained ſome weeks longer, to perfect his fallow, or give a thorough plowing to ground which had borne a crop that ſeaſon. He tranſplanted his turnips into the field, and by planting them regularly at due diſtances, greatly leſſened the expence of hoeing; their regularity making it very eaſy to deſtroy the weeds from time to time, as they appeared.

In the ſecond part of the memoirs of the Society of Berne for the year 1762, the reverend Mr. Bertrand, not ſatisfied with even a ſcrupulous diſcharge of the duties of his clerical function, has inſtructed his pariſhioners, his country, and mankind, in the important ſubject of agriculture. The improving of light ſoils by the culture of turnips, is one of his objects: upon which he very judiciouſly obſerves, that though it be right to plough ſtiff lands before the winter, in order to their being mellowed by the froſt; yet as the fineſt and beſt parts of the ſoil will be in danger of being waſhed off, or carried down into the looſe earth underneath, when this is done in a light ground, or in mould which has a ſandy or gravelly bottom; it will be moſt adviſeable here, to turn the ſtubble down immediately after the corn has been taken off, and then to ſow turnips; becauſe their ſpreading leaves will ſhelter and ſecure the fine mould upon the ſurface, and keep the land in good heart, whilſt the earth will be looſened and divided by their roots, ſo that it will be rather fitter for a ſpring crop, than if it had lain uncultivated.

The chief uſe of turnips is, to feed cattle in the winter and ſpring, when there is a want of graſs for their paſture. Cows, oxen, and hogs, are very fond of this food, which fattens them, and increaſes the milk of the former. Sheep too eat it readily, and thrive upon it, when they have been uſed to it early; but they do not reliſh it when it has not been offered them till they are grown old: however, if they are kept faſting two or three days, moſt of them take to it, and when they have once taſted it, they become very fond of, and feed kindly upon it. In ſome places, they feed their lambs with turnips till the middle of April, though they then begin to run up to ſeed. Farmers chooſe rather to do this, than to let them hurt their clover, ſainfoin, lucern, &c. Some parboil them a little, at firſt, till their cattle, and particularly their ſheep, are accuſtomed to them: but a lamb only three weeks old, will, after it has once eaten of this food, ſcoop out a raw turnip with great glee.

Turnips, if not clean eaten, and well cleared off the ground, may take root again, run to ſeed, and do great damage to the enſuing crop. Mr. Liſle inſtances it in a gentleman of Berkſhire, who plowed up a turnip field in the ſpring, and ſowed it with peas: but the little dwarf turnips that were left behind, uneaten, notwithſtanding his plowing them up, took root again, run to ſeed in great quantities, and did much damage to his crop of peas.

The practice of turning a flock of ſheep, at random, into a large field of turnips, is very bad: for they will

then ſpoil more in a fortnight, than would keep them a whole winter. The beſt way, therefore, of feeding them with theſe roots, is, as Mr. Tull adviſes, and after him M. Duhamel, one or other of the three following methods, which are equally applicable to the drill, and to the common huſbandry.

The firſt is, to portion out the turnip ground, by incloſing with hurdles ſo much only as the ſheep can clear in one day; and ſo to advance the folds farther into the field every morning, until all be ſpent. But it is to be obſerved, that the ſheep never eat them clean this way, but take only the leaves and the heart of the turnip: ſo that great part of them remains in the earth. It is true that theſe fragments, if left there, rot, and become a manure: but when they are wanted for the food of the flock, and are to that end pulled up with iron crooks or forks made for this purpoſe, the ſheep do not reliſh, and conſequently eat but little of, theſe then dirty withered remains, tainted with their urine, dung, &c. nor can they nouriſh them ſo well as roots which are freſh and cleanly.

The ſecond method differs from the former only in pulling up the turnips ſo far as they are hurdled off, before the ſheep are turned in. They then eat them better, becauſe the food is freſh and in good condition. Beſides, as the whole turnips are pulled up more eaſily than their pieces can be, there is not ſuch waſte as in the other way. The turnips which grow next to the hurdles ſhould be thrown towards the middle of the ſpace hurdled off; becauſe they will be leſs liable to be trampled upon and ſpoiled there, than nearer to the hurdle, where the ſheep run about moſt, in ſearch of means, of eſcaping into the open field.

The third way is to pull up the turnips, and carry them into ſome other ground, and there ſpread them every day on a new place, where the ſheep will eat them up clean. This is done when there is land not far off, which has more need of dung than that where the turnips grow. The expence of carrying the turnips is compenſated by ſaving the price, or at leaſt the carriage and removing of the hurdles: only when the turnips are laid on a ſpot of graſs, as is frequently done in wet weather, the benefit of the dung and urine of the ſheep is loſt.

This method is requiſite when the field on which the turnips grow is wet; becauſe, 1. The ſheep would trample upon, and bury, part of the turnips, which would be loſt. 2. In treading that wet earth, they would poach it, and render it unfit for corn. 3. By this means, a field may be dunged, as we have juſt obſerved, which wants it more than that where the turnips grew. 4. This muſt neceſſarily be done, if wheat has been ſown in the alleys between the rows of turnips, according to the principles of the new huſbandry.

Turnips are always carried off the field, when they are intended to fatten the larger ſorts of cattle: and they ſhould be cut in pieces for them, leſt they choak themſelves with the whole ones. They are given morning and evening to ſtall-fed cattle, which in the intervals, eat likewiſe common fodder; but the turnips increaſe their appetite to ſuch a degree, that a middle ſized bullock, ſtalled for fattening, will conſume near two hundred pounds weight of theſe roots in twenty-four hours, beſides hay: whereas, if nothing but hay were given him, he would hardly eat half the quantity that he will with the turnips. A healthy bullock, in only good plight at the time of his beginning to be fed with turnips, will be very well fattened in three months.

Mr. Tull ſays he found by experience, that the beſt way of ſowing turnips is in ſingle rows, ſix feet aſunder. He ſowed them in double rows alſo at that diſtance, but they did not do well: and he likewiſe ſowed them in ſingle rows, with intervals of only three feet. Theſe laſt yielded a greater crop than a neighbouring field, which was ſown and managed in the common way: but neither the ſingle rows three feet aſunder, nor the double rows with intermediate diſtances of ſix feet, yielded, ſays he, half ſo much, as the ſingle rows ſix feet aſunder: from whence he concludes, that it is beſt to leave a ſpace of ſix feet between the rows; for that, if the alleys are well plowed, theſe turnips will thrive wonderfully, even though no other moiſture falls but the dew, which will ſink into the earth to their roots.

However, notwithſtanding Mr. Tull's experiment, M. Duhamel is for ſowing turnips in double rows, if the intervals are of ſix feet; or if they are ſown in ſingle rows, he would have theſe rows be but four feet aſunder, which is the ſpace left between the rows of vines in Languedoc, and which is there plowed with oxen.

An ounce of ſeed will ſow as much land when drilled, as a pound will in the common way: and if care be taken to diſtribute only the neceſſary quantity, a great deal of trouble will be ſaved in the hoeing of the plants, afterwards, to thin them. But it is eſſential to obſerve, we muſt again repeat it, that all roots, whether turnips, carrots, parſneps, parſly, or any other, always thrive beſt where there is a great depth of fine, light, well looſened mould. M. Duhamel trenched the whole of his kitchen-garden three feet deep: all his pot-herbs grew very fine, and his roots in particular were of a ſurprizing ſize.

Mr. Tull, by drilling his turnip ſeeds alternately at different depths in the earth, was ſure to ſucceed in one part or other, whether the ſeaſon was wet or dry. If wet, the ſeed ſlightly covered ſprouted firſt; and in dry ſeaſons, that which lay deepeſt was the firſt that roſe. By this means, and by mixing the ſeed, half new and half old, for the new always comes up ſooneſt, he had four comings up, which, as he obſerves, gave the plants ſo many chances to eſcape the fly.

If one was ſure of having rain immediately after the turnips are ſown, it would undoubtedly be right to ſow them very ſhallow: but if no rain happens, they are beſt deeper in the earth, becauſe they there meet with moiſture ſufficient to make them grow.

When the ſeaſon has been ſo kindly that all the ſeeds have grown, and the plants have not ſuffered by the fly or other inſects, they muſt be thinned early, that the ground may not be exhauſted by ſuch as are not intended to remain; for thoſe that are left ſhould be about a foot aſunder.

When the turnips ſown in drills thrive well, only each alternate alley need be hoed at one time, and the others a few days after; it being better to feed the plants gradually, by dividing the hoeings in this manner, than to give them a great deal of food at once, by hoeing all the alleys together, and afterwards leave them double the time without any culture at all. Another advantage attending this method is, that the plants will be the leſs liable to be killed by hot dry weather, and the leſs apt to be damaged by heavy rains. But it will not, indeed, ſo effectually deſtroy weeds,

weeds, which ought always to be a principal object of the husbandman's care, and which ever is one of the chief intentions of the New Husbandry. However, as all weeds are very apparent in the alleys, it is easy to extirpate them there; and as to those which may chance to be in the rows, the persons who thins the turnips may cut them up at the same time. He will there most easily distinguish the charlock from the turnips, especially when the leaves of these last are come to be about the breadth of a half crown.

All plants sown in single rows are greatly benefited by the alternate hoeing of the alleys between them: for, as M. Duhamel observes, 1. Four of these hoeings, which cost no more than two entire ones, are almost as beneficial to the plants as four complete hoeings. 2. A plant which finds a great deal of nourishment on one side, is the better able to thrive without receiving so much on the other. 3. If, in hoeing very near the plant, some of its roots are broke; those on the other side, not hoed, supply the wants of the plant, till the broken ones have made fresh shoots 4. The horse-hoe may therefore be brought very near to the turnips, without fear of hurting them; provided it do not force them out of the earth. 5. When a farmer has a great quantity of turnips to hoe, they are sooner supplied by this culture, than they possibly could be if all the alleys were to be hoed.

A furrow should not be left open near the turnips, while they are young; because the earth about them would in that case become too dry: but there is no danger of this in the autumn, when they are grown strong, and the earth is moist. Neither is it advisable to leave a furrow open near them during the winter; because they would be in danger of being hurt by the frost.

When these plants are grown large, and their roots are consequently pretty well extended, the hoe-plough need not come quite so near them as at first: nor is it necessary to hoe them at all, till they are about the bigness of one's finger's end.

One alternate hoeing, or which is the same thing, two half hoeings, will be sufficient when the turnips are sown late. But when they are sown early, and many weeds grow, one hoeing will not be enough.

By following this culture, M. Duhamel has seen turnips which weighed from sixteen to nineteen pounds; and we may depend on their weighing one with another twelve pounds a-piece in a good soil, which is a vast produce from an acre of land. Mr. Miller says, that one acre of turnips, thus properly cultivated, will afford more feed for sheep or ewes in the winter, than fifty acres of the best pasture at that season.

Another vast advantage which attends the sowing of turnips in rows, is, that instead of occupying the whole ground when it should be sowed with wheat, and sometimes even when it should be sown with spring-corn, as is frequently the case in the old way; they are no hindrance to either in the New Husbandry: for as the alleys are in good tilth, three rows of corn may be sown, seven inches asunder, between the rows of turnips; and when these roots are pulled up, the ground where they grew is hoed, and becomes the alleys between the beds of corn.

The best turnip seeds are obtained from the largest roots, which may either be transplanted for that purpose, or marked out in the field where they were sown. Those which are commonly sold in the shops, seldom produce the finest plants.

Experiments on turnips cultivated according to the New Husbandry.

In 1754, M. de Chateauvieux sowed turneps on beds, in two rows. They suffered greatly for want of rain, and none of them grew to the size they would have done in a more favourable season. Some of them weighed eight pounds; but their general weight was from three to four.

In 1755, M. de Chateauvieux sowed some beds with one row, some with two, and others with three rows. They were afterwards thinned, so that the plants stood a foot asunder in the rows. Those sown in one row were the largest, and, in general, the most equal. Some of them weighed fourteen pounds, and most of them from seven to eight. In the other rows, they did not weigh so much; but they were more numerous.

In consequence of these experiments, M. Duhamel, to whom they were communicated, makes the following striking calculation relative to the quantity of food which turnips will afford for cattle.

"Let a square whose side is 216 feet be formed into beds four feet wide, which is sufficient for one row of turnips. These will be 216 feet long, and consequently will contain that number of turnips, planted a foot asunder. These 216 multiplied by 54, the number of beds, will give 11664 turnips for the product of the square; and these multiplied by six, the supposed weight of each turnip, will give 69,984 pounds for the weight of all the turnips on this spot."

This may be looked upon as a very considerable crop; for it will be sufficient to stall-feed our bullocks during the three winter months, at the daily allowance of 200 pounds each: and yet there is reason to believe that the quantity will be doubled in a good year, as will be pretty evident to those who consider at how low a rate the medium weight of the turnips is here estimated.

In 1755, M. Duhamel sowed turnips in a field, on beds cultivated with the horse-hoe. They grew extremely fine; many of them being twenty-nine inches circumference.

The following account of the advantages of the drill husbandry in the culture of turnips, was sent by Mr. Willy, of South-Petherton, to the Society for the Encouragement of Arts, &c.

The generous method you have taken to promote useful knowledge must give every lover of his country the greatest pleasure, and incline him to do all in his power to increase it; 'tis with this view, and by the persuation of many friends, I presume to lay before you the following lines, hoping they may give you some satisfaction in respect to the difference betwixt the Old and New Husbandry.

I began husbandry in the year 1742, had always an inclination to drilling, and was at much trouble and expence in getting one instrument after another made for the purpose; but was often disappointed, and for some years was forced to lay by the thoughts of it. About eight years since a gentleman lent me Mr. Tull's treatise; I then got some new instruments made, which sowed very regularly, and since that time have sowed all my corn in rows. Several closes I ploughed in six furrow ridges, and sowed with three rows of wheat, plowing the intervals with a small full, drawn by one horse, and made it fit for wheat the next

next year; it generally took one third of the common quantity of ſeed, and in two years it yielded more than half as much again as the beſt crops in the common way did in one year; which, conſidering the ſmall expence of ſeed and labour, was ſome advantage, though not very great; but then it left the ground in very good order for the next crop of ſpring corn. I kept one cloſe, about two acres, four years to wheat in the ſame method; but the two laſt years did not anſwer to the two firſt, which makes me think Mr. Tull wrong, when he ſays, that plants of different natures are nouriſhed by the ſame ſort of food. I could give an account of the exact quantity produced in each year, but it would be tedious: upon the whole, I believe this method of ſowing wheat will be of no advantage except in poor ſtrong clays, where I apprehend it muſt exceed all others. But there are a few inconveniencies attending it; frequent ploughing the intervals is apt to make the wheat ſhoot freſh ears, which do not ripen with the others; and if any of the full ears when near ripe do but touch the freſh ploughed earth, ever ſo little wet will make them ſprout, and theſe will injure the whole crop; and I find it impoſſible to keep all up, as the rows are at ſo great a diſtance. But my method of drilling in the open fields, and which I intend to follow, is to put five rows about eight inches apart, on a ridge about five feet in breadth. This takes but two-thirds of the ſeed ſowed in the common way, and has always produced a better crop than the lands on each ſide of mine; this my neighbours are now convinced of, and ſeveral of them have drilled their wheat this ſeaſon: our ſoil, for the moſt part, is a deep heavy ſand.

I apprehend the principal advantage in drilling wheat is placing it at a proper depth, which I think is within two inches or thereabouts. I have obſerved, that the firſt motion of the wheat is by ſome roots, which in a little time run very deep; then it ſhoots up its blade; next it begins to form a head, about an inch under ground, from which come (very ſoon in a mild ſeaſon) the ſecond and third blades; and after this it begins to ſhoot freſh roots and branches from this ſame head, till in time it grows very large, eſpecially in a fruitful ſoil and a good ſeaſon; and it keeps on ſhooting freſh roots all the growing ſeaſon: now if the corn is too deep, and a ſevere froſt happens while this head is forming, the plant is quite deſtroyed: but if it lies ſhallow it ſhoots a new blade from the corn, and goes on in its operations as before; this was the caſe in 1763, a ſevere froſt happened in the night of the thirteenth of February, which deſtroyed a good deal of wheat; ſo that ſome which lay deepeſt was ploughed up, and ſown with other ſeed in the ſpring. Laſt year multitudes of plants were killed in the ſame manner, and brought the crop very thin. In ſhort, I am very certain, that whoever will make their obſervations will find that what I have ſaid is the truth; that the ſhalloweſt corn will flouriſh ſooner and better, and from thence will be led to ſee the advantage of drilling wheat.

But although I intend leaving Mr. Tull's method of ſowing wheat, yet I hope always to follow it in beans and turnips.

My beans I have ſown theſe four years in double rows, about ten inches a part, and about two feet intervals. Theſe I plough from and to the beans, when about ſix inches high; this is done with a little ſull drawn by one horſe, and will plough three acres in a day. This method hath ſucceeded ſo well, that many are come into it; although the farmers have always an averſion to new methods of managing; we ſow but one-third of the ſeed and have a much better crop, as is allowed by all.

As for turnips, all my neighbours will allow the drill to beat every thing. I ſow a double row about eight inches wide, on a ridge about five feet, and though I did not ſow this year till Auguſt, I have turnips two feet round, after wheat. I have given them but one ploughing as yet, beſides hoeing them out at proper diſtances. I believe all will acknowledge I have double the crop in weight with any ſown in the old way. I left four intervals unploughed in one cloſe, to ſee the difference, and it is very ſurpriſing. One of my neighbours was prevailed on to ſow a few rows in a piece he was ſowing, and let my man plough them. The difference is ſo great that he is become an advocate for the drill huſbandry; indeed I do believe that it will ſoon make its way through all the prejudices of the old farmers to the contrary; eſpecially as we have a drill invented by an ingenious carpenter, with which ſeveral farmers have ſown beans, peaſe, turnips and wheat, and it anſwers exceedingly.

For theſe ſeventeen or eighteen years paſt, I have been ſtriving to improve a crop of turnips. Before this, nothing was known or aimed at hereabouts, but ſowing in the common way, one pound of ſeed on an acre; and then come thick, come thin, weeds and all grew together, till the ſheep were turned in to eat the crop as it was, and generally it was very poor.

The firſt improvement I made was by Ellis's direction, to drag them well with heavy harrows till they were got pretty thin, by which method I ſoon got better crops than any about me But then I ſowed double the quantity of ſeed, that I might have ſufficient ſtock of plants for my after huſbandry. My neighbours were ſoon convinced of the advantage of this, and followed my example, which is now the common practice. After this, finding the thinneſt was beſt, I got ſome hoed; this I found ſtill better, but very expenſive, our people being not uſed to it. I tried Mr. Ellis's receipt to prevent the fly from deſtroying the young plants, but my ploughmen refuſed to ſow the ſeed when mixed with ſulphur. I then invented a long box, made full of holes, for the ſeed to fall through, and faſtened it to two wheels ſo as to keep it above ground; this went ſo light that a boy could draw it, and ſowed the ſeed very regularly. I ſhewed this to a friend of mine, (Mr. Joſeph Pittfield, of Sidland in Dorſet) who had one made immediately; and ſoon made an improvement on it, by having the holes made in rows about a foot aſunder. Finding that the plants could be thinned and cleared at a much leſs expence, I followed this method of ſowing for myſelf, as did ſome of my neighbours, for ſome years, and with a deal of ſatisfaction. A few years ſince, I was willing to try what ſtirring the ground deeper would do; and being reſolved to try the drill huſbandry in corn likewiſe, I had a ſmall ſull made, with which one horſe will plough more than two acres in a day, firſt turning four or five inches deep from the plants, and then back to them again: we generally ſow turnips after wheat, peaſe, and flax, and my method is to plough the ground into ſix furrow ridges, which with the open furrow makes about five feet in breadth. On ſuch a ridge I ſow (out of a ſhort box) two rows of ſeed, though ſometimes but one, and harrow it in with a very light harrow. When they have four or five leaves I get them thinned, and give them a ploughing; and ſome time after, when they begin to kern, I have them

thinned

thinned and cleaned again: and this is all the huſbandry I have hitherto beſtowed, and all I think is neceſſary, as we do not ſow till late; the coſt of which is about three ſhillings *per* acre.

I have ſown ſome betwixt rows of beans, and they anſwered very well: when the beans were pulled, I had the plants thinned and cleaned, and the earth ploughed betwixt the rows.

The firſt I ſowed laſt year was a ſmall piece about half an acre, where hemp failed: I had the ground ridged up, and ſowed with two rows of ſeed, and managed, as I ſaid before: indeed the ground was dunged for the hemp. This was ſown the latter end of July, but did not come up till the middle of Auguſt, for the want of rain. I pulled them before Chriſtmas, and had fifteen putt loads, which every one will acknowledge to be a good crop; I believe double a common one; and tho' the rows were four feet apart, the leaves touched each other. The next I ſowed was after wheat, about the middle of Auguſt: when the wheat was carried off, I had the ground ploughed into ridges where the old furrows were, and ſowed one row of ſeed on each ridge: theſe coſt but little in thinning and cleaning, and once ploughing, and were a very good crop: the largeſt of them was more than two feet round, and weighed above ſix pounds; indeed towards the hedges they were much ſmaller; I had fifteen putt loads per acre, though the ground had bore three crops ſince it was dunged. Another piece of two acres I ſowed after peas, in double rows; but not till the latter end of Auguſt: I had the ground ridged up, and when the plants were fit, I had them thinned and cleaned as uſual, but left four ridges for ploughing to ſee the difference; and truly it was ſurprizing: thoſe that were ploughed were more than three times as large, though they had all the ſame huſbandry, except ploughing. They are as good a crop as the wheat ſtubble, though ſown later, which makes me think double rows are beſt: our ſoil is moſtly heavy good ſand.

We have reſerved for this article the following account of ſeveral very important experiments made by Mr. John-Wynn Baker, under the direction of the Dublin Society, and publiſhed at their requeſt, on the culture of cabbages, the turnip-cabbage, boorcole, and turnips, by various methods; with an accurate ſtate of the produce; and of the abſolute and comparative advantages of each in feeding ſheep and horned cattle. *See the articles* BOORCOLE-CABBAGE, POTATOES, and TURNIP-CABBAGE.

In the month of March, 1763, two acres of ground, very highly manured with dung, were planted with potatoes, in the manner uſually practiſed in this kingdom, with ſpade and ſhovel; in the beginning of November following the potatoes were dug. The land being low, and the winter very wet, it could not be plowed until the beginning of March, 1764; when, it ſhould be obſerved. the under ſtratum, upon which the dung and potatoes lay, roſe at the plowing as ſtubborn and ſtrong, as if no part of the ground had been tilled before: which proves the potatoe tillage, in the manner in which it is uſually practiſed, not to be ſo beneficial to land as is generally imagined: the fact being, that only about thirty inches in every nine feet of the ground is tilled at all.

In the night of the 10th, and on the 11th and 12th, of May following, there was very fine rain; this rain enabled me, on the 12th, to reduce this ſtubborn ground pretty fine by the harrow.

In the month of March, 1763, the other part of this field was broke for fallow (an improper time to break fallows; but, my entrance upon the farm in that month was the cauſe); in June following it was croſs ploughed, which brought it into very large lumps; from the poſition this ploughing threw them into, they were expoſed, in a greater number of points, to the influence of the weather, than the ground would have been, had the ſecond ploughing been in the ſame direction as the firſt.

In this ſituation I left this fallow till the March following; when, it was ploughed for the third time, with the potatoe ground, in the ſame direction as at firſt; by this third ploughing this land was brought into an exceeding fine tilth.

This benefit aroſe from the ground not having been harrowed at all. This is ſomething contrary to the common mode of culture; but was adapted to the ſpecies of ground I had to work upon; which I ſhall deſcribe hereafter.

What the harrow would have done in part towards reducing it after the ſecond ploughing, was completely effected by the influence of the ſummer and winter; the firſt deſtroyed all the weeds and couch-graſs (with the latter of which the ground abounded); and the lumps exfoliating by the operation of the winter, by degrees fell into fine mold; whereas, had it been harrowed before the winter, the rains would have run the ſmaller particles together, ſo as to have given a great adheſion to the ground before the ſpring; abſtracted from the like miſchief, which the cattle would have done by drawing the harrow. In the beginning of June, I ploughed this part of the field a fourth time, and the potatoe ground a ſecond; by which ploughing I laid the whole field into ridges of five feet width, except about half an acre, which I reſerved for other purpoſes, as will appear hereafter.

In this field I had two parcels of manure ready prepared for it. One conſiſted of earth raiſed from the headland, mixed with lime, which lay about twelve months, having been in that time twice turned.

The other parcel conſiſted of the like earth, and lime, mixed in the ſame manner, after which I mixed dung with it, *ſtratum ſuper ſtratum*, which lay about two months, when I turned it: after which it lay about two months longer: by this ſtirring the ingredients, of which this parcel was compoſed, were perfectly incorporated with each other; and a new putrefactive fermentation was excited in it; which perfectly prepared it for the land: and all the earth was ſo fully impregnated with the juices of the dung, that it was very little, if any thing, inferior to the dung: whereas, when dung lies by itſelf, great part of the volatile ſaline particles are loſt, as ſoon as the fermentation begins: ſome fly off in vapours, and others run off with the juices of the dung and rain, which fall upon it.

When I have mixed dung and earth, in the manner already deſcribed, I always once, or twice when the ſeaſon affords it, cover the compoſt with a large quantity of ſnow, or ice; which, upon diſſolving in its paſſage through the whole, cauſeth the earth to be finely impregnated by the dung. Snow, by being gathered with ſhovels or rolled together in balls, is longer diſſolving than ice, and therefore I prefer it, unleſs it be ice of water which happens to be the ſoakage of a dung-yard, ſuch ice being always replete with food for vegetables.

The land being now, in June, in five feet ridges, in the manner already deſcribed, I began to draw out my compoſt; which I diſpoſed in the following manner: I drove the cars up every alternate ridge, and upon each of them dropped the compoſt, till I had manured about three acres of the fallow ground; then, with ſhovels, I divided this manure, as equally as could be, in every furrow; which was readily done, from the convenient manner in which it was depoſited.

In the ſame manner I put out the other parcel of manure (which, it may be remembered, I before ſaid conſiſted of lime and earth) upon an acre and a half of the potatoe ground; and on a part of the fallow ground, where no compoſt, or other manure, had been put; and ſpread it in the ſame manner as the former.

The whole field being thus manured, I ploughed it again, which was the fifth ploughing of the fallow, and third of the potatoe ground: by this ploughing I altered the poſition of every ridge, by laying the middle of each exactly over the manure; conſequently the furrows were made, where the middle of the ridges was before.

The half acre before-mentioned I manured with at leaſt double the proportion of compoſt, which was allowed to the other part of the fallow; as it was flat, and it was neceſſary to manure every part of it, being intended for turnips, to be ſown in the promiſcuous way.

To this piece of ground I gave a ſixth ploughing; as it could not have the benefit of the horſe-hoe, when cropped, and therefore I thought it neceſſary to reduce it as fine as poſſible, in order to give the broad-caſt crop of turnips every advantage I could.

The field being prepared in the manner already deſcribed, I proceeded to crop the land in the following order.

July the ſixth and ſeventh, I planted one row of cabbage plants, upon the middle of every ridge, of about an acre of the fallow ground, the plants in the rows two feet from each other. In like manner I planted about half an acre with turnip-cabbage plants.

Hence it may be obſerved, that the plants were in rows five feet aſunder, and two feet aſunder in the rows.

This buſineſs ought to have been done, at leaſt, a month ſooner; but I could not get the ground ready in due time; however, the ſucceſs of theſe crops may encourage others not to give up their expectations, although they may happen to be as late as I was, which muſt frequently happen in a courſe of buſineſs; though this is always to be avoided as much as poſſible.

I never begin to put my plants out till about ſix o'clock in an evening, unleſs I can be ready for planting in a rainy day, which is always to be preferred; in the other caſe, I always keep the men at this work as long as they can ſee. If it can be done in, or immediately after, rain, that will ſave the expence of watering the plants; which is an object worthy of attention in a large work of this kind; beſides the circumſtance of the plants ſucceeding much better.

On Friday the ſixth of July we had fine rain, and on the ſeventh I finiſhed. On the eleventh we had ſome light ſhowers, and on the twelfth fine rain, which ſecured life to my plants; but they began to look ſickly before the twelfth; three of the intervening days having been hot and dry.

On the ſeventh I alſo planted three of the five-feet ridges, with one row of boorcole plants on each ridge, the plants in the rows two feet aſunder.

Be it obſerved, that, for the obtaining large cabbages of the ſpring ſowing, the ſeed ought to be ſown early in March; and, if once planted out before the final planting them, it will be an advantage to the crop; the caſe is the ſame with reſpect to turnip-cabbage; but it is more eſſentially neceſſary in the common way of raiſing cabbages; for, otherwiſe, they will run into long ſhanks, and will not cabbage well; moſt gardeners allowing their plants too little room: this is not the caſe here; my cabbage and turnip-cabbage ſeeds were not ſown till the twenty-ſixth of March, and I was ſo much hurried, that I never had time to get them planted out before the final planting, ſave about three thouſand plants; and yet they are all very ſhort in their ſhanks. This may juſtly be attributed to the manner of diſpoſing them, and the culture they receive in this huſbandry.

Here I cannot omit to remark one circumſtance, for the obſervation of gentlemen and farmers who may adopt this huſbandry, viz. That I have not one cabbage this year of the ſort I intended to have; what I have being chiefly ſugar-loaf, the ſeedſman having deceived me; and, if I had not happened to have about an ounce of turnip-cabbage ſeed by me four years old, I ſhould not have had one plant of that kind this year; the ſeed, which I bought in Dublin for it, turning out a poor, ſmall, wretched cabbage.

I ſhall now proceed to make my report of the farther treatment and ſucceſs of theſe crops, before I proceed to the turnips, &c.

Upon the 17th of Auguſt, I horſe-hoed my cabbage, turnip-cabbage, and boorcole, for the firſt time, by taking off, at one furrow of the plough, only one ſide of each ridge, cloſe to the plants: thus they remained till the 25th, when I ran the plough in the ſame furrow; by which, with the firſt furrow, I plowed about twenty-one inches deep. This being finiſhed, I immediately returned the earth back to the plants; this afforded them freſh nouriſhment; and in order to give their roots time to penetrate this freſh earth, which, by the horſe-hoeing, was become very fine mould, I let them remain in this ſtate till the twelfth of September; when I horſe hoed them again, by taking off the other ſide of every ridge; and, on the twentieth, deepened the furrow in the ſame manner as the former, and immediately returned the mould back to the plants; and, on the eighteenth of October, threw up a ſmall furrow on each ſide of every ridge, which finiſhed the culture of theſe crops, and reſtored the ridges to the form in which they were when the plants were put out upon them.

The plants all grew very luxuriantly; and, in the hotteſt weather, were infinitely more brittle in their leaves, than any I could ſee in the gardens of my acquaintances: which is a certain indication of health in this kind of plants.

The horſe-hoeing was ſo effectually deſtructive to weeds, that it coſt me but four-pence to weed theſe crops, which occupied about an acre and three quarters of ground.

The repeated horſe-hoeings coſt me two ſhillings and four-pence an acre, for workmen's wages, excluſive of horſes, of which I uſed two, and ſometimes three.

December the 8th, I cut one row of the cabbages, they beginning to decay, which is indicated by their burſting. The number was two hundred and fifty-eight, and they weighed ſixteen hundred-weight, three-quarters, and twenty-one pounds, *i. e.* one thouſand eight hundred and ninety-

ninety-ſeven pounds: which, at an average, is ſeven pounds and near ſix ounces for each cabbage.

The produce upon an acre, on weighing this row, which was five hundred and ſixteen feet long, amounted to twenty-three tons, four hundred, two quarters and fourteen pounds, *i. e.* fifty-two thouſand and thirty-eight pounds: which is, at leaſt, from ten to ſeventeen tons leſs, as I compute, than the produce would have been upon an acre, had I obtained the ſort I intended to have, which was the large, late, Dutch cabbage. However, ſuch a produce as was here obtained, will be an ample reward for the labour any one may beſtow in his huſbandry, as will appear when I ſhall come preſently to ſhew how many cattle twenty-three tons will maintain.

December the 17th, I took up one row of the turnip-cabbages, which were in number two hundred and forty-nine, they weighed eighteen hundred weight, and fifteen pounds, *i. e.* two thouſand and thirty-one pounds, after chopping off the roots and ſtalks below the turnip, which ought not to be weighed, as being no part of the food for ſheep or cattle: the weight of theſe plants, one with another, was ſomething more than eight pounds and two ounces; ſome few weighed fourteen and fifteen pounds. The produce upon an acre, on weighing this row, which was four hundred and ninety-eight feet long, amounted, at the ſame proportion, to twenty-five tons, fifteen hundred, three quarters and ſeven pounds, *i. e.* fifty-ſeven thouſand ſeven hundred and ſixty-one pounds.

This crop was much greater than ever I had before; and, from ſome obſervations I have made this year, I am inclined to believe, their culture may be improved to a produce of ten tons more upon an acre: but, abſtracted from that, the produce already obtained is more valuable than any crop I know of, for they are invincible by the winter, either in or out of the ground. The great diſtreſs of even the careful farmer is in the months of March and April, for his ewes and lambs, when turnips are gone, or are but very indifferent food, and all other green winter-food is exhauſted.

Feeding ewes upon dry hay affords but little milk to their lambs; add to that, hay is not made without great expence and anxiety, over and above the rent of the land; for really, where the farmer is ſo unfortunate as to have his hay upon hand in wet weather, it is a buſineſs which will exerciſe his patience, no leſs than it will conſume his money.

One ſuperior excellence in theſe plants is, that ſheep will prefer them to turnips; another is, that they are a firmer and more ſubſtantial food: and, to aſcertain their firmneſs in texture, and quality in keeping after being drawn, I have kept them near twelve months expoſed to the open air, to the extremes of heat and cold, and, after that, they were ſound, ſave ſome few.

If any perſon who may cultivate this plant for ſheep, ſhould keep a large ſtock, he may let the plants remain in the ground till he wants them; in that caſe, he may turn the ſheep into the field, where they will eat them quite down to the ſtems; and, as the plants ſtand naturally above the ground, and by my manner of cultivating them, they are ſtill higher, by being placed on the tops of the ridges, the ſheep cannot dirty them, as they do turnips when turned into the crops; add to this, that when the ſheep have eaten all the leaves, and begin to eat the butts or turnips of this plant, they will not rot as turnips do, when wounded; but will certainly keep ſound, even after that, for ſix weeks or two months: nay, yeſterday, the fifteenth of February, upon dreſſing ſome of them for ſeed, I found ſome, which had been accidentally wounded by cows, upwards of three months ago, perfectly ſound, notwithſtanding the great quantity of rain which had fallen upon them.

When the leaves are wanted early in the winter for ſheep, or black cattle, or, the land is wanting for any other crop; in either caſe the plants may be taken up, the leaves taken off, and the turnips thrown any where upon a piece of ſound dry graſs ground, where they will keep, and be ready for ſheep in the ſpring: but this work is attended with ſome trouble and expence, the roots being very firm in the ground.

The latter end of December, and in January, the plants begin to throw out freſh ſhoots, which are to produce the ſeed; and, when they begin to do ſo, all the leaves of the preceding year fall off, being firſt greatly decayed; and as the leaves, in October and November, are really very numerous, and afford a large quantity of food for cattle, it is well worth the trouble to take them off before they begin to decay; and, when this is judiciouſly done, the trouble is very little.

The method which I would recommend is, that two men be ſent into the field, each taking one row before him, and, as he pulls off the leaves, laying them upon the ridge between the turnips; when theſe two ridges are finiſhed, or as many as may be thought neceſſary, let one horſe, or more, be brought with a pair of cleeves upon his back; let him be placed in the furrow, between the two rows; and, as he paſſes along, the two men fill the cleeves, which may be moſt conveniently done, from ſuch a diſpoſition of the buſineſs, without any injury to the turnips in the rows.

Where extenſive crops of theſe plants are raiſed, it will be very uſeful to collect all the roots, whether left in the field by ſheep, or otherwiſe ſeparated, and mix them with heaps of earth, where a putrefactive fermentation will ſhortly commence, by which the earth will be ſtrongly impregnated with volatile and fixed ſalts, and will then be an excellent manure; and, indeed, all ſucculent vegetables will contribute to the ſame end, under the like treatment.

I muſt beg leave in this place juſt to mention, for the conſideration of the ſociety, and which I earneſtly recommend to be tried by mariners, another uſe, to which, I think, this plant may be converted, which is ſtill of more importance, than any which I have yet named.

We loſe more men in the beginning of a war in the navy, as I have been informed by the navy-ſurgeons, by the ſcurvy, than by the enemy, which is attributed to their ſudden change of food. From freſh proviſions and vegetables on ſhore, the men are at once brought to ſalt proviſions.

The turnip of this plant, I am inclined to believe, would keep three or four months on ſhip-board, perhaps longer; but the navy-ſurgeons have told me, that if it would keep ſix weeks, it would ſave the lives of many men. Something has been ſaid on this ſubject before, in a pamphlet intitled, Hints on Huſbandry, in a letter to the Dublin ſociety, printed by Flinn, in Caſtle-ſtreet.

I cannot diſmiſs this ſubject, without earneſtly recommending the culture of this plant to the attention of the farmer, particularly to ſuch as keep any ſtock; and, although the plant is very little known, except in the gar-

dens of the curious, yet, whoever will cultivate it in the way I have here ſet forth, will find himſelf amply repaid for his labour; for how comfortable is it for a man's mind to be at eaſe about his ſtock, in the months of ſcarcity? Whereas I have every year obſerved, that the farmer's ſtock, particularly ewes and lambs, are turned into his meadows to live upon the ſpringing graſs, to the irrecoverable injury of the hay-harveſt; as frequently have I ſeen them upon young clover, to the manifeſt injury of that crop.

I could enlarge greatly upon theſe injudicious practices; but in brief I ſhall only ſay, that if I ſhall live to ſee the culture of this plant generally eſtabliſhed, I ſhall have the comfortable reward of knowing that I have been uſeful to mankind; a circumſtance which will be more grateful to me, than if I had conqured a nabob, or extirpated an Indian nation.

December the eighteenth, I cut two perches in length of one of the rows of boorcole, which contained twenty-one plants; they weighed one hundred and eighteen pounds, which is very near five pounds ten ounces for each plant: but I am inclined to believe, that theſe plants will ſucceed as well, if they are planted only eighteen inches aſunder in the rows. However, at the above proportion, there would be ſeventeen tons and fourteen hundred upon an acre. But, if the produce would be the ſame, were the plants only eighteen inches aſunder, in that caſe an acre would produce, by this culture, above twenty-three tons and twelve hundred.

This plant is well worthy the farmers or graziers attention, for, as faſt as it is cut, it will again, in about a month or ſix weeks, afford another crop: I have been cutting theſe plants for my family-uſe ever ſince the middle of Auguſt laſt; I believe ſome of them have been cut three times; and they are excellent for the table For feeding cattle and ſheep they are highly valuable, as no froſt will injure them; and, although the firſt crop amounts not to as many pounds upon any given quantity of ground as the others, yet the ſucceeding crops will, I believe, make their produce nearly, or quite, of equal weight with any other of the cabbage kind. But I muſt not omit to obſerve, that, as theſe plants afford only open leaves, and many of them very ſmall, there will be a little more trouble in collecting and carrying them to the ſheep and cattle, than there will be with the other kinds.

It may not be improper to obſerve, likewiſe, that, upon the approach of the ſpring, when they begin to throw out their ſpring-ſhoots for ſeed, if the large leaves have not been taken off for winter uſe, they will decay and fall off in the ſame manner as the turnip-cabbage leaves have already been deſcribed to do.

I have not yet tried it, but I believe that the beſt way of uſing this plant, would be to allot one whole field to the culture of it, proportioned in ſize to the ſtock intended to conſume the produce; and in September or October, to turn the ewes into the field for a few hours, morning and evening, and then lodge them on any piece of graſs or fallow, which may want improvement, to which they will greatly contribute by emptying themſelves upon it; and thus continue turning them into the boorcole field, till they have eat all the luxuriant leaves; then let the plants reſt a month, and there will be another crop. By having two ſmall fields under this crop, a flock of ſtore-ſheep might be maintained a whole winter at a very ſmall expence; for whilſt the produce of one field would be conſuming, the other would be coming on.

This method occurred to me from an accident, which attended my boorcole this year. My cows got into the field, and preſently devoured ſome of the leaves of the plants; theſe plants have engaged my attention ever ſince, and I have the pleaſure to ſee them again in a very luxuriant ſtate.

If any perſon ſhould be able to put this ſcheme in practice before I can accompliſh it, I recommend it to them, not to let the ſheep paſture ſo long upon the crop, as to wound the ſtalks for want of leaves; as too great an injury to the ſtalks may check the ſucceeding growth; which injury, I am inclined to believe, will not happen to the plants, at leaſt not in ſo great a degree, whilſt they have a ſufficient quantity of leaves.

It doubtleſs will be obſerved, that I confine this ſcheme to ewes or ſtore-ſheep: my reaſon for that is, that fat ſheep ſhould always have as much food before them, as they may chooſe to eat; add to this, that ſheep, when they are fat, are more ſubject to be lame, than ſtore-ſheep, to which ploughed ground will greatly contribute.

We ſhall now return to the ſtate of the field, in which it was after being manured, and ploughed into ſmall ridges of five feet breadth, with the compoſt under them in the fallow part, and part of the fallow with the lime and earth, and the potatoe ground aided with the lime.

Upon the fourteenth of July, I ſowed with my drill plough what remained of the ridges of the fallow manured with the compoſt. That part of the fallow which was manured with the lime and earth, and that part of the potatoe ground which was before deſcribed to be in ridges, with turnips: and that part of the fallow before deſcribed to be flat, and manured with a double proportion of the compoſt, I ſowed in the promiſcuous way with turnips alſo.

The drilled turnips filled only one row along the middle of each ridge.

When the drilled turnips were about three inches high, I thinned them by hand, as being much preferable, and more expeditious than any inſtrument, intending to have them ſingled out to about one foot aſunder in the rows: but, it being ſo new a work, the women could not be brought to do it effectually at once, they apprehending, that the whole crop would be loſt, and urging, that they were ſure there was already too much ground allowed to one row: under theſe circumſtances, I could not get this work done quite to my mind this year, as I had, beſides this field, two others ſown in the ſame way, amounting in all to about twelve acres.

My turnips ſhould have been ſown at leaſt three weeks earlier; but the immoderate, and continual rains of the preceding winter, involved me ſo much with my ſpring-ſowing, that I could not accompliſh my turnip-ſowing earlier.

The turnips, after being thinned, received the horſe-hoeings much about the ſame time, and diſtances, as the cabbages; with this difference only, that I deepened the furrows of but a few ridges in another field by a ſecond ploughing in the ſame furrow, which I did not find to benefit the turnips much: for, if the ground be well prepared before the ſowing, the depth of one furrow will be enough for turnips, provided that be deep and bold.

Thinning the turnips in drills by hand coſt me eight-pence an acre; weeding of them coſt me four-pence; and

the repeated horſe-hoeings about fourteen-pence an acre for workmen's wages, excluſive of the horſes, of which I generally uſed two, except in very hot days, and then I found three were neceſſary.

The broad-caſt turnips were carefully thinned by hand, when they were about two inches high; which the women did with more courage than they did the drills; and ſometime afterwards, I hand-hoed them once, and wed them twice.

Thinning them by hand coſt me four ſhillings. Hoeing them afterwards coſt eight ſhillings, and weeding them coſt me two ſhillings and four-pence. They were ſcarcely half an acre; this expence being therefore doubled, they coſt me at the rate of twenty-eight ſhillings and eight-pence an acre, over and above the extraordinary ploughing, and double proportion of manure.

In truth, this crop greatly exceeded my expectations, being by far the beſt I ever had in the broad-caſt way; but I attribute their ſucceſs wholly to the thinning them by hand; for two, three, four, and often more, turnips will be ſo united and interwoven, that it would be impoſſible for the moſt dextrous hoer to ſeparate them; whereas the fingers and thumb will preſerve the maſter plant, whilſt the others are moſt conveniently drawn from it by the other hand of the perſon employed: add to this, that there is no labour in which we are more liable to be deceived, than turnip-hoeing.

In one of my other turnip fields I manured about an acre of ground with ſhell marle, which I ſowed in drills with turnips in the ſame manner as the former, on the ſixteenth of July.

In the ſame field, I manured about half an acre with the native earth, which had been expoſed to the weather for upwards of two years, which I ſowed likewiſe in drills with turnips on the ſixteenth of July.

Both theſe crops were thinned by hand, and horſe-hoed, in the ſame manner as the former.

Thus we have five experiments in the drill way upon turnips, with different manure. One with the compoſt already deſcribed, one with lime, one on potatoe ground, aided with lime, one with ſhell-marle, and one with native earth; and alſo one in the broad-caſt way, with a double proportion of the compoſt, and an extraordinary ploughing.

The principal point to be determined by theſe experiments is, whether ſowing turnips in drills, or the broad-caſt way, will afford the heavieſt crop: but the trials with the different manures will, I hope, be alſo uſeful.

The produce of drilled and broad caſt turnips compared.

December the ſeventeenth, I meaſured out three ſquare perches of the beſt of the broad-caſt turnips, and alſo three ſquare perches of the drilled; and the produce was as follows:

The three perches of the broad-caſt turnips weighed ſixteen hundred weight and one quarter, *i. e.* one thouſand eight hundred and twenty pounds; which, at the ſame proportion, amounts upon an acre to forty-three tons, five hundred weight, three quarters and ſix pounds, *e. i.* ninety-ſix thouſand nine hundred and ſeventy pounds.

The three perches of drilled turnips weighed ſeventeen hundred weight, two quarters, and twenty-one pounds, *e. i.* one thouſand nine hundred and eighty-one pounds; which, at the ſame proportion, amounts upon an acre to forty-ſeven tons, two hundred, three quarters, and two pounds, *i. e.* one hundred and five thouſand five hundred and ninety pounds.

	T.	C.	Q.	lb.		Pounds
An acre of drilled turnips	47	2	3	2	or	105520
An acre of broad-caſt ditto	43	5	3	6	or	96970
In favour of the drilled	3	16	3	14		8620

Thus we ſee, that, notwithſtanding the extraordinary proportion of manure, and the extraordinary ploughing, which was afforded to the broad-caſt turnips, the drilled crop, with intervals of five feet, produced the greateſt quantity upon an acre, by three tons, ſixteen hundred, three quarters, and fourteen pounds weight.

The drilled turnips in my other fields were very large, regular, and even crops, as many gentlemen ſaw during their growth.

Thoſe ſown on the acre manured with the ſhell-marle were very near as good as the reſt—thoſe ſown on the potatoe ground were not near ſo large, but were regular—thoſe ſown on that part of the fallow-ground which was limed, were very poor crops—and thoſe ſown on the ground manured with the native earth were miſerable.

The crops in my other fields were all treated in the ſame manner as that already deſcribed; except, that the fallows were broke in September, 1763, inſtead of March, 1763.

It now remains to deſcribe the nature and quality of the land, and then to draw concluſions from the various experiments.

Tne land lies upon a lime-ſtone quarry, which is very near the ſurface; and is, naturally, a very ſtrong and ſtubborn ſoil, with an infinite number of looſe lime-ſtones in it. With dry winds, or a parching ſun, the ground unites, and is as hard as bricks; moderately wet, it is reducible by inſtruments; but, when thorough wet, it runs together, and is like brick-clay when tempered. This, I repeat it, is the natural quality of the land, and is what the writers would call a barren, grey, ſtiff earth, but is not quite a clay.

I have found repeated tillage, when the land is in a proper ſtate of moiſture, will reduce it, and diveſt it of its natural adheſion. Tillage and manure together render it capable of producing any thing; as, I believe, ſuch agents will do upon any land, provided it can be kept moderately dry. The fields, which I had under turnips and cabbages, have been in appearance all the ſummer a fine loam, and really bore the complexion of very fine land, abſtracted from the rich appearance of the crops.

I recommend to the practice of all perſons, who may have ſuch land as this to work upon, never to harrow the fallows before winter, but as early as may be in the ſpring, and during the working the fallow in the ſummer, but not to leave more than one day's ploughing unharrowed, but rather harrow in the evening what has been ploughed in the morning, and then the harrow will reduce it; but if the ploughing is continued for two days, without any harrowing, the harrow will have no more effect upon the land, than it would have upon bricks, unleſs it be moiſtened with rain; in which caſe it will be reducible, as, it may be remembered, I deſcribed the potatoe ground to have been reduced, after rain which fell on the twelfth of May.

Concluſions to be drawn from the preceding experiments.

Theſe experiments prove gardens to be no more than farms in miniature, under an extravagant expence of culture; ſince we can with the plow raiſe more tons of the larger kinds of garden vegetables for twenty ſhillings, than by the ſpade for as many pounds: and, indeed, I do not ſee, why moſt of the ſmall ones may not be raiſed in the ſame way.

They alſo prove, that it is profitable for the farmer to raiſe different ſpecies of cabbage for his cattle in winter; and I have it in contemplation to try them for ſummer uſe alſo. However, for the winter, it is an object of great importance, not only to the well feeding of cattle, but to the ſaving an infinite conſumption of hay, which by this huſbandry may, at leaſt, be paſtured in ſummer.

The experiments on the turnips prove, firſt, that it is more profitable to raiſe them in drills, than in broad-caſt: ſecondly, that the culture is a great deal cheaper: thirdly, that leſs manure will produce a larger crop, than in broad-caſt, provided it be diſpoſed in the ſame way as mine was; fourthly, practice ſhews the expence of drawing the drilled turnips for ſheep or black cattle, to be at leaſt two-thirds leſs, than drawing the broad-caſt: fifthly, in the drill way not a turnip need be left upon the ground; whereas, in the broad-caſt way, the leaving many is unavoidable, to the great annoyance of the ſucceeding crop, particularly if that ſhall be barley: and ſixthly, that the land is left, after drilled turnips, in a much higher ſtate of preparation for a ſucceeding crop, than it can poſſibly be in the broad-caſt way. To theſe advantages another may be added, which I find very material, viz. that of ſlicing them for black cattle, which is highly neceſſary, even when they are ſmall, nay more ſo, for cattle are ſometimes choaked with a ſmall turnip. A man will be near as long ſlicing a ſmall turnip as a large one, and will make no diſpatch; whereas, my men and boys now ſlice for me every evening about nine hundred weight in an hour; which is a taſk upon them after night-fall, except on Saturday nights; then they ſlice double the quantity.

As it ſeems to be a paradox to ſay a man will ſlice a large turnip as ſoon as a ſmall one, it may be proper to explain it to the reader. The man is in danger of cutting his hands when he is ſlicing a ſmall turnip; but in no ſuch danger with a large one: and, beſides that, one ſlice of a large one contains more food, than two or three whole ſmall ones.

The experiments prove, that the potatoe tillage, in the manner it is now generally prrctiſed, is not ſo beneficial an improvement of land, at leaſt not of ſtrong ground, as is generally imagined: although there is a greater conſumption of dung than in any other huſbandry.

The experiment with the lime, upon the fallow ground, proves lime to be an inſufficient manure, for the high improvement of lime-ſtone ground. There are ſo many advocates for lime as a manure, that it is adventurous to ſay any thing againſt it; but, I hope, the reader will obſerve, that I pronounce upon it, as being inſufficient, "for the high improvement of lime-ſtone ground." I have tried lime in another field of my farm, in which I ſowed wheat, and my ſucceſs was no better in that than in my turnips: and I earneſtly recommend it to every improver, who may have favourable opportunities of getting lime, that he try it upon a ſmall patch, before he launches into a large expence for it; ſuch caution may perhaps ſave him money. This advice ariſes from practice; for I imprudently burnt a large quantity of lime, at an expence of near an hundred pounds, and, I can truly ſay, I have not received in benefit as many ſhillings.

The experiment with the ſhell marle, proves that to be a very high and excellent manure; for, as it will produce turnips upon poor ground, it may be ſafely relied upon for any other crop.

The native earth proves to be perfectly inſufficient for turnips; though it certainly mends the ground a little, beſides that it adds to a ſhallow ſoil.

Accidents and diſtempers.

Turnips are ſubject to be deſtroyed by the fly. In an orchard I ſowed two acres with turnip ſeed in drills in July laſt. They were invaded by the fly; I had a conteſt with them for a fortnight, and at laſt conquered them, with a loſs of only four or five perches of my turnips, which happened where there were moſt trees. Every morning before the dew was off, I had the rows daſhed with lime, which was ſlacked every day on purpoſe. This lime adhered ſo cloſely to the leaves, when they were wet with the dew, that it defended the upper ſides from injury: then I found the flies began upon the under ſide of the leaves, which I had never ſeen them do before; however, upon this, I was obliged to have the duſt thrown very low; and, whilſt the plants were wet, a great deal adhered to them, even on the under ſides:—thus I ſaved my turnips, which were as fine a crop as any I had, ſave the four or five perches before-mentioned.

The upper ſide of the turnip leaf, in its infant ſtate, is very ſmooth, and on that part the flies always lodge, unleſs they are interrupted; in that caſe they will deſtroy the plants by wounding the under ſide, which is not ſo inviting to the inſect as the upper, it being a little rough, though not enough to protect it from them.

The greateſt inconvenience I found in this work was, that every little ſhower of rain waſhed off all the lime, and then the work was to begin again; ſometimes I repeated it three times a day: however, it will be found to anſwer well, but it requires to be done with care.

I have, by the ſame method, ſaved lucerne, which is alſo ſubject to be deſtroyed by the fly, upon its firſt coming up.

I diſcovered laſt ſeaſon three diſtinct ſpecies of the turnip fly (if I may ſo call it) one of them is black; it ſeems to hop like a flea, and reſembles it exactly. The ſecond is a ſmall degree larger, and very diſtinguiſhably has wings, upon which are two ſmall white ſpecks; and the inſect is of an oval form. The third is like a domeſtic fly, but not by a fourth part ſo large.

The turnip-cabbage is ſubject to the ruſt, or mildew. In my orchard I had ſome plants put out, at different diſtances, for experiments; they grew very well for a time, but they were all infected with the ruſt, and thoſe neareſt the trees ſuffered moſt. In my field I could find but three, which were injured by this diſtemper. This ſeems to prove, that they require an open expoſure; and therefore they better ſuit the purpoſe for which I have recommended them.

Turnips, cabbages, turnip-cabbages, and boorcole, are food for black cattle and ſheep.

A ſheep,

A ſheep, I find, will conſume about twenty pounds of turnips in twenty-four hours, provided they are allowed as many as they can eat, which ſhould always be allowed to fat ſheep; but as ſheep vary in ſize, ſo I preſume will they conſume more or leſs food.

An acre of turnips, of forty-ſeven tons to an acre, will maintain one hundred ſheep fifty-two days, allowing each ſheep twenty pounds a day. My ſheep weigh about twenty pounds a quarter.

In the month of November laſt, I gave my ſheep acceſs to ſome pea-ricks, which I had erected on purpoſe for them, of which they eat with great eagerneſs; but I find they affect them in the ſame manner as they do horſes, when given to them new; for the ſheep, I apprehend, from violent cholicks, which I conceive, the peas gave them, were ſeized with ſtrong convulſions; and in this way I loſt ſix of them, in a few days, before I conſidered what could be the cauſe: but having examined the inteſtines of every one of them, and finding no ſymptoms of any other diſeaſe, I was led to draw the above concluſion; and what ſeems to confirm my opinion is, that I have not loſt one ſince I took them from the peas. If other perſons have not met with the like accident, who have fed their ſheep with new peas, it ſhould ſeem that turnips and peas together do not agree with ſheep. However, that is a fact which I ſhall ſoon be able to determine, for I ſhall admit the ſheep to the peas again to-morrow, which will be the twentieth of February; a ſeaſon in which it is imagined we may ſafely give peas of the preceding year to horſes, and therefore, I conceive, there can be no danger in giving them to the ſheep: but, if they ſhould be affected as they were before, I think there cannot remain a doubt, that the peas and turnips diſagree in their ſtomachs. And here I ſhall leave a ſpace to add to my report hereafter.

Now, the fifteenth of March, the ſheep have been ever ſince at the peas, and I have not loſt one.

Of cabbage, and turnip-cabbage, a ſheep, of about twenty pounds a quarter, will conſume about fifteen pounds a day. An acre, at that rate, will maintain one hundred ſheep about thirty-four days. The cabbage, and turnip-cabbage, are a firmer and more ſubſtantial food than turnips.

I have fed a cow this winter upon turnips, and I have now two bullocks which are ſtall-feeding upon turnips alſo. It is computed that they weigh between four and five hundred weight each; and I find by experiment, that they each of them eat about two hundred and ſixteen pounds in twenty-four hours; which is, therefore, about half their own beef-weight; from hence we may, with reaſon, imagine a beaſt will eat every day of turnips, at ſtall-feeding, about fifty-ſix pounds for every hundred weight of beef he may contain.

One of the bullocks was put up miſerably poor from the plough, for an experiment, on the fourteenth of December: he took kindly to the turnips; and on the ſixteenth I began to give him, with his turnips, pea-flower, to the amount of eight pounds every day; and I find he is greatly improved, but he will not be beef; though I am very inclinable to think, that if he had been put up ſix weeks ſooner, in April, he would have been good beef. This experiment I ſhall repeat next year. What induced me to mention it here is, that ſome other perſons may perhaps try it next winter, and, if they ſhould, I ſhall be much obliged by their report of the effect. I am led to believe, that bullocks may be profitably fed with peas, becauſe horſes, and pigs, thrive very faſt upon them.

When the cattle are firſt put to turnips they dung but little, the turnips going off chiefly by urine, the quantity of which is really incredible; but, after ſome time, they dung more; and, from a whitiſh colour, the dung reſumes the natural colour, and is of the common firmneſs. I allow each of the cattle ſeven pounds of hay every day, and I do not find that they eat fewer turnips on that account; the reaſon, I believe, is, that the hay makes them more eager for the turnips. They refuſe water.

To each of my cows, and ſtore-cattle, I allow ſeventy-two pounds of turnips a day, and a little ſtraw, thirty-ſix pounds being what I find a moderate-ſized beaſt will eat at a meal. To my plough bullocks I allow the ſame quantity of turnips, with as much ſtraw as they can eat; but I forbid them having the turnips till they have been unyoked about an hour, and after they have eat ſome ſtraw; as I conceive the turnips are too cold for them immediately after their labour.

I have lately confined a milch cow four days, and fed her with turnips, and I could find no diſagreeable flavour in her milk from that food, though I have often heard turnips complained of as giving a bad taſte to the milk, when cows are fed with them. Query, whether it might not ariſe from the leaves of trees falling upon the turnips? Leaves of trees always ſpoil the milk when cows eat them.—Here follow

Calculations upon the feeding black cattle with turnips and cabbages.

Suppoſe four cows or bullocks, of four hundred weight each to be ſtall-fed upon turnips, allowing each beaſt two hundred and ſixteen pounds a day, an acre of forty-ſeven tons would maintain them one hundred and twenty-one days. Indeed a larger ſtock ſhould be put up, or heavier cattle, as the turnips will not keep ſo long.

Suppoſe ten dairy cows to be maintained upon turnips, allowing each cow ſeventy-two pounds of turnips a day; at this rate, an acre of forty-ſeven tons will keep them one hundred and forty-ſeven days. All cattle, fed in this manner, ſhould have about ſeven pounds of hay a day allowed to each.

The fat cattle eat about one hundred and a half of cabbages a day; therefore an acre of twenty-three tons will, at that rate, maintain four bullocks, of four hundred weight each, ſeventy-ſix days.

When fed with cabbages, they dung more, and make leſs urine, than when they are fed with turnips, and will drink a little water.

Hence I am induced to believe, that cabbages are a better food for cattle than turnips. I am fully perſuaded near as many tons may be raiſed upon an acre, with proper ſeed and good management; but they will coſt five or ſix ſhillings an acre more.

There remains one general obſervation to be made, and which I imagine contributed greatly to the ſucceſs of the abovementioned crops, viz. that we had for theſe ſpecies of crops, very ſeaſonable and fine rains. From the ſixth of July, on which day I began to put down my cabbage-plants, to the firſt of December, both incluſive, we had ſeventy days, in which there was, more or leſs, rain; and the latter end of Auguſt, and beginning of September,

the heavieſt dews that I have ſeen. From the ſixth of July to December the firſt, both incluſive, were one hundred and ſeventy-ſeven days; ſo that we had but one hundred and ſeven dry days, many of which, I ſee by my kalendar, were cloudy and inclinable to rain.

"Land, ſays an Eſſex farmer, cannot be brought into too good tilth for ſowing turnips: they require a deep, looſe, well-wrought mould; and to effect this, diſcreet plowing and harrowing is the beſt way. I ſay diſcreet, becauſe one plowing, properly timed, is worth three that are out of time. It is a maxim in huſbandry, that ſome land cannot be plowed too much; but we ſhould add, at proper ſeaſons and intervals, or an ignorant farmer might ruin himſelf, and yet think he had followed the directions that were given him.

"A light land requires leſs plowing, as well as leſs nicety in the times of plowing, than a ſtiff heavy ſoil; and it is alſo ſooner brought into good tilth: two well-timed plowings will often do it; whereas a clayey ſoil will require three or four, before it is brought into order.

"An early plowing will greatly forward the getting a ſtiff ſoil into order: the month of April ſhould be the lateſt that ſuch, when intended for turnips, ſhould be turned up. It may then lie till the beginning of June, when it ſhould be harrowed down with loaded harrows to break the clods, and immediately croſs-plowed: about a fortnight after this it ſhould be plowed for the laſt time, and immediately croſs-harrowed and ſown out of hand with turnip-ſeed pretty thick, and ſcratched with a light harrow to cover the ſeed.

"Light lands, as I ſaid before, may do very well with two plowings, one in the ſpring, and the other juſt before ſowing at Midſummer.

"I look upon it that turnip-ſeed cannot well be ſown too thick, for it ſeldom all comes up, and of what does get above ground, much is often deſtroyed by the fly, and ſlug; ſo that the plants ſometimes, though the ſeed was ſowed thick, require but little thinning by the hoe. In fact, I think it better at firſt to beſtow an additional quantity of ſeed, than to have to ſow three or four times over, as I have been often obliged to do, till I practiſed this method of ſowing thick, which generally ſucceeds very well with me.

"The beginning of July is the time in which I, for the moſt part, ſow my turnip-ſeed; in this matter the grand affair is to hit it off, ſo that the turnips do not grow ſticky or ſpongy before the winter, and yet are forward enough in their growth to reſiſt the froſts, &c. and be fit food for the cattle in the winter, or in the ſpring

"To have a good and profitable crop of turnips, it is abſolutely neceſſary they ſhould, at proper times, be hoed, not only to kill the weeds, but alſo to thin the plants, and ſet them out at a proper diſtance.

"The proper time for the firſt hoeing, is when they have put forth their fourth leaf, and the ſecond hoeing ſhould be in about three weeks afterwards: twice is, in general, enough, unleſs a very following rainy ſeaſon ſhould come on, when it will be proper to take the advantage of the firſt ſun-ſhine weather, to give them a third hoeing; this, indeed, is often neglected, but I always found it pay well, by the thriving condition it put my crop in.

"As to the diſtance at which the plants ſhould ſtand one from the other, that muſt be regulated by the ſize of the turnip; but it ſhould never be leſs than one foot, nor is there occaſion for its being more than two: about ſixteen or eighteen inches is proper diſtance for the common turnip we generally ſow about me.

"If the ſoil on which the turnips grow, is light and dry, the moſt profitable way is to feed your ſheep on them in the ſpot where they grew; but if the ſoil is heavy and ſtiff, it is beſt to have them pulled, and carried in tumbrils on to ſome dry paſture, or on any dry field you want to mend; for was you to feed them on the land, one half of them, at leaſt, would be rolled in the dirt, trodden under foot, and ſpoiled.

"Land cannot be too rich, or too well dunged, for bearing turnips; and this will bring them forward, and make them eſcape the fly better; for when once the leaves become rough, the fly does not chuſe to touch them: it is therefore certainly beſt to encourage them in their growth, and bring them as ſoon as poſſible out of danger.

"When my young crop of turnips have come up, and I have been fearful of the fly, I have frequently ſown over them wood aſhes, and ſometimes ſoot: theſe have been of great ſervice, eſpecially if gentle rains followed, as neither the flies nor ſlugs choſe afterwards to touch them. But I muſt obſerve, that this is no ſafe remedy, if the weather is dry and hot, for aſhes being of a hot nature, will then be apt to burn up the crop.

"As to the ſlugs, the beſt way of deſtroying them in dry weather is with a light roller: this cruſhes and kills them, and does the crop ſervice, eſpecially if it is light land; for it preſſes the particles cloſer, ſo that the moiſture in the earth is not ſo ſoon exhaled by the heat of the ſun; conſequently, the young turnips do not ſo ſoon ſuffer by a continued drought.

"It is ſcarcely neceſſary to obſerve, that dry weather is beſt for hoeing turnips in, as then neither the weeds nor the turnips that are cut up are apt to grow again.

"In light gravelly or ſandy ſoils, the ſeed of turnips may be deeper covered than in ſtiff clayey land: in the firſt it may be pretty well harrowed in; in the latter, it ſhould only be ſlightly ſcratched with a very light ſhort-tined harrow, or even only buſh-harrowed; as by that means they will ſooner appear above-ground, be ſooner out of danger, and thrive better afterwards, the apple of the root growing almoſt entirely out of the ground, the whole nouriſhment being collected by the tap-root, and by the horizontal roots, which iſſue from it on all ſides.

"The quantity of ſeed to be ſown on an acre, ſhould be from two to three pounds, according to its goodneſs; and many uſe equal quantities of old and new ſeed, thinking this method beſt; for the new ſeed comes up firſt, and if the fly takes it, the old ſeed in a day or two ſucceeds, and generally fares better.

"If a crop of turnips fails, either through any defect in the ſeed, or by the ravages of the fly or ſlug, it is uſual for the farmer to ſow the ſame land again; and this, if there is occaſion, he repeats two or three times, till at laſt he ſecures himſelf a crop. For the reaſon above-mentioned, it is eſteemed beſt to ſow early, as by that means there will be time, if the firſt crop fails, to ſow another.

"Turnip-ſeed is very apt to take damage from wet, if it is not covered as ſoon as ſown: without this precaution it will ſprout prematurely, malt, or mould: by too early a germination the ſeed is apt to burſt.

" When peas are ſown on a rich mellow earth, they are apt to grow rank: in this manner they cover the ground, keep the moiſture in it, raiſe a kind of fermentation in the ſoil, and make it hollow and porous; inſomuch that when the crop has been off, turnips have been harrowed in without plowing, and have thriven amain: but there is danger in purſuing this practice without great caution." *Muſeum Ruſticum, vol.* I. *page* 205.

" I have, in my time, ſays a Norfolk farmer, ſown a great deal of land in turnips, and have applied them with great advantage to various uſes; but our chief reaſon for cultivating them in this county is for feeding and fattening ſheep.

" It is almoſt needleſs to ſay, that they anſwer this purpoſe extremely well, their uſe is too well known to all the eaſtern farmers, to be in theſe days controverted.

" We have various methods of ſpending them: ſome fold their ſheep on the land where the turnips grew; I have done this, but it is not a method I approve of: however, for the benefit of ſuch farmers as chuſe to practiſe it, I ſhall give one caution; which is, that they uſe wicker hurdles for folding their ſheep, which will otherwiſe be apt to thruſt their heads through the bars, and, entangling themſelves, are by that means often killed in the night, to the great loſs of the owner.

" If, however, it ſhould not be convenient to the farmer to get theſe wicker hurdles, but he ſhould be obliged to take up with thoſe made of reft ſtuff in form of a gate, let him then be careful, when he has ſet his hurdles, and ſtaked and bound them right, to pull up all the turnips that grow within two or three feet of the outſide of the fold, and throw them over the hurdles for the ſheep to eat within-ſide.

" This will take away any temptation the ſheep may have to put their heads through the bars, and they will, by that means, eſcape the danger of being ſtrangled.

" Every animal is fond of liberty; and though the ſheep will bear confinement, perhaps, better than any other creature, yet whoever has ſeen them when firſt driven into the fold, muſt have obſerved that they naturally go round the hurdles to try to find an opening to get out at: by this means the turnips which grow near the hurdles are trampled on, dirtied, and ſpoiled. For this there is a very eaſy remedy; let the ſhepherd only pull up all the turnips that grow near the inſide of the hurdles, and all will be well.

" I obſerved before, that I am not fond of giving my ſheep turnips as they grow: I think it much the better way to have them pulled; by this means they have an opportunity of eating the whole root, and my ſtock of winter fodder goes much farther; whereas, when they feed on the turnips as they grow, they generally ſcoop them out, and leave a hollow ſhell in the ground, which, though it may afterwards be forked up, the ſheep will ſcarcely even by hunger be induced to touch, as it cannot but be ſoked by the dung, urine, and dirt, from the feet of the ſheep.

" I find it then the beſt way, to have my turnips pulled before they are given to my ſheep; they go much farther, and do them more good.

" But in this method there is one ſeeming inconvenience, which is, that in froſty weather, when the ground is hard, I cannot have them pulled; yet this difficulty is very eaſily removed, by laying up, at the beginning of the winter, a ſufficient ſtore of turnips, ſecured from the wet, and not much expoſed to froſt.

" I think it worth while to have a building particularly dedicated to this uſe, and find it anſwer well: it is built in form of a ſmall barn, and boarded round.

" In the beginning of the winter, before the froſt ſets in, I have a large quantity of turnips pulled, and the dirt is carefully ſcraped off them; and, after cutting off the heads and tap-roots, I cauſe them to be regularly laid in my ſtore, with this caution, however, that all round the ſides next the boarding, my men lay ſtraw, to keep out the froſt. The heads, or tops, I give to all my cattle in general, as they are cut off; by which means I, in fact, ſuffer no loſs.

" I find theſe ſtored turnips a happy reſource when hard weather comes on; then I open my repoſitory, and deal them out to my ſheep in ſuch a manner that there may be no waſte; and as ſoon as the weather breaks, and the earth becomes leſs hard, I reſort again to the filds, and have them pulled as uſual.

" For ſome years I had another manner of ſtoring my turnips, which was by digging a deep pit in a ſandy, dry field, which being filled with turnips, they kept there very well; yet, as this method was ſubject to many inconveniences, I left it off.

" I have diſcovered another uſe for the turnip, beſides feeding my ſheep, oxen, and cows with it, which I muſt mention before I conclude this letter. I find it agrees remarkably well with hogs, which will eat of it greedily, and thrive on it apace.

" I have ſeveral times tried this, and have often killed fine young porkers that had for many weeks eat nothing but turnips boiled in ſwill, or waſh, till they were tender.

" I have at other times given turnips to large hogs, that have been put up to fatten, in order to their being killed and ſalted for family uſe; and here I was not diſappointed in my hopes; they always came on well: but I made it a cuſtom to give them, for a week or two before they were killed, a few buſhels of boiled peas, in order to harden their fat, that it might not boil away in the pot.

" I gave them boiled peas rather than raw, becauſe, having been long uſed to eating the ſoft turnip, I found they did not afterwards take kindly to the hard, raw pea.

" Hogs may eaſily be brought to eat raw, unboiled turnips; but it is much better to boil them when the hogs are to be fattened; for, though they will eat enough of them raw to keep them in tolerable good plight, yet they will not eat enough to fatten them apace." *Muſeum Ruſticum, vol.* I. *page* 335.

" I had laſt winter, ſays an ingenious clergyman of Northampton, a piece of turnips intended for feeding ſheep; but my method of conſuming them at firſt aſtoniſhed my neighbours.

" I fed them off by the fold; but I firſt turned in ſome ewes, which greedily devoured all the tops and leaves: when they had finiſhed them, I immediately folded my ewes on a freſh ſpot.

" After the leaves were eat off the firſt ſpot encloſed by the hurdles, by the ewes, I turned in ſome weathers, which eat with a very good appetite the apples of the roots, leaving, however, the lower part ſcooped out in the ground: theſe I had forked up, and they were eat by my ſtore ſheep.

"My neighbours were convinced my method was right, becauſe I evidently kept and fattened more ſheep on the ſame quantity of land, than they did; yet they begged I would give them my reaſons for this my practice.

"I told them I would readily comply with their requeſt, and the more ſo as it might be a means of tempting them to imitate what they ſaw practiſed with ſucceſs.

"Continuing my diſcourſe, I informed them that many years experience, and conſtant obſervation, had convinced me, that if you turn a parcel of ſheep promiſcuouſly into a field of turnips, the ewes and lambs would immediately attack the leaves; the fattening weathers would, for the moſt part, prefer the apple of the root; and the ſtore-ſheep, not being nice, would indiſcriminately devour both leaf and apple, and even eat the leavings of either of the others.

"I farther informed them, that I had frequently obſerved, that when a parcel of weathers have been turned into a piece of turnips, the farmer, thinking to have no waſte, generally kept them in till they have eat the roots clean up. But this is very bad huſbandry; for after the wethers have eat the moſt delicious and ſweet part of the root, they loathe the reſt, which is generally gritty, dirty, and ſodden, inſomuch that nothing, but abſolute hunger, will tempt them to taſte it. In this period they pine, and loſe fleſh; and by the time they are turned into a freſh bite of turnips, they are but little better than they were at firſt.

"The appetite of a beaſt that is fattening ſhould be tempted, not palled; and undoubtedly, ſuch of the ſheep as are moſt forward will be moſt delicate; and this delicacy, if the farmer is wiſe, he will indulge, as it will eventually turn out to his advantage.

"Thus, in my manner of feeding turnips, the ewes come firſt, becauſe they prefer the leaves; the weathers that are to be fattened follow, and make the moſt pure and ſweet repaſt; and the ſtore-ſheep, which are the leaſt nice of any, come laſt, and clear off the remains; at leaſt, as much of them as they ought to be permitted to eat; for I do not hold it good to oblige them to eat what are in a half putrefied condition, and ſodden with dung and ſtale.

"My neighbours were ſo well pleaſed with my reaſons, and ſo well convinced by what they ſaw, that they are determined to adopt my practice; and if any of your readers ſhould be of the ſame mind, it would give me great pleaſure, as I cannot feel a truer joy than what reſults from my endeavours to be of ſervice to my fellow creatures." *Muſeum Ruſticum, vol.* II. *page* 231.

"I laſt year ſowed ſome turnips, ſays a farmer near Chelmsford, on near ten acres of good light land. Some other buſineſs interfering, prevented my getting them hoed in due time, inſomuch that, by the latter end of Auguſt, they ſeemed to be almoſt covered with weeds.

"Being willing to endeavour at recovering my crop, I cauſed the field to be harrowed and croſs-harrowed, which ſet them out pretty well, and cleared away a great number of the weeds, inſomuch that the turnips got ahead, and grew to be a tolerable crop.

"I ſend you this for the information of ſome farmers, who, when they have delayed hoeing their turnips for a few weeks, if the weeds get forward, think they have loſt their crop; whereas, would they adopt this method, which has been more than once recommended, they would find it anſwer any reaſonable expectation they could form. I have ſeveral times tried it, and it always ſucceeded with me more or leſs. The work coſts but little, and the benefit reſulting from it is conſiderable. I have known farmers plough up a crop of turnips which, by harrowing, would have yielded them a good return." *Muſeum Ruſticum, vol,* V. *page* 239.

"I have known many, ſays farmer White of Suffolk, who intend feeding off their turnips with ſheep, keep the turnips till they are too old to be applied with advantage to that uſe. Your readers may give me credit, for I ſpeak from experience; and I can aſſure them, that one acre of young turnips is of more value for fattening ſheep than two acres of old ones, as the wethers you turn in will get fleſh and fat at leaſt as faſt again on the firſt as the laſt.

"Let this maxim be treaſured up in the farmer's memory; and let him not at any rate be tempted, for the ſake of ſpending a few weeds and graſs on his fallows, to keep his turnips till they are of little worth.

"If any of your readers ſhould be incredulous, let them try the experiment; it will be but little expence, and ſtill leſs trouble. I did ſo myſelf before I adopted the practice, and was in a very ſhort time convinced: this happened ſome years ago, and I have continued this method ever ſince." *Muſeum Ruſticum, vol.* II. *page* 279.

We ſhall conclude this article with the following letter we were favoured with from Mr. Matthew Cox, of Wallhampton, near Limington, in Hampſhire,

"I have, ſays he, incloſed you a draught of a hoe-plough, which I have found to anſwer very well for hoeing carrots and turnips, which may probably be improved by ſome of your ſociety: the followning is the particulars of its ſucceſs this year 1766. I took poſſeſſion of the farm I live on in April, and going ſoon after to London, ordered my ſervant to ſow two acres of carrots with four pounds of ſeed; on my return, I found he had ſown all the ſeed I had left him, being twenty-eight pounds. In May the carrots came up as thick as ſand on the ſhore. The people here being intirely unacquainted with the method of hoeing, made my work very tedious, as I was obliged conſtantly to attend them, it coſt me ſixteen and ſix-pence per acre, and the work not half done; I then harrowed them, &c. according to Mr. Billing's directions, and in June found ten times too many to come to any ſize; but could not get the ſecond hoeing performed under one guinea per acre: I then gave directions for this hoe, which I fixed to the common horſe-hoe plough, and hoed my two acres in five hours with eaſe; next day I harrowed them with common harrows. About ten days after I harrowed them again, and have kept nine horſes on them ever ſince Auguſt, except a quarter of oats in ſeed time.

Whoever uſes this plough will find it anſwer the firſt hoeing extremely well, as it will leave whatever it hopes in two inches and a half diſtant; conſequently the ſecond hoeing, which muſt be by hand, will be very triffling; and often there will be no occaſion for it. I firſt hoe the long way of the land, and then croſs it. The hoe I have is bare two inches; but I find it is too narrow.

a a, Plate XXVI. Fig. 5. are the two out-ſides of the hoe, which are flat, and ſo go on the out-ſide of the block on the common horſe-hoe at A A, Fig. 4.

b, Goes on a mortice at the bottom of the block, at *b*.

c, The pin goes through the holes on the flat ſides of the hoe at *a a* and the block A A.

d, d, d, The cutting parts two inches and a half wide; and leaves a ſpace of two inches and a half:

E, A chain that hooks to a ſtaple on the beam, and keeps all ſteady. I have ploughed ten inches deep with this hoe.

F, F, Two bars of iron worked in to the three uprights.

I always uſe the harrow belonging to the common horſe-hoe with the above. I ſometimes fix M. De Villier's cultivator to the above carriage. I have a field of twenty-two acres of wheat, in which is ſixteen different ways of ſowing, preparing the ſeed, and manuring the land.

TURNIP-CABBAGE, the name of a ſpecies of cabbage, ſo called becauſe the ſtalk, at ſome diſtance from the ground, after riſing of the uſual thickneſs, and in the manner of thoſe other cabbages, enlarges ſuddenly to ſuch a degree, that it forms a knob of a very large turnip; of which likewiſe it has ſometimes the figure, though it is, in general, more oblong.

By this peculiar formation of the ſtalk, or production of the turnip-like knob, together with its being perennial, this ſpecies of cabbage is diſtinguiſhed from all others. From the top of this turnip riſe a number of leaves, of a greeniſh-red, or ſometimes greeniſh-purple colour; which anſwer to the radical leaves in other plants. They do not, though this plant is truly of the cabbage kind, ever cloſe together, and form a compact globular or oblong maſs, as in the common ſpecies; but keep their erect growth, or turn outwards.

From among theſe leaves ſpring a number of other ſtalks, of which thoſe that are nearer the extremity, branch, and ſend out flower ſtalks, ſpreading horizontally; and thoſe that are more in the center, grow erect, and without branches. On theſe ſtalks are leaves, ſpringing out alternately, and of the ſame colour with the others. The flowers are ſmall and yellow, and ſucceeded by long cods, full of ſeed, of the ſize of that of muſtard, and a light-brown colour. We have given a figure of this plant on Plate XXVI. Fig. 6.

It may be juſtly doubted, whether or no this plant be originally a native of our country; though it is at preſent found growing wild in ſome places near Dover. But, from its general character, which does not agree with the indigenous plants of the ſame kind; from its being unknown to the earlier botanic writers, or, at moſt, known only in the view of an exotic; and from its being now to be met with wild, only in the one place mentioned, it is moſt probable, that what is there found was the produce of ſeed conveyed originally thither by ſome accident; and which has ſince propagated itſelf, and ſpread ſpontaneouſly, as it eaſily might, from its perennial nature and extreme hardineſs. It is frequently cultivated in gardens, where there are collections of vegetables: but, for the moſt part, rather as a curious than an eſculent plant. Though certainly, the turnip, or knob, is at leaſt as wholeſome as either any turnip or cabbage, and is much liked by ſome; and the leaves are alſo thought good by others; but, in general, both are ſaid to be ſtrong, and ſeldom admitted to the table with us. This plant, however, affords ſprouts, which, after they have undergone the action of a ſtrong froſt, are exceeding good; and may conſequently be had at that time when all others fail. The lying in very ſmall room, proportionably to the quantity of ſolid ſubſtance, and the keeping good much longer than any other ſort of vegetable of a ſimilar nature, are qualities, moreover, which fit this plant in a moſt peculiar manner for the uſe of ſeamen, as is ingeniouſly remarked by Mr. Baker, in his report to the Dublin Society. *See the article* TURNIP.

It appears from Gerard, that there were, in his time, two kinds of this plant; one of which he calls *caulorapum rotundum* or round rape-cole; and the other *caulorapum longum*, or long rape-cole. The difference of theſe two kinds conſiſted only in the form of the knob or turnip, as is expreſſed by the names themſelves; and in the long kind's ſhooting forth ſmooth indented leaves from the turnip part, which leaves the round kind wanted. I have here ſent you a ſketch of theſe two kinds, according to the prints Gerard has exhibited of them; and they may ſerve alſo to give ſome idea of the general figure of the plant, to thoſe who have never met with it.

I have not however ſeen in any garden, nor find any traces in the late writers, of more than one kind of this plant; ſo that if the round and long kinds, mentioned in this manner by Gerard, were really different ſpecies, the long is now loſt. But it ſeems more probable, that this was only a degeneracy of the plant, by means of the farina of the common kinds of cabbage; as the deviation from the round knob towards the plain ſtalk, and the breaking out of the leaves from it ſeem to indicate.

If there really were two original kinds, or this difference aroſe from a permanent ſeminal variation, it would merit attention under the preſent circumſtances to recover them; ſince it frequently happens in correſpondent caſes, that where there are two allied ſpecies, the one has qualities which fits it to a particular purpoſe in a very ſuperior degree to the other. This plant was rare in Gerard's time in our country; as he mentions his having the ſeed from Spain: and indeed it was ſo little known, that he ſays it is to be ſown and ſet as cucumbers and melons; and that it was then accounted a dainty meat. It did not however make its way to the table in common, or even as a curioſity in gardens, much more at that time than ſince. For Parkinſon, who wrote after Gerard, and enumerates many more ſpecies of cabbage than his predeceſſor, does not take the leaſt notice of it. Tournefort, and moſt of the later writers, mention this plant under various names; but they do little more with regard to it, than give the name and deſcription. Miller, in his Gardener's Dictionary, ſays, this kind of cabbage "never varies, for I have cultivated it many years, and have not found it to alter. It grows naturally on the ſea-ſide, near Dover. It hath a perennial branching ſtalk, in which it differs from all other ſpecies. I have cultivated it theſe three or four years, and have eaten the young ſhoots, after they have been much frozen, when they were very ſweet and good; but at other times they are very ſtrong and ſtringy. In very ſevere winters, where the other ſorts are deſtroyed, this is a very neceſſary plant, for the moſt ſevere froſts do not injure it."

Till lately we ſee, therefore, this plant was only conſidered, either as a kind of curioſity in botanic, or other gardens, where there were collections of different kinds of plants, or as an eſculent herb: but, in this latter view, it ſeems not to have acquired any great reputation, as it is ſo ſeldom, even notwithſtanding Miller's recommendation, met with on the table here; though I am well informed, that in ſome of the factories in the Eaſt-Indies, it has been cultivated from European ſeed, and is much liked.

The firſt public notice I find taken of this plant, in the preſent view of cultivating it for feeding cattle, is in a pamphlet publiſhed by the late Mr. North, gardener, near Lambeth, who ſpeaks of it, under the article of cabbage; of which he ſays, "There are four ſpecies that may be cultivated to great advantage for cattle; to wit, the white cabbage, the hardy curled Savoy cabbage, the turnip cabbage, and the green curled cabbage." When he comes to treat particularly of the turnip-cabbage, he thus expreſſes himſelf: "The turnip-cabbage is one of the hardieſt roots that grow; and I dare affirm, might be propagated to great advantage for feeding ſheep, &c. For in the moſt ſevere winter that I can remember, when cabbages, ſavoys, turnips, &c. have all been demoliſhed by the extremity of the weather, the turnip-cabbages have not been hurt. The turnip part grows all above ground, which is crowned with many large ſmooth leaves, like thoſe of the red cabbage, but which grow open like the tops of turnips. They are a very ſolid juicy root, and do not grow ſpongy when they are old, as turnips do. The tops may be cut off, and given to ſheep, &c. in the ſpring, and the roots laid by in an out-houſe to feed them in April and May, when no other roots can be had. Sheep are ſo fond of theſe roots, that they will leave the beſt turnips for them. When they are given to ſheep, they ſhould be cut to pieces; but they will eat them faſt enough, tops and bottoms, as they are growing in the fields. After Michaelmas, when turnip-cabbages have their full growth, they will weigh from four to eight pounds a root."

It may be proper here to caution againſt a miſconception, from the inaccurary of an expreſſion of Mr. North's, in calling the turnip-like part of this plant, a root; for it is no more than an enlargement of the ſtalk in that part; being, when the plants are large, ſeveral inches above the ground. It is proper to obſerve likewiſe, that Mr. North has under-rated the weight of theſe plants; it appearing, by Mr. Baker's account, that ſome weigh fourteen or fifteen pounds. This is the firſt notice I find in any publiſhed work, of this plant's being conſidered as proper for feeding cattle: but it appears in the minutes of the ſociety's books, that ſome little time before the publication of this pamphlet, on the enquiry ſet on foot by the late Mr. Wych, concerning a proper food for cattle in hard winters, this plant, together with the Chineſe or white vetch, and the Syberian medicago, were propoſed to the Committee of Agriculture for their conſideration, by a gentleman well known to that ſociety; and this plant was particularly recommended for its hardineſs in the ground, its quality of not rotting, though long kept, its nutritive property, and the fondneſs which cattle ſhew for it, when offered to them as food.

Mr. Barker, nevertheleſs, whoſe report on this ſubject to the Dublin ſociety, the reader will find under the article TURNIP, muſt have the honour of being the firſt who really introduced this plant into uſe, as an article of huſbandry. For it was on the authority of his judicious experiments, related in that report, the ſame gentleman, who formerly recommended the turnip-cabbage, as above-mentioned, to the London Society, induced them laſt year to offer a premium for its culture: and there is no one object of a ſimilar nature, hitherto taken into conſideration, either by this ſociety, or that of Dublin, which bids fairer for being of great public utility: as this plant ſeems to anſwer all the ends of what was ſought for, with ſo much pains and attention, in the reſearch ſet on foot by Mr. Wych, after a proper winte pabulum (as it was called by him) for cattle in ſcarc winters.

The turnip-cabbage may be cultivated in the manner of other cabbages; of which the particulars may be ſeen under the article CABBAGE. But the ſucceſs Mr. Baker had with his method, particularly in relation to the magnitude of the turnip, which ſeems to go far beyond Mr. North's notion, recommends ſtrongly the trial of that manner; except that, as he properly remarks, where the plants are raiſed in the ſpring, the ſeed ſhould be ſown in the very beginning of March; the plantlings, tranſplanted to a proper cloſe bed, as ſoon as they are ſufficiently ſtrong to bear it; and the final tranſplantation of them out into the field at the diſtances in which they are to grow, ſhould not be deferred later than the beginning of June. This would both give more time for the plants to become large before winter, and a better chance to avoid a total want of rain, after tranſplanting; the only accident, except the deſtruction by caterpillars, or other inſects, to which this kind of crop is ſubject; as the plants bid defiance, after they have firmly taken root, to all inclemencies of weather, either with reſpect to cold, wet, or drought.

It may be inferred from the above particulars, which, as we ſee, ſtand on unqueſtionable authority, that, conſidered as an article of huſbandry, this plant muſt be a very valuable acquiſition; as it is of eaſy culture, and as little ſubject to fail by accidents, as any crop whatever: as the produce, with reſpect to quantity, is likely to prove, under favourable circumſtances, thirty-five or thirty-ſix tons per acre, as appears from Mr. Baker's account: as its produce is greatly preferable either to turnips or other cabbages; being much more nutritious, and leſs watery and cold; a fault in the common turnips: as it may be depended on in the moſt rigorous and ſevere ſeaſon, when every thing elſe but dry fodder fails, and may be taken from the place of growth, in caſe of exigence, whenever the ground is not covered with a very deep ſnow: and as it is much liked by neat cattle, ſheep, deer, and hogs; agrees perfectly well with all of them; and fattens them in the moſt profitable manner. This is certainly very ſufficient ground of recommendation, as an object of premium, to the London Society; and it is hoped, will be ſo, as a ſubject of experiment and trial to thoſe gentlemen, or more liberal kind of farmers, who attempt improvements in huſbandry.

I have thus endeavoured to give all the light I can into the nature of this plant, conſidered as an article of huſbandry: but before I conclude, I muſt beg leave to ſubjoin a few words reſpecting it in another view, of ſuch importance to a particular ſet of men, whoſe health and ſafety manifold reaſons recommend to the care of the public, as makes it merit a very ſerious conſideration. What I allude to is, the intimation given by Mr. Baker, of the probability that this plant might be rendered extremely ſerviceable to ſeamen in long voyages. As there can be no doubt of the juſt foundation of this opinion, it ought to be kept in ſight as much as poſſible, till the matter be realized in practice. The putrid ſcurvy, ariſing from the eating ſalt proviſions, is the great bane of a ſea-faring life. The numbers diſabled or carried off by it, particularly in time of war, are almoſt incredible; and, if we conſider the public value of lives ſo loſt, both with reſpect to the national power and expence, policy, as well as humanity, bids us liſten to every

every feaſible propoſal for mitigating this evil. The uſe of vegetables in the diet along with the ſalt-beef or pork, is well known to be one of the moſt effectual means of prevention of this diſeaſe: and indeed, it has been ſo well underſtood, that great quantities of cabbages, &c. have been ſent off to the fleets cruiſing in the bay, or elſewhere within reach, to the great relief and refreſhment of the men. But this ſpecies of cabbage, abounding more in the ſaccharine juice than the other kinds, would be a more efficacious preventative or palliative of the ſcurvy; and the ſolid compact texture of theſe turnips, which makes a conſiderable weight, lye in a ſmall compaſs, together with their repugnance to that putrefaction, to which other turnips, cabbages, &c. are quickly diſpoſed, renders it practicable to keep them on ſhipboard, in any climate, for many months; provided they be preſerved from the acceſs of any extraordinary degree of moiſture.

If this plant ſhould be, therefore, generally cultivated the field-way, and conſequently produced at a very cheap rate, as Mr. Baker has ſhewn, that betwixt thirty and forty tons may be obtained by an eaſy method of culture, in one year, from one acre of ground, they might be purchaſed at a much cheaper rate than any other article of proviſion at preſent in uſe for the victualling ſhips.

This ſeems to be an object very well worth the conſideration of the India company; as it might be a means of preventing that delay and ill ſucceſs of ſome voyages, which ariſe from the ſickneſs of the men; and it is attended with no difficulty, but what regards the ſtowage. For the plant being already cultivated in ſome of the factories in the Eaſt-Indies, where it ſucceeds as well as here, and conſequently might in all the others, as no climate or ſeaſon appears injurious to its growth, it might be procured at a proportionably cheap rate, as well for the ſupply of the homeward as outward bound ſhips: and indeed, conſidering the nature and ſtate of the proviſions on board ſhips returning from India, it would undoubtedly be peculiarly beneficial in that caſe. *Muſeum Ruſticum, vol.* VI. *pag.* 46.

TURPETH, a ſpecies of the convolvulus or bineweed. *See the article* BINEWEED.

TWIFALLOWING, or TWYFALLOWING, ploughing the ground a ſecond time, which is generally done in June.

V.

VALE, low ground; a valley.

VAN, an inſtrument to winnow corn. *See the article* THRESHING.

VASCULIFEROUS PLANTS, ſuch whoſe ſeeds are contained in veſſels divided into cells.

VAT, *or* FAT, a veſſel for holding wine, ale, beer, cider, &c. in the time of their preparation.

UDDER, that part of a cow, mare, ewe, &c. where the milk is prepared, anſwering to the breaſts in women.

VEGETABLE, a term applied to all plants, conſidered as capable of growth, *i. e.* all natural bodies which have parts organically formed for generation and accretion, but not ſenſation.

Vegetables, according to the analyſes made of them by chemiſtry, are diſtinguiſhable into two grand tribes, the acid and the alkaline; the firſt affording a volatile acid, and the ſecond a volatile alkali, upon a dry diſtillation: thus guaiacum, cedar, box, cinnamon, cloves, ſorrel, mint, balm, &c. afford an acid; but garlic, onions, horſeradiſh, ſcurvy-graſs, muſtard, &c. afford an alkali, which, rectified, is hardly diſtinguiſhable from that of animal ſubſtances, ſo as nearly to reſemble the ſpirit and ſalt of hartſhorn.

VEGETATION, the act whereby plants receive their nouriſhment and growths; of which, three principal functions are underſtood, viz. nutrition, increaſe, and generation.

From Scripture we learn, that the earth has been endued, from the beginning, with a certain ſeminal virtue to produce plants; which virtue, proceeding from God, was not confined to the firſt production of things, but extends likewiſe to all future conſequences of times; and this faculty which the earth has of producing plants, is from this commandment of the Almighty: "Let the earth bring forth graſs, the herb yielding ſeed, and the fruit-tree yielding fruit after his kind, whoſe ſeed is in itſelf upon the earth; and it was ſo." Gen. i. 11.

Philoſophers aſk, what can be that virtue the earth is ſaid to be endued with, if it be only an inherent quality whereby it produces, naturally, all ſorts of plants, without the concurrence of ſeed? or if a ſeminal virtue (or ſeed) muſt be adminiſtered to it? Some follow the firſt opinion, for this reaſon, that earth dug up from a great depth and put into pots, after a ſet time or ſeaſon, produces ſeveral ſorts of plants of itſelf without ſeed; but though this opinion be approved of by many, it has not, however, the leaſt appearance of probability on its ſide; for who (conſidering with attention the progreſs of nature, ſees the marvellous mechaniſm of the organs of plants, the whole texture of their internal as well as external parts) could be perſuaded

perſuaded to attribute it to a heavy and indigeſted maſs of clay or earth: therefore, it is more rational to ſay, that plants have their origin from ſeeds, which being taken from the firſt plants, have propagated their ſpecies by the Creator's will, as far as our times, and will continue to do ſo (particularly where they are natives) to the end of the world.

The ſun, rain, the exhalations of the earth, and the reſt of the exterior cauſes, are capable to excite a certain motion or fermentation in the boſom of the earth; but unleſs there be a ſeed which contains already the conformation of the plant, whoſe parts are unfolded by that fermentation, never ſuch fermentation or motion can give origin to the plant; therefore, we have great reaſon to think, that all plants have their origin from ſeeds, actually or potentially, ſince the firſt rudiments of a plant can be diſcovered no where elſe, nor by the naked eye, nor even by the help of a microſcope; ſo that the ſeed contains not only the coarſer matter of the plant, with its organical parts, which have the ratio of a body, but likewiſe a certain ſpirit, that is, an active and vegetative ſubſtance, which may be called the ſoul of the plant. Although, in ſome manner, it may be ſaid to ſleep in the grain or ſeed, yet when excited to motion by the heat of the ſun, the warmth of the earth, and with rain impregnated with particles of volatile ſalts, it then unfolds its parts and puſhes the embryo plant forward.

A ſprig or cutting muſt contain in it this ſeminal property, for being ſet at a proper ſeaſon, it produces a tree with all its generative parts; which it would not do were it not endued with ſome ſeminal virtues.

This generative or ſeminal faculty, is a power of the vegetative ſoul of a plant, by which it lives and produces its likeneſs for the preſervation of the ſpecies: but this faculty is not diſcernable from the ſeed itſelf, nor from the ſpirit contained therein, for as the ſeed is ſaid to be a part of ſome ſubſtance, deſigned for the production of another ſubſtance of the ſame ſpecies, it is not abſolutely neceſſary to diſtinguiſh that proliſic virtue from the ſeed itſelf, nor from the ſpirit contained in it; for after the ſeed is ſown and ſoftened by the warmth and humidity of the earth, its germ (wherein the plant is contained, as in an epitome) is unfolded by a gentle fermentation, and ariſes into a plant.

That the heat of the ſun and the temperate warmth and humidity of the earth, are the firſt principles of vegetation, appears from the ſterility or fertility of the ſoil in thoſe climates where theſe two principal agents act, or do not act in concert; ſince, in the moſt northern countries, where the humidity of the ſoil is exceſſive, and its natural warmth is too much concentered, the fermentation of the ſeed being made with too much precipitation, and without that gradation neceſſary for the eaſy and moſt perfect expanſion of the different parts of the plant, thereby they are fruſtrated of that ſtrength they ſhould have before they come out of the matrix it has been formed in to reſiſt the injuries of the air and the inconſtancies of the ſeaſons, it periſhes almoſt as ſoon as it appears on the ſurface of the earth; for although the earth has in ſome meaſure, though very imperfectly, acted its part (as it cannot alone, and without the aſſiſtance of the ſun, carry the plant to its laſt perfection) that tender parent of nature, by the obliquity of its ſituation, being reduced to the incapacity of darting its rays as favourably and abundantly in thoſe climates as he does in others more happily ſituated, cannot either help the mother earth in her pregnancy, nor rectify what ſhe has left imperfect in her productions, which therefore die almoſt as ſoon as nature itſelf is appriſed of their exiſtence.

Likewiſe in thoſe other climates ſituated quite different from theſe where the ſun, by being too profuſe of its influences, penetrates the inmoſt parts of the womb of the earth, and by its too violent and too often repeated acts, and exalting its ſalts, and evaporating its radical humidity, cauſes an exceſſive dilation of its pores, a diſunion, and but too often an intire laceration of its generative parts, ſo as to render them quite ſteril or barren, and therefore incapable to contribute to that fermentation abſolutely neceſſary for the production of plants.

On the contrary, in thoſe happy climates where the parts of the earth are ſo ſituated in reſpect to the ſun as to be under his moſt favourable aſpect, and expoſed to none but his moſt benign influences, it almoſt always continues in its natural flouriſhing ſtate, being ſeldom viſited by the moſt powerful and penetrating beams of the ſun but at thoſe regular and periodical times appointed by nature for its pregnancy, when they are neceſſary to excite her fœcundity, or to nouriſh and cheriſh her productions when once brought forth.

Suppoſe our ſeed to have been ſown in this laſt ſoil, and ſituation, the firſt things which preſent themſelves to the imagination are the ſun and earth concerting together, the one by its heat, and the other by her moiſture, how to rid the embryo of that hard tough ſubſtance it is enwrapped in, and which is the greateſt obſtacle to the burſting forth of its parts; therefore the earth, which is the firſt agent in this caſe, and which is to do the office of incubation, makes uſe firſt of its natural moiſture to ſoften the outer rind or huſk, by having it percolated through the pores or pipes of the ſaid huſk, whereby they are ſo opened and dilated as to facilitate the introduction of the different ſalts appointed to operate on the whole ſubſtance of the ſeed, by unfolding the different parts it contains, and diſpoſing them ſeverally towards aſſuming their reſpective forms.

It cannot be imagined that the earth acts alone in this firſt operation, that it could direct itſelf to action without the concurrence of the ſun, which on this occaſion excites, by a gentle warmth, the different ſalts the moiſture of the earth is impregnated with, that they may be capable to conquer the ſtubbornneſs of the huſk, by forcing themſelves into its almoſt imperceptible pores, conquering all the obſtacles, and raiſing all the obſtructions which the ſeveral ſubſtances may meet with; by this means a free paſſage being opened for ſuch a quantity of the moiſture as is neceſſary to make a due ſeparation of the huſk from the more eſſential part of the ſeed, the ſalts employed in that operation being volatilized or already fixed on that eſſential part, leave the huſk filled with nothing elſe but the lympha, which groweth turgid, and being deprived of the nouriſhment it received when united to the ſubſtance of the ſeed, begins to tend towards its deſtruction.

The following procedure in the vegetation of plants is exemplified by Malpighi in a grain of wheat; the firſt day the grain is ſown it grows a little turgid, and the ſecundine, or huſk, gapes a little in ſeveral places, and the body of the plant being continued by the umbilical veſſel to a conglobated leaf (which is called the pulp or fleſh of the ſeed, and is what conſtitutes the flour) ſwells, by which means not only the gem or ſprout (which is to be the future ſtem) opens and increaſes, but the roots begin to bunch out, whence the placenta, or ſeed-leaf, becoming looſe gapes.

The

The ſecond day the ſecundine or huſk being broken thro', the ſtem or top of the future ſtraw appears on the outſide thereof, and grows upwards by degrees; in the mean time, the ſeed-leaf guarding the roots becomes turgid with its veſiculæ, and puts forth a white down, and the leaf being pulled away, you may ſee the roots of the plant bare, the future bud, leaves, and the reſt of the ſtalk lying ſtill hid. Between the roots and aſcending ſtem, the trunk of the plant is knit by the navel knot to the flower-leaf, which is very moiſt, though it ſtill retains its white colour and its natural taſte. The third day the pulp of the conglobated or round leaf becomes turgid with the juice it has received from the earth fermenting with its own; thus the plant increaſes in bigneſs, and in its bud or ſtem becomes taller, and from whitiſh becomes greeniſh, the lateral roots alſo break forth greeniſh and pyramidal from the gaping ſheaf which adheres cloſely to the plant, and the lower roots grow longer and hairy, with many fibres growing out of the ſame; indeed there are hairy fibres hanging on all the roots, except on the tops, and theſe fibres are ſeen to wind about the ſaline particles of the ſoil, little lumps of earth, &c. like ivy, whence they grow curled about the latent roots, and then break out into two other little ones. The fourth day the ſtem mounting upwards, makes a right angle with the ſeminal leaf, the laſt roots put forth more, and the other three growing larger are cloathed with more hairs, which ſtraitly embrace the lumps of earth, and where they meet with any vacuity, unite into a kind of net-work; the conglobate or flower-leaf is now ſofter, and when bruiſed yields a white ſweetiſh juice, like barley cream; by ſtripping it off, the root and ſtem of the plant are plainly ſeen, with the intermediate navel-knot, whoſe outer part is ſolid like a bark, and in the inner more ſoft and medullary. The fifth day the ſtalk ſtill riſing puts forth a permanent of ſtable leaf, which is green and folded, the roots grow longer, and there appears a new tumour of a future root, the outer ſheath is looſened, and the ſeed-leaf begins to fade. The ſixth day the ſtable leaf being looſened, the plant mounts upwards, the ſheaf ſtill cleaving round it like a bark; the ſeed-leaf is now ſeen ſinuous or wrinkled and faded, and this being freed or cut from the ſecundine, the fleſh, or pericarpium is found of a different texture, the outer part, whereby the outſide of the ſeed or grain is heaped up, being more ſolid, but the inſide viſcular and full of humour, eſpecially that part next the navel-knot. All the leaves being pulled off, the roots torn, and the flower-leaf removed, the trunk appears, wherein, not far from the roots, the navel-knot bunches out, which is ſolid and hard to cut; above there is a mark of the ſheath-leaf, which was pulled, and underneath, as in an armpit, the gem is often hid; the hind part of the plant ſhews the breaking forth of the roots likewiſe, with the faded placenta, &c. After the eleventh day, the ſeed-leaf as yet ſticking to the plant, is crumpled and almoſt corrupted; within it is hollow, and about the ſecundine the mucus and white ſubſtance of the ſeed being continued to the navel-knot, forms a cavity, all the roots becoming longer, put forth new branches out of their ſides, the ſecond leaf withers, and its viſicles are emptied; the internodes, or ſpaces between the knots, grow longer; new gems appear, and the middle root grows ſeveral inches longer. After a month, the roots and ſtalk being grown much longer, new buds break out at the firſt knot, and little tumours bunch out, which at length break out into roots.

Thus, according to Malpighi, in this ſhort ſpace of time, the plant paſſes through all theſe various changes and mutations, which, though his obſervations may be real as here repreſented, yet it does not happen with ſuch celerity in all ſorts of plants, though in ſome kinds all theſe variations may come to paſs in a ſhorter time.

The plant carried thus far, it ſtill wants food for the future preſervation of its vegetative life, which being deprived of ſuch nutriment, it cannot exiſt; of which naturaliſts are ſo ſenſible, that their common opinion is, that water is the great vegetable food, which they endeavour to confirm by repeated experiments, eſpecially by that made on a ſprig of baum, mint, &c. which being ſet in a phial of pure water, without any mixture of earth, grow and put forth roots, leaves, and branches; without conſidering, that thoſe ſorts of plants being of a ſhort duration, the juices which they have received from their mother earth in their firſt formation circulating through their veſſels, being continually recruited by the ſalts the water they are ſet in is impregnated with, together with thoſe they receive continually from the ambient atmoſphere, are more than ſufficient for the ſupport of their ſhort life in the water, which ſubſiſts no longer than that the water continues to ſupply them with ſalts, of which when once exhauſted, it grows viſcous, obſtructs the pores of the veſſels, and hinders thereby the admiſſion of ſalts even from the atmoſphere, imbecillitate by degrees the functions of the vegetative ſoul, which being forced for ſome time to feed on its own ſubſtance, becomes at laſt enervated and impotent, whereby the plant withers and dies for want of food, unleſs the water is changed before it comes to the laſt period, which appears at its growing offenſive to the ſmell; even that precaution becomes uſeleſs, at leaſt for the greateſt part.

Thoſe ſalts the water is impregnated with, being heterogeneous to thoſe which enter into the compoſition of the juices, which circulate through the veſſels of the plant, have ſoon, by diſordering the whole frame of that mechaniſm, procured the extinction of the plant.

The great quantity of oleaginous particles thoſe ſorts of plants are compoſed of, which keep their pores extremely dilated for the admiſſion of ſalts and other nutritive particles, contribute much towards the production of this phænomenon; but in plants of a cloſer texture, whoſe pores are ſo exiguous as not to be forced, but by the empetuoſity of ſalts exalted and volatilized, beſt by the warmth of the earth and the heat of the ſun, this experiment is of no effect; therefore, water cannot be ſimply conſidered as the great vegetable food, although it has a very conſiderable ſhare in the nutriment of plants: but were it water alone, to which vegetables owe their increaſe, there would be no need of manures nor changing the kinds. The rain falls in all places upon the moſt barren land, as well as on the moſt fertile; nor could there be any reaſon why the ſame field ſhould yield a large crop of wheat one year, and not the next, ſince rain ſhowers down nearly alike on the earth.

VELLING, ploughing, or cutting up the turf, or upper ſurface of the ground in order to its being burnt. *See the article* BURNBAKING.

VENTILATOR, a machine by which the noxious air of any cloſe place (as an hoſpital, jail, ſhip, chamber, granary, &c.) may be changed for freſh air.

The noxious qualities of bad air have been long known, though not ſufficiently attended to, in practice; but it is

to

to be hoped, that the indefatigable pains taken by Dr. Hales, to ſet the miſchiefs ariſing from foul air in a juſt light, and the remedy he has propoſed by the uſe of his ventilators, will at length prevail over that unaccountable ſloth or obſtinacy, which, where particular intereſts are not concerned, ſeems to poſſeſs the generality of mankind, and which rarely allows them to give due attention to any new diſcovery.

The ventilators invented by that ingenious gentleman conſiſt of a ſquare box, ABCD (plate XXVI. fig. 7.) about ten feet long, five wide, and two deep; in the middle of which is placed a broad partition, or midriff, made to move up and down, from A to C, on hinges at the end E, by means of an iron rod ZR, fixed to the midriff at Z.

Another box, of the ſame ſize with the former, having a like midriff, bar, &c. is placed near the former (fig. 8.) with its rod, RZ. Both theſe rods are fixed to a lever FG, moveable on the center O; ſo that by the alternate riſing and depreſſing of the lever FG, the midriffs are alſo raiſed and depreſſed alternately, by which means theſe double bellows are at the ſame time both drawing and pouring out the air.

That the midriffs may be rendered lighter, they may be made of four bars, lengthwiſe, and as many placed acroſs them, each about three inches broad, and an inch thick, the vacant ſpaces being filled up with thin pannels of fir board.

In order to make the midriffs move with greater eaſe, and without touching the ſides of the boxes, there is an iron regulator NL (fig. 7.) fixed upright to the end AC of the box. As very little air will eſcape if the edges of the midriff be within one twentieth part of an inch from the ſides of the box, there is no neceſſity for leathern ſides, as in common bellows. The end AC of the box muſt be ſomewhat circular, that it may be the better adapted to the riſing and falling of the midriff; and at the other end of the midriff a ſlip of leather may be nailed over the hinges.

To the ventilators above deſcribed, eight valves are adapted for the air to paſs through; theſe valves are placed at the hinge end IQ, fig. 8. numbered 1, 2, 3, 4, &c. The valve 1 opens inward, to admit the air to enter, when the midriff is depreſſed at the other end, by means of the lever FG; and at the ſame time the valve 3, in the lower ventilator, is ſhut by the compreſſed air, which paſſes out at the valve 4: but when that midriff is raiſed, the valve 1 ſhuts, and the air paſſes out at the valve 2. The ſame is to be obſerved of the valves 5, 6, 7, 8, of the other box; ſo that when, by the motion of the lever FG, the midriffs are alternately riſing and falling, then two of the ventilators are conſtantly drawing in the air, and two of them at the ſame time are blowing it out at their proper valves, the air entering at the valves 1, 3, 6, 8, and paſſing out at the valves, 2, 4, 5, 7. To the ventilators, before the valves, is fixed a hook QQMM (fig. 9.) as a common receptacle for all the air that comes out of theſe valves, which air is conveyed away through the trunk P, paſſing through the wall of a building, &c.

It would be foreign to the intention of this work to point out the various uſes of theſe machines in extracting foul air out of ſhips, hoſpitals, &c. but we muſt not omit the following.

Experiments on the preſervation of corn by ventilation.

M. Duhamel cauſed a caſe, or little granary of preſervation, to be made of oak plant two inches thick, forming a cube of five feet every way. At ſix inches from the bottom was a flooring, or ſecond bottom, of lattice work, placed upon joiſts five inches thick, and covered with a ſtrong canvas. This ſmall granary was filled quite full of good wheat, of which it contained 94 cubic feet, weighing 5040 pounds. It was covered with good oak planks, ſo cloſely joined, that neither rats, mice, or even the ſmalleſt inſects could get in; leaving only ſome vent-holes, with trap doors, or covers, fitted very exactly to them, as mentioned before.

This corn, laid up without having been dried at all by fire, was not ventilated more than ſix days in a year, which was ſufficient to keep it ſo well that the beſt judges allowed it to be as good as could be. Even when the bellows had not been worked for ſeveral months, the corn was ſtill allowed, by good judges, to look and ſmell perfectly well: but they objected, that it did not handle well, that is, that there was ſome little dampneſs in it. The bellows were worked for half a day, and this objection was entirely removed.

This wheat was old, and had been as well dried as any corn generally is in a common granary: therefore it being ſtill damp, at the end of a conſiderable time, ſhews the neceſſity of taking away the ſuperfluous moiſture, and of reducing our corn to the ſame degree of dryneſs, as that of the hotteſt countries, in order to preſerve it in great bodies.

Experiment on ninety-four cubic feet of wheat.

In May, 1743, ninety-four cubic feet of wheat were put into one of the little granaries before-mentioned. It was of the harveſt of 1742, of an excellent quality, perfectly clean, and ſo dry, that a ſmall parcel of it which was put, for a trial, into a ſtove heated to fifty degrees of M. de Réaumur's thermometer (123 of Farenheit's) loſt but one fixteenth of its weight. This wheat was well cleanſed from duſt, and depoſited in the granary without being dried by fire.

During the firſt three months, it was ventilated for eight hours once a fortnight: during the reſt of the year 1743, and all 1744, it was ventilated once a month: all the year 1745, and part of 1746, it was ventilated half a day once a month; and after that, but once in two or three months.

In June 1750, the granary was emptied, and the wheat looked and ſmelt very well, but felt a little rough in the hand, becauſe, not having been ſtirred for ſix years, the little hairs that are at the extremity of the grain, and the particles of the bran, were roughed up: but after paſſing twice through the wind ſcreen, that objection was entirely removed. *See the article* THRASHING.

This corn was eight years old, during ſeven of which it was preſerved in one of M. Duhamel's ſmall granaries, without any ſenſible diminution, and without any damage from vermin or inſects: we cannot ſay abſolutely, without any expence, becauſe a man was employed from time to time to ventilate it. But this was a very trifling charge, and may be reduced almoſt to nothing, by working the bellows with ſwifts like thoſe of a mill.

Expe-

Experiment on ſeventy-five cubic feet of new wheat, extremely moiſt, grown, and which had already contracted a bad ſmell.

The harveſt of 1745 was very rainy: almoſt all the wheat of that year was grown in the ear; the ſheaves were extremely wet when they were houſed; the grains adhered ſo cloſely to their huſks, that they were greatly bruiſed by the flail; and if they were left but a very little while upon the barn-floor, before they were cleanſed, they heated, and contracted a ſmell like that of pigeon's dung: in ſhort, they were ſo very moiſt, that they loſt an eighth part of their weight when dried in a ſtove heated to fifty degrees of M. de Réaumur's (one hundred and twenty-three of Farenheit's) thermometer; and when laid up in the common granaries, in the uſual way, they were always in a ſtate of fermentation, though but a foot thick, and turned every fourth or fifth day.

Seventy-five cubic feet of this grown wheat, which ſmelt very ill, and was ſo moiſt as to wet the floor of the granary where it laid but a few days, were put, in this condition, and without being dried by fire, into one of M. Duhamel's little granaries, with ſmall hopes of ſucceſs.

As this corn was very hot when put into the granary, it was ventilated three or four times the firſt week, and once a week during December and January: and as it had then loſt great part of its bad ſmell, it was ventilated but once a fortnight from that time till June. Then perceiving, by thruſting his hand into the top of the heap, that it heated, and concluding that it was going to be entirely corrupted, M. Duhamel ordered the granary to be emptied: but after the depth of about a foot had been taken from the top, he was greatly ſurpriſed to find the reſt cool, with very little bad ſmell, and drier than that which was preſerved in the common granaries.

The reaſon why the top of this corn was the worſt, was, undoubtedly, that the moiſt vapours were always forced upwards in ventilation. It therefore might, perhaps, have been kept very well, if, inſtead of emptying the granary, it had been ventilated oftener: for this would, probably, have dried away the remaining moiſture, even at the top, as the following experiment will ſhew. But however that might have been, this teaches us one important thing, which is, that the top of the heap is moſt ſubject to heat in this ſort of granary: ſo that if the grain taken out of the vent-holes is in good condition, it may be concluded that the reſt is ſtill better.

Experiment on five hundred and fifty-five cubit feet of wheat, very damp, mixed with ſmut, and which had contracted a bad ſmell.

The wheat of the year 1750 grew in almoſt continual wet; the harveſt was very rainy; and the ſame weather continuing all the year 1751, no pains that could be taken to turn the corn laid up in the common way, could dry it, or prevent its heating and contracting a bad ſmell. The wheat of this crop was likewiſe mixed with a conſiderable quantity of blighted and ſmutty grains, which always contain a great deal of moiſture, doubly difficult to be exhaled from them, and which ſoon makes them contract a bad ſmell, which they ſpeedily communicate to the ſound corn.

Five hundred and fifty-five cubic feet of this wheat were depoſited in one of M. Duhamel's granaries of preſervation, after being cleanſed with ſuch perfect care, that ſcarce any mark remained either of blight or ſmut among it; though theſe faulty grains amounted to near a ſixth part of the crop. But there ſtill remained a fine duſt, or powder, occaſioned by the moiſture, ſo cloſely adherent to the corn, that it could not be taken off by any means.

This wheat was laid four and a half or five feet thick in one of theſe granaries, the bellows of which were worked by a wind-mill; and as there was no want of wind during all the year 1751, and till the ſpring of 1752, the corn was often ventilated, without trouble or expence; by which means it was not only well dried, but alſo cleared of great part of its bad ſmell. It was indeed, when taken out of the granary, very full of duſt, which had fallen off the grains as their moiſture was exhaled: but this was then eaſily ſeparated by proper ſcreening, and the wheat proved ſo good, that the bakers bought it at the higheſt market price.

This experiment proves, that even very moiſt corn which has a great diſpoſition to ferment, may be preſerved by ventilation only: and as to the ſmutty grains with which this was mixed, the reverend Dr. Hales, after rightly obſerving that kiln-drying is apt to make wheat grind unkindly, propoſes the following method of drying ſmutty corn, after it has been waſhed; cold air not hurting it, as kiln-drying is found to do. "That I might be well aſſured, ſays that friend to all mankind, of the good effect of thus drying ſmutty corn; having procured a quantity of very ſmooty wheat, which weighed ſeven pounds and fifteen ounces, on the twenty-ſixth of May, at five in the morning, it was waſhed clean in four ſeveral waters, which was done in a few minutes, and was then laid to drain in an oat-ſieve, till half an hour after five; when it had increaſed in weight, by wetting, ten ounces, beſides the moiſture that was equal to the weight of the ſmutt-balls and ſmut that was waſhed from the wheat. It waſted but two ounces and an half, by the firſt two hours ventilation; two ounces and five drachms in the ſecond two hours, viz. from eight to ten; in the next ſix hours, viz. from ten to four in the afternoon, it waſted at the rate of four ounces every two hours; from four to ſix, two ounces and an half, and from ſix to eight, one ounce and an half: in all, about twenty ounces; ſome allowance being made for what corn was waſted by handling and biting ſome of it from time to time. It was ventilated in theſe fourteen hours with about forty thouſand gallons of air, which paſſed upwards through it, and made it ſufficiently hard and dry, ſo as to be fit for grinding: it was well coloured, and handled well; and, from ſtinking, as ſmutty wheat does, it became much ſweeter. The viſible dewy moiſture was blown off in three hours; but it continued damp and cold to the feeling till two o'clock, when ſome little duſt began to fly off it.

"And whereas it waſted off much leſs moiſture during the firſt four hours ventilation, when it ought to have waſted the moſt, on account of its being then wetteſt, this was owing to the foggy hazineſs of the morning: which as it went off, and broke out into fine warm ſunſhine, towards ten o'clock, ſo the air being thereby become dry, it imbibed moiſture more ſtrongly from the corn: and that this was the true caſe of the difference, is farther confirmed by a like experiment which I had before

made on a gallon of wheat, April the firſt, there being then a very dry north-eaſt wind.

"It will be adviſable to begin to ventilate corn as ſoon as poſſible after waſhing, that the moiſture may have the leſs time to ſoak in: for the leſs moiſture ſoaks in, ſo much the ſooner the corn will dry.

"If the moiſture is ſo eaſily carried off from wet wheat, by ventilation, this method will doubtleſs much improve what is called cold wheat, viz. ſuch as is grown, and has been houſed in a cold wet ſeaſon; and will therefore ſoon carry off the moiſt vapours which ariſe from corn, and which cauſe it to heat and grow muſty."

Other experiments on the preſervation of corn by ventilation.

The prior of the royal abbey of St. Stephen in Caen, filled a granary of preſervation twelve feet wide, thirteen feet long, and ſix feet deep, which forms a parallelipipede of nine hundred and thirty-ſix cubic feet, conſtructed according to M. Duhamel's directions, with wheat that had been kept all the winter in a common granary. It was cooled from time to time by two bellows, which two men worked by means of a leaver; and though the place where this granary of preſervation ſtood, was neither ſo dry nor ſo airy as might have been wiſhed, the corn kept perfectly well in it.

In the beginning of September 1754, M. Vandusfel filled one of M. Duhamel's granaries of preſervation, ſeven feet ſquare and ſix feet deep, with good wheat, undried. It heated a little at the end of eight days; but two men, with a ſmall double ventilator, cooled it in two hours time. It began to heat again about a week after, when he repeated the ſame operation, which cooled it preſently. By the twentieth of October it was quite cool, though it had not then been ventilated for fifteen days; and according to a letter of his writing to M. Duhamel, dated the fourteenth of October, 1756, it ſtill continued in the ſame good condition. Corn of the year 1754 and 1755, not dried, but only ventilated, had likewiſe kept with him as well as could be wiſhed.

VERJUICE, a liquor obtained from grapes or apples too acid for wine or cider. It is generally made in England from the juice of the crab, or wild apple.

VERMIN, a collective name including all kinds of ſmall animals, that are troubleſome to men, beaſts, corn, fruits, &c.

VERNAL, ſomething belonging to the ſpring ſeaſon.

VETCH, the name of a well known plant, much cultivated in many parts of England, and of which there are ſeveral ſpecies.

Some ſorts of this plant, the ſeeds of which ripen in autumn, grow naturally in moſt parts of England, in ſhady places among buſhes, and by the ſides of woods. The roots of theſe are perennial; but their ſtalks are annual, weak, and grow to ſo great a length (for they will climb up to the height of ſix or eight feet wherever the tendrils which proceed from the end of their leaves can lay hold of boughs, branches, or the ſide of a hedge, to ſupport them,) that they are hardly fit to be cultivated in the field, though ſome writers have recommended them for this purpoſe: for as they cannot be ſupported there, they will trail ſo much upon the ground, that they will be apt to rot: nor do their ſhoots, which are leſs ſucculent than thoſe of the vetch commonly raiſed, grow to a ſufficient height to be cut for uſe till late in the ſpring, when there is little want of green food for cattle.

Mr. Miller, after ſowing for many years the common vetch or tare, which is much cultivated in the fields for fodder, ſeems to think that which has black ſeeds, a diſtinct ſpecies from the white: for he nas never found either of them vary. Both theſe are annual, and periſh ſoon after they have perfected their ſeed. Their ſtalks are angular, ſtreaked, and hairy: they are weak, and want ſupport, and generally trail upon the ground when they do not find any thing to faſten themſelves to. Their leaves are compoſed of ſeveral pair of blunt lobes, and are terminated by tendrils. The flowers, which are pretty large, proceed from the wings of the ſtalk, and ſit very cloſe to the baſe of the foot ſtalks of the leaves. Two of theſe flowers generally ſpring from the ſame joint: thoſe of the black ſeeded ſort are purple, and thoſe of the white ſeeded are white. They appear in June and July, and are ſucceeded by erect pods, containing three or four round ſeeds in each, whichripen in Auguſt and September.

The white vetch is rather the more ſucculent plant of the two, and therefore it is beſt for fodder: but many are unwilling to cultivate this ſort, becauſe their ſeeds, being white, are much ſooner diſcovered by rooks and other birds, than thoſe of the black, which bear a nearer reſemblance to the colour of the ground. This objection may, however, be eaſily removed, by ſowing them in drills, and then covering them carefully, inſtead of the uſual method of ſcattering them with a broad-caſt, and plowing them in lightly.

The ſmall black-ſeeded vetch, which ſome call rathripe, and others pebble, goar, or ſummer vetch, is much tenderer than either of the former, and therefore leſs cultivated. This muſt always be ſown in the ſpring: whereas the others may be ſown in ſpring or autumn.

But another ſpecies of vetch, viz. the Siberian, hardly known, to the generality of farmers in this country, bids fair to become, perhaps, the moſt uſeful of all for fodder; for its ſtalks grow to a great length, and are well furniſhed with leaves, which do not decay in autumn, like thoſe of the other ſorts, but continue green all the winter, in defiance of the hardeſt froſt: ſo that in February and March, when there often is a ſcarcity of green fodder for ewes and lambs, this may be of ſingular ſervice, eſpecially if theſe plants are ſupported from trailing upon the ground. Their flowers, which appear in July, are of a light blue colour.

This, like our common vetch, may be ſown in the ſpring, or in autumn; and when the plants are come up, they will not require any other culture than keeping them clear from weeds; a work which, if the ſeeds are ſown thin in rows four feet aſunder, as Mr. Miller rightly adviſes, may be eaſily done with the Dutch hoe, while they are young, and afterwards with the hoeing plough. By this thin ſowing, the ſtalks of theſe vetches, which ſend out many branches, and extend very far, will be kept from matting ſo cloſely together as to rot each other by excluding the air; and by earthing up their ſtems in the ſame manner as ſhould be done for peas and beans, they will be greatly ſtrengthened, their leaves will grow the larger and more ſucculent, and they will conſequently yield an increaſed quantity of fodder. The repeating of this as often as it may be found neceſſary to deſtroy the weeds in ſummer, which may be done at a very ſmall expence, and is particularly proper when the growth is intended for the green food of cattle, will be attended with the farther important advantage of preparing the ground thoroughly for whatever other crop may afterwards be put upon it.

As

As the plants of this kind of vetch will not be in danger of being hurt by froſt, they ſhould not be cut till the ſpring, when the beſt way will be to take them as they may be wanted, green, for the feeding of ewes: but ſome of them ſhould be left untouched, for ſeeds; for if thoſe which are cut do ſhoot out again, they will flower ſo late in ſummer, that their ſeeds will not ripen, unleſs the autumn proves very warm. A better way will therefore be to ſow a proper quantity of ſeeds for this purpoſe in a ſeparate ſpot of ground: becauſe, when the other is cut, the ground may be plowed for other crops; and if the ſeaſons ſhould be ſo mild as to produce a ſufficiency of green food independent of this, the vetches may be plowed into the ground, to which they will be an excellent dreſſing for other crops.

Mr. Miller, who has a high oponion of this ſort of vetch, and whoſe recommendation of it ought to have very great weight, is now beginning to try it in the field, where he has not yet had experience of its culture; but the experiments which he has made with it for ſix years paſt, on ſmall patches of it ſown in gardens, in different ſituations, have fully anſwered his expectation: for he has found theſe plants continue in great verdure in all thoſe places, when moſt of the perennial plants in the ſame ſituation have ſuffered greatly by the froſt, and could have cut from only eight of them as much fodder as would have been equivalent to half a truſs of clover.

Vetches are generally ſown either in autumn, or early in the ſpring: but the beſt time, in this country, is toward the beginning of Auguſt; becauſe the rains which uſually fall about that ſeaſon will bring them up in a ſhort time, and the plants will get ſtrength before winter, and be fit to cut for the food of cattle early in the ſpring, when green fodder is moſt wanted: and if they are deſigned for ſeed only, theſe early ſown vetches will come early into flower, and their ſeeds will ripen early, ſo that they may be cut and ſtacked in good weather, which is a great advantage; for thoſe which ripen late, are often ſtacked or houſed wet, and then their ſeeds frequently ſprout in the mow, and are ſpoiled.

Vetches will do well in almoſt any ground; not accepting even ſuch as can ſcarcely produce any other plant. The common method of ſowing them is in broad-caſt, ploughing them lightly in, as was obſerved before; and the uſual allowance is two buſhels of ſeed for an acre of land; though ſome ſow two buſhels and an half. Either of theſe practices may do well enough for thoſe vetches which are intended to be cut for fodder in the ſpring; but when they are ſown with a deſign to let them ſtand for ſeed, it will certainly be much better to ſow them in drills, in the ſame manner as is practiſed for peas; and in this caſe leſs than half of the abovementioned quantity of ſeed will be ſufficient: for the rows ſhould be at leaſt three feet aſunder, that the hoe-plough may have room to go between them, to deſtroy the weeds, and earth up the plants, which, when thus managed, will produce a much greater crop, and ripen better and earlier, than in the common way. Theſe drills ſhould be of about the ſame depth as for peaſe, and the ſeeds ſhould be ſcattered at about the ſame diſtance in the drills, in which they ſhould be carefully covered over as ſoon as they are ſown; for otherwiſe the rooks will diſcover them; and when thoſe voracious creatures once find the rows, they will ſpeedily deſtroy them intirely, if they are not carefully watched. The preventing of this is another advantage which attends the ſowing of vetches early in autumn, rather than in the ſpring: becauſe there is more food for rooks and pigeons in the open field in the former of theſe ſeaſons, and the plants will then appear much ſooner above ground. Toward the end of October, by which time the plants will have acquired conſiderable ſtrength, the horſe-hoe ſhould begin to work between the rows, provided the weather be dry: and in doing this, particular care ſhould be taken to lay the earth up as high to the ſtems of the plants as can poſſibly be, without covering their tops. This will help to ſecure them againſt froſt, and clear the ground of weeds at leaſt till March, when the plants ſhould be earthed up a ſecond time, and the intermediate ſpaces between their rows be cleaned again, in the ſame manner as before. This will make them grow ſo vigorouſly, that they will meet and cover thoſe ſpaces in a little time: whereas thoſe ſown in the ſpring will not grow to half this ſize, and will be very late in flowering.

When vetches are intended only for fodder, of which they generally afford two good crops in the year, in hot countries, or when the farmer deſigns them for plowing in, by way of manure, they need not be ſown in drills, or huſbanded in the manner directed: the common broad-caſt way will then do well enough: but ſtill it is moſt adviſable, in either caſe, to ſow them early in autumn; becauſe, in the firſt place, they will produce the deſired green fodder much earlier in the ſpring; and in the ſecond, they will be fit to plow in much ſooner the following year, and thereby have time properly to meliorate the land, and prepare it to receive the enſuing crop, which they are generally allowed to do even more effectually than peas. Stiff clays are peculiarly benefited by this dreſſing: but it ſurely is bad huſbandry to ſow vetches for green fodder, where lucerne will thrive; becauſe this laſt will yield greater plenty of ſtill more nouriſhing food.

In ſome countries, eſpecially abroad, they mix oats with their tares or vetches, an equal quantity of each, and ſow them in February. The vetch, ſupported in ſome meaſure by the oat, grows the higher for it: and, about the middle of May, this mixture is mowed, and given to horſes and other cattle, which it fattens greatly. Mr. Mortimer likewiſe thinks it a good way to ſow horſe-beans and tares together: their ſeeds are eaſily parted with a riddle: and another obſervation in which he agrees with the Maiſons Ruſtiques, is, that more vetches ſhould not be ſown at any one time, than can be covered the ſame day, becauſe the dew is apt to ſpoil them: conſequently they ſhould not be ſown till two or three hours after the riſing of the ſun; by which time the moiſture will be exhaled from off the ſurface of the earth. But though their ſeeds cannot bear dampneſs, which would ſoon rot them, their plants, eſpecially in ſandy land, often periſh in dry years, for want of water. To make them flouriſh well, they require a ſhower of rain every ten or twelve days. One plowing to turn in the ſtubble of the preceding crop, and another at the time of ſowing, are ſufficient for this plant: but thoſe who give only one plowing, which is when they ſow, and afterwards harrow in the ſeed, neither have, nor can expect, an equally good return.

When vetches are cultivated for their ſeeds, they ſhould be cut ſoon after the pods turn brown, and ſtacked as ſoon as they are dry: for if they are ſuffered to lie out in the field, till they receive wet, and there then comes a hot

day, moſt of the pods will burſt, unleſs they happen to have been blighted; in which caſe they will not open ſo eaſily. Their haulm, when dry, and threſhed, is eſteemed good food for cattle, and ſome ſay that their ſeeds are as good for horſes, as beans; which, if true, ſhould render them the more valuable, becauſe theſe will grow on the lighteſt ſandy land, where beans will not thrive; and may therefore, as Mr. Miller obſerves, be a good improvement to ſome counties in England where they do not even attempt to cultivate the bean. About three loads from an acre are reckoned a good crop.

Vetches, when threſhed out, will be as good for ſowing at the end of five or ſix years, as at firſt, if care be taken to turn them in the heap from time to time. Mr. Mortimer cautions the huſbandman to lay them by themſelves in ſome convenient place, ſeparate from his other corn, becauſe they will otherwiſe be apt to foul it.

It is commonly ſaid, that the farmer cannot ſow any thing more profitable than vetches; for that, beſides inriching the land, a load of them will go farther than two loads of hay: but Mr. Liſle has a calculation tending to prove, that an acre of broad clover is worth twenty ſhillings a year more than an acre of any vetches, and that the clover ſhould therefore be preferred, wherever the ground will bear it well.

"It would certainly, ſays Mr. J. Smith, an ingenious farmer of Eſſex, be of great national advantage, could our ſtock of cattle and ſheep be encreaſed without diminiſhing the quantity of our lands that are in tillage.

"This can no otherways be done, but by encouraging the growth of artificial paſtures, which the farmers have of late years fallen into.

"The turnip huſbandry is not of very old ſtanding in this iſland, yet has it made a very rapid progreſs. The immenſe utility of it, when properly practiſed, cannot but be evident, even to an ignorant common farmer, on the ſligheſt inſpection. This evident utility of it has occaſioned its being almoſt univerſally practiſed in the counties of Norfolk, Suffolk, and Eſſex, whence it has ſpread to other parts of England, and is of late even adopted in Ireland, where, I am informed, the gentry are very intent on improving their eſtates.

"The coleſeed plant has alſo its utility, and in many places is as univerſally ſown as the turnip. I have, myſelf, very often raiſed this crop, as well for feeding ſheep, &c. as for the ſake of its ſeed, and have had no little ſucceſs in this huſbandry, being very fond of it, as coleſeed is an excellent crop to overpower, choak, and deſtroy weeds.

"I wiſh the burnet-graſs, ſo ſtrongly recommended, may anſwer every purpoſe that is expected from it: it ſeems to promiſe very fair from the accounts given of it by Mr. Rocque; and if it has not too much prejudice to encounter withal, it may probably ſucceed, and the culture of it become as univerſally adopted, as is that of the turnip, or coleſeed plant, already mentioned.

"So much in general; but the particular reaſon of my now writing to you, was to recommend to the induſtrious farmer the cultivation of vetches as food for cattle.

"I have often ſown this crop with great ſucceſs, to prepare my land for wheat, and have always found that by growing to a large cover they deſtroy and choak up a great number of weeds, which would otherwiſe do me immenſe damage: indeed, I think them, for this purpoſe next in rank to a hoeing crop.

"When I ſow vetches before wheat, I always, in the ſpending my crop, have regard to the condition of my land. If my land is not in good heart, but wants mending, I not unfrequently fold my ſheep on it, and feed off my crop in the field; but if it is inclined to be rank, or the wheat which is ſowed on it, is apt to run much to ſtraw, I often cut my vetches green, and feed my horſes in the ſtable with them. I find no food agree better with them; they thrive well, grow fat, and are always in good health and ſpirits when thus fed.

"I ſometimes alſo mow my vetches when they are in bloom, and make them into hay, in the ſame manner I manage my clover and meadow graſs; all which I leave in graſs cocks in the field, whilſt it is haying, very ſeldom ſpreading it, for fear of rain; and after two or three turns it is generally fit to carry.

"The great art, in making hay of vetches, is to contrive in ſuch ſort, that the leaves do not drop off the plants, which, if left too long, or dried too ſuddenly, they are apt to do; and the farmer is to underſtand, that great part of the peculiarly nouriſhing quality of the hay reſides in the leaf.

"I ſay peculiarly nouriſhing, becauſe almoſt every kind of cattle, as horſes, oxen, cows, and ſheep, is fond of it, and they all thrive on this food amazingly: this I have often experienced, and moreover obſerved, that they make no waſte even of the ſtalks, which they eat with an appetite.

"In this manner I manage for my hay, when I am inclined to have it very fine and fit for my cows and ſheep; and in this manner it is no difficult matter to get it in good order, ſweet, and wholeſome: but when I intend it only for my horſes, I generally let my crop ſtand ſomething longer; that is, till the kid, or pod, is formed, and the ſeed about half grown within it.

"When the hay is made in the laſt way, the buſineſs is much more tickliſh, and conſtant obſervation muſt be made to ſee when the crop is in proper order to cut, becauſe if it is left too long, the ſtalks grow hard and ſticky, and the leaves are apt to drop off.

"This hay is more nouriſhing, when cut in this laſt method, than I can well deſcribe: it anſwers both for hay and corn; and with this food my horſes will be in good fleſh, health, and ſpirit, and be able to do a great deal of work. I have often proved this to be true, and can therefore the better venture to aſſert it.

"I have ſtill another method of making theſe vetches into hay, which is to leave the crop, till the ſeed is grown to its full ſize in the pod, though not ripe: I then mow them, and, when dry, threſh them on a cloth in the field; by which means I procure a conſiderable quantity of pigeons meat, which fetches me a tolerable good price; and this pigeons meat ſells better at market, than if the vetches had ſtood till the ſeed was thoroughly ripe: for by cutting the crop when the ſeeds are barely full grown before they begin to harden, they ſhrink in the drying, and thereby become of a ſmaller ſize than they are by nature, and conſequently more proper food for pigeons than if they were larger.

"I own, the hay in this laſt method is not quite ſo good, as many of the leaves will, in ſpite of all the care that can be taken, drop off, and the ſtalks will be a little

ſticky: yet, after all, it ſerves very well for my ordinary cattle, and even for my plow and cart horſes, with the aſſiſtance of a few oats.

"Vetches are a very good plant to ſow thick on land, and when they have formed a perfect cover, to plow them in, in order to the land's being ſown afterwards with wheat on one plowing. In this intention they anſwer to the full as well as buck-wheat, or clover.

"When a farmer intends to plow in his vetches, I would by all means adviſe him to do it ſome weeks before he ſows his wheat, that they may have time to ferment and rot, or the conſequences may be fatal to this crop: I once, myſelf, loſt the chief part of a fine field of wheat by this overſight." *Muſeum Ruſticum*, *vol.* II. *pag.* 169.

"Vetches, ſays a gentleman farmer of Surry, are a grain often overlooked by the farmer; yet are they, when properly cultivated and applied to proper uſes, highly valuable and very beneficial.

"They are a very hardy grain, and reſiſt the ſeverity of a ſevere winter better than moſt other crops; beſides which, they have the additional advantage of growing in almoſt any ſoil; but then the farmer is to expect a produce in proportion to the goodneſs of his land.

"I would by all means adviſe, where it is intended for early feed, or to ſtand for ſeed, that the ſmall winter vetch be cultivated in preference to every other ſort, becauſe it is not only hardier, but alſo, being ſown about Michaelmas, it is forwarder, to ſerve as fodder, or will be earlier ready to mow for ſeed, which is no inconſiderable advantage; for the vetch being a ſucculent plant, and forming a very thick cover on the land where it is a full crop, it will be in danger of rotting inſtead of drying, if it ſhould be cut late, or the harveſt weather ſhould be very rainy; but if the winter vetch is ſown early, it will, in general, be fit to mow in July, or the very beginning of Auguſt, when there is leſs danger.

"Few farmers allow more than one ploughing for vetches: I always allow two, notwithſtanding what the neighbouring farmers tell me of turning the freſh ſoil again down to the bottom of the furrow: I find my advantage in this practice, and ſhall therefore continue it.

"I have generally experienced the firſt week in October, if the weather is fine, to be the very beſt time for ſowing vetches; and I allow only two buſhels of good ſeed to every acre, which I find full ſufficient.

"I ſow them broad-caſt on the rough land, as the plough leaves it after the ſecond ploughing, taking care to harrow the field length-ways and croſs-ways, in order to cover the ſeed the better; after which I paſs over it a roller, heavier or lighter, according to the nature of ſoil and the dryneſs of the weather, obſerving, that if the weather is dry, and the ſoil light, I uſe a heavy roller, in order to cloſe the pores of the light earth; but if the ſoil is ſtiff, and the weather damp, I uſe a lighter roller, leſt I ſhould knead and cruſt the field over, ſo as to ſtop the young ſhoot of the vetch.

"This crop will, in general, choak all the weeds that come up with it; but this muſt, however, be underſtood of the ſmaller ſorts, for if there are many large rampant weeds, it will be neceſſary to have them extirpated with the hook.

"Vetches afford excellent food for ſheep in the ſpring, make cows give a great deal of good milk, and horſes are fonder of them, cut green, than almoſt any other food.

"The beſt way is to cut them freſh and freſh every morning as they are wanted; and if the farmer has occaſion for them for this uſe only, he may ſow in the ſpring, to great advantage, the large vetch, at different times; by which means he will have a ſucceſſion of crops, which, to give green to his cattle, he ſhould always cut juſt before the plant flowers, for it is then in its tendereſt and moſt ſucculent ſtate, and will afford moſt nouriſhment; whereas, if he leaves it till the ſeeds are nearly ripe, the ſtalks harden, grow ſticky, and are of far leſs value; beſides that many of the lower leaves will, by this time, be withered, or dropped off, and entirely loſt.

"I muſt not conclude without mentioning an important uſe to which vetches are often applied; I mean, a full crop of them is frequently ploughed into the land as manure, to prepare it for a ſucceeding crop of wheat.

"When vetches are ſown with this intention, I would recommend the large ſort, and that four buſhels of good ſeed ſhould be uſed, to be ſown broad-caſt twice in a place: but my way of ſowing it is ſomewhat peculiar when I mean to plough it in; therefore I think it may not be amiſs to relate it.

"Moſt farmers ſow it by caſting it twice in a place, immediately after the land is ploughed, and then harrow and roll the field; but I proceed as follows.

"As ſoon as the field is plowed, I ſow two buſhels, broad-caſt, on every acre; after which I harrow it length-ways and croſs-ways. When this is done, I ſow the remaining two buſhels, and then harrow it twice again with a pair of heavier harrows, and finally ſcratch it twice over with light harrows to raiſe a mould, concluding my work by paſſing a roller over the whole field. By this management I ſcarcely ever miſs of a full crop, which covers the whole land, choakes the weeds, and ſerves as excellent manure for the wheat that is to follow.

"I have always found that this huſbandry ſucceeded beſt in light, hungry, ſandy, or gravelly loams; and a brother of mine, who lives in Bedfordſhire, tells me it does very well on a chalky ſoil, provided there is any heart in it.

"The time I chooſe to plough in the vetches is juſt after the bloſſom fades, and the kid begins to form; and it is really ſurpriſing to ſee what a ſtrong fermentation they raiſe in the ſoil.

"I have ſometimes had my crops ſo heavy that I have been obliged to mow, or hook up, the vetches before I could plough the land: but this is not often the caſe; when it is, the farmer has reaſon to rejoice.

"There are, as I hinted in the beginning of this account, ſcarcely any ſoils but the vetch will thrive in, though ever ſo various in their nature. I am an old man, and in the courſe of many years experience have ſown vetches often on a ſandy and gravelly loam, a chalk, though not for ploughing-in, a gravel, a low damp clay, and a perfect brown loam. On all theſe varieties of ſoil have they ſucceeded with me; but I muſt note, that the farmer may expect a larger crop from a gravel (I do not mean a pure gravel) that has ſome heart and ſtrength in it, than from the fineſt loam, which has been, by a long-continued courſe of bad culture, ſtarved and impoveriſhed.

"The large vetch may be ſown in January, February, March, April, or even the beginning of May, when deſigned for green fodder; but I would, by all means, have the induſtrious farmer avoid ſowing it before Chriſtmas,

for

for it is a tender plant, and if hard froſt enſue, he may chance to loſe his crop." *Muſeum Ruſticum*, *vol.* III. *page* 185.

VINEGAR, an acid penetrating liquor, prepared from wine, cyder, beer, &c. of conſiderable uſe both as a medicine and ſauce.

The proceeſs of turning vegetable matters to vinegar, is thus delivered by Dr. Shaw: take the ſkins of raiſins, after they have been uſed in making wine; and pour three or four times their own quantity of boiling water upon them, ſo as to make a thin aqueous mixture. Then ſet the containing caſk, looſely covered, in a warmer place than is uſed for vinous fermentation; and the liquor in a few weeks time will become a clear and ſound vinegar; which being drawn off from its ſediment, and preſerved in another caſk, well ſtopped down, will continue perfect, and fit for uſe.

This experiment ſhews us a cheap and ready way of making vinegar from refuſe materials; ſuch as the huſks of grapes, decayed raiſins, the lees of wine, grounds of ale, beer, &c. which are frequently thrown away as uſeleſs. Thus, in many wine countries, the marc, rape, or dry preſſing of grapes, are thrown in heaps, and ſuffered to putrify unregarded, though capable of affording as good vinegar as the wine itſelf. In ſome places they bury copper-plates in theſe huſks, in order to make verdigreaſe; but this practice ſeems chiefly confined to the ſouthern parts of France. Our preſent experiment ſhews us how to convert them to another uſe; and the direction extends to all the matters that have once undergone, or are fit to undergo, a vinous fermentation, for that all ſuch matters will afford vinegar. Thus all our ſummer-fruits in England, even black-berries; all the refuſe waſhings of a ſugar-houſe, cyder-preſſings, or the like, will make vinegar, by means of water, the open air, and warmth.

The whole proceſs, whereby this change is effected, deſerves to be attentively conſidered; and, firſt, the liquor to be thus changed, being kept warmer than in vinous fermentation, it begins, in a few days, to grow thick or turbid; and without throwing up bubbles, or making any conſiderable tumult, as happens in vinous fermentation, depoſits a copious ſediment.

The effect of this ſeparation begins to appear, firſt, on the ſurface of the liquor, which gathers a white ſkin, that daily increaſes in thickneſs, till at length it becomes like leather; and now, if continued longer in this ſtate, the ſkin turns blue, or green, and would at laſt grow ſolid, and putrify: therefore, in keeping down this ſkin as it grows, and thruſting it gently down to the bottom of the veſſel, conſiſts much of the art of vinegar making, eſpecially from malt. For the difference between vinous and acetous fermentation, *ſee the article* FERMENTATION.

Method of making Cyder-VINEGAR. The cyder (the meaneſt of which will ſerve the purpoſe) is firſt to be drawn off fine into another veſſel, and a quantity of the muſt, or pouz of apples, to be added: the whole is ſet in the ſun, if there be a conveniency for the purpoſe; and, at a week or nine days end, it may be drawn off. *See* CYDER.

Method of making Beer-VINEGAR. Take a middling ſort of beer, indifferently well hopped; into which, when it was worked well, and is grown fine, put ſome rape, or huſks of grapes, uſually brought home for that purpoſe: maſh them together in a tub; then, letting the rape ſettle, draw off the liquid part, put it into a caſk, and ſet it in the ſun as hot as may be (the bung being only covered with a tile, or ſlate-ſtone) and in about thirty or forty days, it will become a good vinegar, and may paſs into uſe as well as that made of wine, if it be refined, and kept from turning muſty.

Or thus: to every gallon of ſpring-water, add three pounds of Malaga-raiſins; which put into an earthen jar, and place them where they may have the hotteſt ſun from May till Michaelmas; then preſſing all well, tun the liquor up in a very ſtrong iron-hooped veſſel, to prevent its burſting: it will appear very thick and muddy, when newly preſſed; but will refine in the veſſel, and be as clear as wine.

Thus let it remain untouched for three months, before it be drawn off, and it will prove excellent vinegar.

Method of making Wine-VINEGAR. Any ſort of vinous liquor, being mixed with its own fæces, flowers, or ferment, and its tartar, firſt reduced to powder; or elſe with the acid and auſtere ſtalks of the vegetable from whence the wine was obtained, which hold a large proportion of tartar: and the whole being kept frequently ſtirring in a veſſel which has formerly held vinegar, or ſet in a warm place full of the ſteams of the ſame, will begin to ferment a-new, conceive heat, grow ſour by degrees, and ſoon turn into vinegar.

The remote ſubjects of acetous fermentation are the ſame with thoſe of vinous; but the immediate ſubjects of it are all kinds of vegetable juices, after they have once undergone that fermentation which reduces them to wine: for it is abſolutely impoſſible to make vinegar of muſt, the crude juice of grapes, or other ripe fruits, without the previous aſſiſtance of vinous fermentation.

The proper ferments for this operation, whereby vinegar is prepared, are, 1. The fæces of all acid wines. 2. The leys of vinegar. 3. Pulveriſed tartar; eſpecially that of Rheniſh wine, or the cream, or cryſtals thereof. 4. Vinegar itſelf. 5. A wooden veſſel well drenched with vinegar, or one that has been long employed to contain it. 6. Wine that has often been mixed with its own fæces. 7. The twigs of vines, and the ſtalks of grapes, currants, cherries, and other vegetables of an acid auſtere taſte. 8. Bakers leaven, after it is turned acid. 9. All manner of ferments, compounded of thoſe already mentioned.

The French uſe a method of making vinegar different from that above deſcribed. They take two large oaken veſſels, the larger the better, open at top; in each whereof they place a wooden grate, within a foot of the bottom: upon theſe grates they firſt lay twigs, or cuttings of vines, and afterwards the ſtalks of the bunches, without the grapes themſelves, or their ſtones; till the whole pile reaches within a foot of the brim of the veſſels: then they fill one of theſe veſſels with wine to the very top, and half fill the other; and with liquor drawn out of the full veſſel, fill up that which was only half full before; daily repeating the ſame operation, and pouring the liquor back from one veſſel into another; ſo that each of them is full, and half full, by turns.

When this proceſs has been continued for two or three days, a degree of heat will ariſe in the veſſel, which is then but half full, and increaſe for ſeveral days ſucceſſively, without any appearance of the like in the veſſel which happens to be full, during thoſe days; the liquor whereof will ſtill remain cool; and as ſoon as the heat ceaſes in the veſſel

veſſel that is half full, the vinegar is prepared: which, in the ſummer, happens on the fourteenth or fifteenth day from the beginning; but in the winter, the fermentation proceeds much ſlower: ſo that they are obliged to forward it by artificial warmth, or the uſe of ſtoves.

When the weather is exceeding hot, the liquor ought to be poured off from the full veſſel into the other twice a-day: otherwiſe, the liquor will be overheated, and the fermentation prove too ſtrong; whence the ſpirituous parts will fly away, and leave a vapid wine, inſtead of a vinegar, behind.
